As previously stated, Dr. C. W. More of Eveleth came to Minnesota in the late eighties, was with Dr. Shipman at Ely for several years, then left and took a postgraduate course in New York, returning, as he says, broke financially. About this time, Mr. George St. Claire was opening a mine in Eveleth and upon the advice of friends, Mr. Joseph Sellwood and Mr. O. D. Kinney, Dr. More accepted a position as physician for the company at Eveleth. Dr. More states in his "Reminiscences of a Range Physician" that he came to Eveleth in June, 1894. The town had been started the year before, but hard times came on and it was partially deserted.

"When I arrived there was a saloon, a boarding house, three or four families, and a few shacks and tents where some of the miners lived. With borrowed money I bought a few drugs and dressings, a second-hand bed spring, a cheap mattress, moved into an unfinished and abandoned saloon shack, and took my meals in a large tent with the other mining employees. This dining tent was located near a small creek one could jump across. A hole had been dug near it by the proprietor of the tent, who was also the cook, to furnish water for washing clothes, dishes, et cetera. The summer was hot and dry. The inside top of the tent was black with flies. Typhoid fever resulted. The sick were cared for in tents, shacks, or wherever they lived. I was doctor and nurse, bathing the men, shaking out the dusty and dirty blankets and sheets if they had any. Most of the patients ran a temperature of 104 and 105. Some had complications. By September, the weather was getting colder. I had been running a low temperature for about three weeks, but kept going until one morning I did not have enough ambition to get up until someone came and wanted to know why I didn't go to see my patients. I was sent to St. Mary's Hospital in Duluth, where Dr. Sam H. Boyer, Sr., took care of me for two months. Drs. Bates and Miller of Virginia took care of the sick typhoid patients after I left. None of the patients in this epidemic of typhoid died. After leaving the hospital, I was laid up with phlebitis for three months. I returned to Eveleth in February, 1895. I went to work again considerably handicapped this time by being obliged to use a cane. I kept as an assistant the young physician who had been looking after my work during my absence, Dr. Darms. We had no hospital, but there was an empty one-story building boarded on the inside of the studding which we had made habitable by boarding up to the ceiling of the first floor on the outside and nailing some building paper on the inside and filling the space with sawdust. I put up two beds and heated the room by the box stove I had bought five or six months before. This makeshift camp served for a hospital for several months, when I had another one built, 25 x 40 feet, one story, but warmer and plastered, and filled with hospital beds. At one time we had nine patients with fractures, including a broken spine and a crushed pelvis."

This story of Dr. More's early experiences as a pioneer physician at Eveleth no doubt is illustrative of what most of the older pioneer physicians of the Range experienced. Dr. More is still on the Range at Eveleth. He probably has been in continuous practice for the mining companies on the Range longer than any other physician. He is Dean of Medicine on the Range. His long years of faithful service and devotion to his patients and to the practice of medicine, his fine char-

acter and unfailing integrity and absolute honesty entitle him to the greatest respect and honor. That his medical friends and lay friends are not unmindful of this is shown by the fact that they gave him a testimonial dinner in recent years as a token of their appreciation of him as a friend and physician.

Among Dr. More's early assistants were Dr. H. A. Darms, in 1894, previously mentioned, Dr. Wolner, Dr. E. B. Daugherty, now retired and living at Marine-on-St. Croix, and his brother Dr. L. E. Daugherty or Saint Paul, Dr. J. E. Arnold, now of Montana, Dr. F. J. Pratt, now of Minneapolis, Dr. W. A. Day, the late Dr. Fred Barrett, in 1898, and the late Dr. F. W. Bullen of Hibbing, in 1900. Dr. A. W. Shaw of Buhl became Dr. More's assistant in 1899, but left the More Hospital staff and moved to Buhl in September, 1901, and opened a temporary hospital in a store building. He was with Dr. More during the first smallpox epidemic in Eveleth, also during the time the town was moved from the Spruce Mine to its present site.

Buhl was organized in 1899, at the time of the opening of the Sharon Mine. The town was named after Frank Buhl of Sharon, Pennsylvania. Dr. Stuart Bates of Virginia, Minnesota, was the first physician in charge. Later, the Sharon Mine office was converted into a hospital.

Dr. Shaw was the pioneer physician of Buhl. His first assistant was Dr. R. R. Bailey, now of the Bailey Lumber Company. Dr. Shaw built a new hospital in 1918, and this was sold to the County in 1931, and is now used as a County Hospital. Dr. Shaw was at one time assistant in anatomy at the University of Minnesota under Prof. George A. Hendricks. Dr. Hendricks had previously been in the anatomy department at Ann Arbor, associated with the great anatomist, Corydon Ford.

The late Dr. Kirk of Los Angeles was one of the early physicians at Chisholm.

Associated early with the Rood Hospital was Dr. E. H. Nelson, who is still in Chisholm.

There have been many assistants or associates to these pioneer physicians of the Range, some of whom have become very prominent in medicine and surgery. Among them may be mentioned Dr. J. P. Sedgwick, Professor of Pediatrics at the University of Minnesota until his death, who was formerly with Dr. Harwood. Dr. George F. Dick, of Chicago, Department of Medicine, University of Chicago, who has done so much work in scarlet fever, was with Dr. Shaw about the years 1908-1909, leaving Dr. Shaw to study in Vienna. Dr. Frank Hirschboeck, prominent physician of Duluth, also was with Dr. Shaw a number of years. Dr. L. E. Daugherty, one of the prominent surgeons of Saint Paul, and his brother, Dr. E. B. Daugherty, were formerly associated with Dr. More at Eveleth. Dr. Robert Rizer, of Minneapolis, was formerly associated with Dr. Shipman at Ely, leaving Ely to become associated with Dr. Bertram Sippy of Chicago.

The late Dr. T. W. Stumm of Saint Paul was associated with Dr. Rood at the Rood Hospital at Hibbing. Dr. F. W. Schultz, Professor of Pediatrics at the University of Chicago, was on the Range for about one year, 1908-1909, at the Fabiola Hospital, Eveleth, associated with Dr. Harwood.

It may be said of the pioneer and early Range physicians that they were well-trained men and good doctors. Most of the men who came to the Range had had hospital internships and experience in hospital work before the medical schools of the country were requiring internships before graduation. The communities of the Range have been furnished with hospitals very early in their development and growth. Thus they have received a service which was not general over the State of Minnesota, at that time. These hospitals of the Range, that started almost with the beginning of the towns, have rendered a wide variety of service to almost

every individual in the town, from the very minor things in surgery and medicine to the most complicated medical and surgical service, through their staff of physicians.

The Range Medical Society, organized a few years ago by the Range physicians as a subsidiary of the St. Louis County Medical Society, is a live, active organization, having had many excellent papers presented by men from Duluth, the Twin Cities, and Rochester, and having carried on postgraduate courses nearly every year in connection with the University Extension.

It is a far cry from the Iron Range of the day when Dr. Shipman walked through the muskeg swamp into Ely, when Dr. More settled in a saloon shack in Eveleth, when Dr. Rood first entered and saw the very beginnings of Hibbing, richest village in the world, and Dr. Shaw left Virginia on the "Old Wooden Shoe" at Gary, arriving at Buhl at 2 p. m., getting off at Buhl Station, a box car on a side track, and walking through a swamp on pole stringers, to find the Main Street of Buhl full of stumps. Yes, a far cry to the Range of today, with paved roads, white ways, wonderful school buildings, city halls and community centers, and hospitals, both general and contagious, a marvelous development to have occurred in the lifetime of a pioneer doctor. The frontiers of America have disappeared. The pioneers are fast disappearing, but when the last one has passed over the great divide, may the spirit of the Pioneer still live on, and may America never lose it.

(To be continued in July issue)

Western Electric 3-A Electrical Stethoscope

This portable electrical stethoscope is designed to aid the physician in hearing heart sounds and in diagnosing heart ailments. It has been developed particularly for physicians with impaired hearing, according to the firm. However, it is equally recommended to physicians with normal hearing in examining thick-chested individuals or detecting heart conditions during their early stages. It is claimed by the firm that other useful applications will be found in obstetric and lung fields. The Electrical Stethoscope essentially consists of a sensitive microphone, a vacuum tube amplifier and a receiver to reproduce the sounds. The two-stage amplifier, operated by dry batteries, will increase the loudness of the heart sounds about 20 decibels, or 100 times the intensity obtained with an ordinary acoustical stethoscope. The amplifier contains a filter which may be cut in or out of the circuit by means of a switch. The filter control diminishes the response at both the low and high frequencies; thus the intensity of normal heart sounds is lowered and the loudness of any existing murmurs is accentuated by the isolation. The Council reported that the instrument distorts in a measure the heart and breath sounds so that a certain amount of experience is necessary to learn the normal sounds as produced by it. Western Electric Company, New York. (J.A.M.A., April 2, 1938, p. 1111.)

Volume 21 JUNE, 1938 Number 6

State Meeting

THE stage is set for our annual meeting which is to be held this month in Duluth, almost two months later in the year than last year's meeting in Saint Paul. The time of meeting has been so planned that those attending can spend the week-end over the fourth of July in recreation in the north woods.

Perusal of the program, which appears in this number of the journal, shows that the main meetings of the Council and House of Delegates will be held in advance of the scientific sessions so as not to interfere with attendance at the general assemblies, which will this year replace sectional meetings. With clinics the third day, the program will occupy three instead of two days.

Nine outstanding specialists will appear as guest speakers on the program. Dr. Irvin Abell of Louisville, president of our national association and an outstanding surgeon, will address the Public Health meeting, open to the public, on the aims of the profession as they relate to the public. He will also give a talk to the profession on cancer. We all know of Dr. Howard W. Haggard of Yale, author of "Devils, Drugs and Doctors," who is equally famed as a public lecturer. He will address the Public Health meetings and will speak at the banquet Thursday evening.

Members of the Women's Auxiliary of the State Medical Association and the wives of state members who are not Auxiliary members are urged to attend the convention. In addition to the regular annual Auxiliary meetings, the St. Louis County Auxiliary members have arranged entertainment for visiting ladies, outstanding being a boat trip on Lake Superior on the Canadian liner Hamonic, on Friday.

The golf tournament for Association members is scheduled for Saturday following the meeting. For those who have never played the Northland course, there is the experience in store of watching a golf ball defy the laws of gravity by rolling up hill on the greens.

Some twelve hundred physicians are expected to attend the meeting. While most of those attending will be from Minnesota, an increasing number from neighboring states have been taking advantage of the scientific program in recent years and are again being invited to attend.

The Army Medical Library and Museum

THE present building of the Army Medical Library and Museum at Seventh Street and Independence Avenue in Washington was constructed by Congressional appropriation in 1887 and is now entirely obsolete and inadequate. Now pending in Congress is a bill providing for the appropriation of $3,750,000.00 to replace, in a better location, the present building with a modern fireproof structure of a type and style commensurate with the importance of this unique collection of books and specimens.

The Army Medical Library, now the largest

medical library in the world, was established in a small way by Surgeon General Lovell in 1836 and was known for many years afterwards as the Surgeon General's Library. It now contains approximately 500,000 books on medical subjects and, with the pamphlets, theses and other manuscripts, its collection numbers over a million separate items. By Acts of Congress of 1892 and 1901 the Library and Museum have been available to all scientific bodies and students. Thousands of readers and writers visit the Library yearly and by its inter-library loan system any reputable physician or scientist in this country may obtain any but the rarest books in its collection by making his request through the nearest library. It is the great central repository of medical literature, old and new, and contains many rare books, among them being about 460 of the existing 600 medical incunabula, or books published in the cradle age of printing, before 1500.

The oldest publication possessed by the library is Johannes Gerson's "De pollutione nocturna," printed in Cologne, in 1467, the only copy in the United States. Other rare old books are "Speculum humanæ vitæ" by Rodericus Zamorensis, printed in Rome in 1468, while among early writings on plague are "De epidemia" by Valescus de Taranta, Basel, 1470 and "Regimen pestilentiæ" by Alcanis Luis, printed in Valencia about 1490. The library has also a perfect copy of the first printed book on pediatrics, Bagellardo's "De infantium ægritudinibus," Padua, 1472, one of the two copies in the United States. Many of the incunabula are first editions. "De medicinis universalibus" by the Arabian physician Mesue the younger, printed in Venice in 1471, is the first purely medical book ever printed in the world.

The Library now receives two thousand medical journals and indexes every important article from every journal regardless of its country of origin or its language. The Index Catalogue of the Army Medical Library is world famous and has been in existence since 1879. It was characterized by the late Professor Welch of Johns Hopkins University, with the library itself, as "America's greatest gift to medicine."

The Army Medical Museum, now containing the largest number of pathologic preparations in America, was started in 1863 with specimens from the hospitals and battlefields of the Civil War, and its enormous collection now covers the entire field of pathology. It maintains registries in seven important fields: eye, ear, nose and throat pathology, bladder tumors, lymphatic tumors, tumors in general, skin pathology and dental and oral pathology, all sponsored by national organizations interested in these various subjects, collecting and assembling the specimens with all available data in systematic fashion for ready consultation. With the Library, the Museum and the Index Catalogue, every resource for writing or research in any subject of any field of medicine is available under one roof. To the genius and industry of John Shaw Billings, whose career was epitomized in the editorial columns of Minnesota Medicine last month, is due the development of these three great activities, and the entire medical profession has been the gainer therefrom. It is little enough, it seems to us, that we lend our support to this movement to secure adequate housing for these priceless collections of books and specimens, where they may continue to give aid and support to the cause of scientific medicine.

G. C.

Insulin a Life Saver

SEVERAL years ago (1931) we called attention to the rise in the death rate from diabetes mellitus which had been unaffected by the discovery of insulin.* The death rate from diabetes had increased from 15.9 per 100,000 population in 1912 to 23.3 in 1928. In 1936 it had not receded and was 23.7. The explanation for such an unexpected increase was that either diabetes is more often diagnosed or is on the increase, or both.

How much of a boon insulin has been to diabetic individuals is well presented in a statistical analysis† of 2,271 deaths in diabetic patients seen by Joslin at the Baker Clinic in Boston between 1897 and 1928. The analysis of such statistics belongs to the sphere of the expert statistician and we are content to abide by the conclusions drawn by Dublin.

The patients are grouped according to the

*The Strange Case of Diabetes. Editorial. Minn. Med., 14:560, 1931.

†Joslin, E. P., Dublin, L. I., and Marks, H. H.: Studies in Diabetes Mellitus, VI, Mortality and Longevity of Diabetics. Am. Jour. Med. Sci., 195:596, 1938.

Naunyn period (1897-1913); the Allen period (1914 to 1922); the first Banting period (1922-1925), during which the medical profession was learning how to use insulin; and the second Banting period (1926-1928), when the best results of insulin therapy could be evaluated. The conclusions present in concrete form the progress made in the prolongation of life by the development of new and better methods of treatment.

Roughly speaking, the death rate in these diabetic patients fell a third in the Allen period compared with the Naunyn period, and in the second Banting period was 74 per cent lower than in the Naunyn period. The most marked improvement was in children, and comparing the Naunyn and second Banting period, the mortality for the first two decades of life was reduced 98 per cent, for the third decade 95 per cent, and for the fourth and fifth decades 80 per cent.

In the group of diabetic patients investigated the life expectancy for children under ten years of age jumped from a little over one year to thirty-three, and at the age of twenty increased from two and a half years to twenty-eight. The increases in later periods of life, while less startling, were, however, substantial, for at the age of forty the gain was eleven years and at sixty about four and a half years.

While the mortality in diabetic individuals in the group analyzed is still higher than that in the general population, it being six times as great in the younger groups and twice that in the older groups, the improvement that modern treatment, and especially the use of insulin has afforded, is nicely shown in this analysis.

Gonococcus Filtrate (Corbus-Ferry) Not Acceptable for N.N.R.

Since 1931, the Council on Pharmacy and Chemistry has considered from time to time this product, which is a gonococcus bouillon filtrate proposed for the treatment of gonorrhea and marketed by Parke, Davis & Co. Two preliminary reports have been published (*The Journal*, Feb. 13, 1932, and May 18, 1935), and each time the Council has postponed consideration to await the development of more convincing evidence of the therapeutic value of the product. In the meantime the firm has made efforts to collect the needed clinical data and has abstained from promoting the product actively. The occasion of the Council's latest consideration of the product was the presentation by the firm of a booklet with references to recent literature concerning Gonococcus Filtrate (Corbus-Ferry). The Council considered the literature cited by the firm, together with other reports which were available, and concluded that satisfactory evidence for the use of this product is lacking. Gonococcus Filtrate (Corbus-Ferry) (Parke, Davis & Co.) was therefore declared not acceptable for N.N.R.—(J.A.M.A., Jan. 1, 1938, p. 47.)

In Memoriam

F. Emerson Daigneau

1862-1937

DR. F. EMERSON DAIGNEAU was born at Hubbardton, Rutland, Vt., Ocober 1, 1862, and got his early education in the schools of that village. After attending Newton Academy at Shoreham, Vermont, he followed this with a course in the college at St. Hyacinthe, in the Province of Quebec. Later he went to New York and by his own resources worked his way through college there. He returned to Vermont and entered the medical department of the University of Vermont, graduating from there at the head of his class in 1886, with the degree of Doctor of Medicine. He received the highest honors of his class and the first prize established by the faculty for "general proficiency in examinations."

Dr. Daigneau practiced for a time at Somersworth, N. H., a year later came west to Saint Paul, and shortly thereafter came to the then growing city of Austin, where he remained until his death December 10, 1937. He was at one time a member of the Mower County Medical Society and the St. Olaf Hospital staff.

Dr. Daigneau was married March 31, 1888, to Miss Alice Merrick, of Somersworth, N. H., who survives him. He is also survived by six children: Donald V. and Ralph H. of Austin, Kenneth S. of New York, Maurice of Cleveland, Marcia L., now Mrs. P. H. Macfarlane of Chisholm, and Elizabeth A., now Mrs. T. E. Linnihan of Everly, Iowa.

Charles M. Storch

1870-1938

DR. CHARLES M. STORCH was born in Milan, Ohio, in 1870, and died March 13, 1938, at his home in Biloxi, Mississippi, after an illness of three years' duration.

Dr. Storch received his medical degree from the University of Michigan in 1891, after which he studied a year at the New York Polyclinic. He then became associated with his uncle, Dr. Charles Stewart, in Duluth. Moving to Grand Rapids, Minnesota, he devoted himself there to general practice for thirty-three years, until 1935, when he went to Minneapolis. Ill health prevented his carrying on active practice in Minneapolis.

Dr. Storch's father, Dr. August von Storch, was a graduate of Heidelberg University and for many years was a well known medical authority in Washington, D. C. He is survived by his widow, a half brother, Dr. Raymond Storch, a lieutenant commander in the United States Navy, and a step-son, Ralph E. Dawley, of Long Beach, California.

Dr. and Mrs. Storch moved to Biloxi about a year and a half ago, to occupy a home they had built there.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association

W. F. Braasch, M. D., Chairman

SURVEY PROGRESS

Form No. 1 of the Survey on Medical Care was sent in May to all secretaries of county and district medical societies in Minnesota for distribution to members.

These forms should be filled in carefully and returned UNSIGNED to the county or district secretary.

The objective of this Survey is, fundamentally, to find out how many there are who are going without needed medical care and why.

This objective cannot be accomplished without the active interest and assistance of every physician.

HAVE YOU FILLED OUT AND RETURNED YOUR FORM?

If not, you should do so immediately. This is the most important task before American Medicine today.

The bulletin and instruction sheet which accompanied the Form is printed below in the hope that it will serve to re-emphasize in the minds of all physicians the importance of their part in this nation-wide effort.

Your Professional Future Is at Stake

Our whole system of medical practice in the United States has been challenged. There is criticism of the medical profession and of the adequacy of medical care on all sides.

ARE WE FAILING TO DELIVER ADEQUATE MEDICAL CARE TO ALL THE PEOPLE?

If we are, we must know the facts. Other groups who have attempted to study medical care have not presented a true picture of conditions because they have not had the active participation of the physician, who is the chief factor in the delivery of medical care in the United States.

NOW—THE AMERICAN MEDICAL ASSOCIATION, WITH THE ASSISTANCE OF HOSPITALS, NURSES, DENTISTS, PHARMACISTS, IS UNDERTAKING AN ACCURATE, HONEST, COUNTY-BY-COUNTY STUDY OF THE FACTS.

THIS IS YOUR STUDY—AND THE RESPONSIBILITY FOR MAKING NEEDED IMPROVEMENTS AS DISCLOSED IN THIS STUDY WILL BE YOUR RESPONSIBILITY. ABOVE ALL IT IS NOT TO BE JUST ANOTHER STATISTICAL EXERCISE TO BE FILED AWAY AND FORGOTTEN.

Following are the instructions for fill-out Form No. 1. They are numbered according to the question in each case. Forms are to be returned to me* *unsigned.*

1. If you have no exact figures, make a careful estimate.
2. Relief, Old Age Assistance, Farm Security patients, etc., included.
3. Make as accurate an estimate as possible.
4. Exact figures should be available here in most cases.
5. This refers to private practice as well as to public health services.
6. Make this reply as exact as possible.
7. This question should be answered frankly and fully.
8. Exact figures if available; otherwise give a careful estimate.
9. This is important. Answer in detail using extra sheet if needed.

*Secretary of Society.

Teachers Respond

Officers in charge of the Survey in Minnesota have been especially interested to note the enthusiasm and promptness with which other agencies have responded to the request for assistance in gathering pertinent information from their own records and experience.

Hospital, nursing and welfare organizations have taken an official hand in sending the appropriate forms to their member groups. The State Department of Education has sent forms to all superintendents of public schools in the state. Information is coming in rapidly from parochial and Catholic high schools all over the state and from the colleges, all of whom are communicating directly with the State Office.

Interest Is Keen

The speed and alertness exhibited by the principals of the Catholic secondary schools in responding to the request is an encouraging indication of the interest of these educators in the

health of their charges and in the effort of the physicians to make accurate studies of their needs.

Below are comments selected at random from the large number of questionnaires already returned in spite of the fact that they reached the desks of the Sister Principals in the busiest month of the year.

It should be noted that a significant number attribute lack of proper care among their pupils to parental neglect.

It is obvious, also, in these comments that, while county medical societies are shouldering their responsibilities in many communities, in others not even a nurse has interested herself in the health of the school for years. It is the hope of the committee in charge of the Survey that this study will bring home to doctors everywhere the need to correct such situations as this wherever they are found. If the interest is great enough, some arrangement can always be made, and the best arrangements, as these answers indicate, are in the communities where the local doctors have taken a hand.

* * *

"We believe an annual dental examination would prove a great benefit. As there are several pupils in each classroom of our school who need glasses, a check-up on sight would be a great help."—Madison.

Parents Careless

"Arrangements for health supervision are made chiefly by the teachers and by the parents in our school. Nothing special is done in this line. The county nurse should do it but has not come around within five years or more. The fact is that even if the parents are told to take their child to a physician, it is not done. Many of our children lack needed medical care but it is due chiefly to carelessness on the part of the parents."—Collegeville.

* * *

"Every fall the physicians and a dentist from town come to examine our pupils but do not give free treatments. Last fall all our children were immunized against diphtheria and vaccinated for smallpox. The charge was 50 cents for each child. Our children are fairly well taken care of by their parents. We know of but one family that is in great need of medical care but has not the means to meet expenses. There ought to be a general fund to provide for this deficiency."—Loretto.

Legion, Lions Assist

"The local American Legion has sponsored a health program in the local schools the last two years. Previous to that we had a county nurse for a brief period of time. She visited the schools once during a term. Due to our doctors from both clinics who offered their services gratis and also to the coöperation of the able chairman of the American Legion Auxiliary, all the children whose parents consented were both vaccinated and immunized against diphtheria.

"Our pupils who suffered from poor eyesight and were too poor to pay for medical care of glasses were cared for by the local Lions' Club.

"The superintendents of the various schools here have agreed on engaging a nurse for the coming school term. Each school has been taxed for the purpose and our Reverend Pastor and his trustees will pay their apportionment."—Wadena.

"They Would Be Well Served"

"Arrangements with the county medical society were made for free vaccinations of whole families of indigent children. The people in this community would be well served if they took advantage of all services offered either free or at a small cost . . ." —Minneapolis.

* * *

"We as teachers feel that something should be done. We positively know that some pupils need medical attention for teeth, eyes, undernourishment, etc. Some children, for example, can read only when their eyes are at a certain angle. We have asked the parents to look after these children but we must have influential coöperation."—New Market.

* * *

"The need for medical care among the children of this particular school seems not great as the parents take exceptionally good care of them and willingly coöperate in any measures which are proposed to safeguard their health. From the standpoint of the teacher, however, it would be immeasurably valuable to us if through complete physical examinations we could become acquainted with the physical status of our children. Experience has taught us that often retardation is due to some unknown physical defect. If the health department is not able to appoint doctors to conduct these examinations periodically perhaps volunteers from the medical profession would give a day or a half-day to this work."—Minneapolis.

Need Nurse

"Common colds and coughs are greatly neglected. Skin diseases have gained some headway this year. A number of our pupils' eyes have been examined by oculists at our suggestion. We should deem it advisable to have the services of a nurse at least once a year."—Kimball.

* * *

"Some arrangements should be made for dental treatment or clinics for parochial schools. Ancker Hospital and Wilder Dispensary are overcrowded and do mostly extractions. Indigent pupils and those that could pay a little must neglect their teeth until decay progresses far enough for extraction."—Saint Paul.

* * *

"The county nurse visited our school once in four years. We have no doctor in this town."—Greenwald.

* * *

"No physician or nurse has called here since 1936. We have had good attendance at school this past school year and very little sickness. If any child living near by is sick we send him home immediately; if he lives at a great distance and has no telephone at home we give as much relief as we can by applying home remedies."—St. Leo.

* * *

"Three or four promises have been made to inspect our children; however, none was kept. We have received no attention this year."—Virginia.

Thanks to Doctors

"The medical care of the boys in this school is excellent—thanks to the splendid men of the Minnesota Medical Association who give generously of their time and service."—Minneapolis.

* * *

"Both medical and dental societies are willing to give treatment free of charge to pupils who are in need of such service."—Faribault.

BUTTER SUBSTITUTE CONTROVERSY

Did the A.M.A. discriminate against butter in favor of oleomargarine?

It did not.

Why did the A.M.A. refuse to standardize butter?

Because they found it impractical with their limited resources to inspect and standardize the innumerable brands and the constantly changing character of butter.

Their action was taken with no intent whatever to discriminate against butter in favor of any other product.

They took it for granted that everyone knew that natural butter fat was preferable to any substitute.

They also knew that Federal inspection was available to any producer of butter who wishes inspection and certification.

Why then did the A.M.A. continue to standardize and grade substitutes for butter fat?

Because there are many brands on the market which are being consumed by the public, some of which are of much higher nutritional value than others.

The public had no means of determining their comparative value.

The A.M.A. approved those brands which on analysis had the greatest food value. In this way the interests of the public were protected—not the manufacturers.

Such action in no way discriminated against butter or the farmer.

Iowa Protest

The Iowa State Medical Association passed a resolution on May 13 protesting the acceptance of substitutes for dairy products. The action was taken, without doubt, because of local agitation among Iowa dairy farmers and manufacturers of dairy products.

There has been similar agitation in Minnesota; but most physicians and others in Minnesota realize well the position of the American Medical Association. They know that everybody, including the "oleo" manufacturers, are aware of the superiority of butter as a food to any of its substitutes. They also know that there are millions of people in some sections of the United States who cannot afford to buy a sufficiency of dairy products for their families. People demand and use a cheap substitute and they are entitled to know, if possible, whether wholesome materials are used in the substitute and whether or not it is produced under wholesome conditions.

Public Duty

In investigating these substitutes as they apply and awarding the Seal of Acceptance to those whose materials, manufacture and advertising claims live up to the high standard of the Council, the American Medical Association is performing an essential public duty.

The fact that the Council on Foods was not influenced by the indignation of an important legitimate industry which it must have known would rise against it, is another sign of integrity. This integrity must be maintained, no matter what opposition may be stirred up, if the Council on Foods or any of the Councils of the American Medical Association are to perform a useful function.

MINNESOTA ATTORNEY GENERAL RULES IN FAVOR OF FREE CHOICE OF PHYSICIAN

The Honorable William S. Ervin, Attorney General of the State of Minnesota, has recently issued a ruling that is not only of great interest, but of real importance, to the medical profession of Minnesota. The ruling concerns the right of a person on relief to select his own physician. Following an exhaustive study of the matter, Mr. Ervin has ruled that a person on relief may select his own physician, and cannot be required "to go to the county physician if such person desires to use the services of another physician who conforms to the regulations of the Executive Council and of the responsible relief agency."

Section 11 of Chapter 89 of the Extra Session Laws of 1937 provides in part:

"All counties shall permit free choice of vendor to relief clients for relief orders, provided that the vendors thus chosen conform to the regulations of the Executive Council and of the responsible relief agency."

The question presented is whether or not "free choice of vendor" includes the services of a physician. Mr. Ervin points out, in his opinion, that the purpose of construing the law "is to ascertain and give effect to the intention of the legislature." He then goes on to point out that, following the enactment of this law, the State Relief Department on September 22, 1937, issued an administrative letter to all county welfare boards in which it was stated that persons on relief should be permitted to select their own doctor. That letter contained the following statement:

"Client will request Medical Relief Order from county worker. If qualified, he will be given order on SRA Form No. 94 addressed to physician, hos-

pital, or other vendor who is selected by client. This form will be presented to vendor, physician, dentist, hospital, or other, and will be authority for rendering the specified service. Responsibility for medical care is not accepted without his order except in emergencies."

Mr. Ervin richly deserves the thanks not only of those persons who are so unfortunate as to be out of work and on relief, but also the appreciation of each and every member of the medical profession, for his broad and fair-minded interpretation of this law. It seems only right and proper that when free choice is permitted as to the every-day commodities of life, such as food, clothing, etc., the principle of free choice of physician should be preserved.

MEDICAL CARE IN THE DOMINION

New plans for delivery of medical service are being worked out on an extensive scale these days by Canadian medical associations and the provinces and municipalities.

This development should be of great interest to physicians of the United States because conditions and people in various sections of Canada more nearly resemble those below the border than in any other country in the world.

Looking to England

It is quite natural, of course, that there should be a sympathetic feeling toward health insurance among a good many Canadian physicians since Canadians normally look to England to lead the way in many fields. It is interesting to note, however, that, where the mother country rushed headlong into health insurance and spent twenty-five years patching up discrepancies and undoing blunders, Canada is proceeding cautiously, gathering statistics, making local studies. If health insurance should ever become a reality there, on a national scale, it will be with full knowledge that the needs in the Western Provinces are quite different from those in the urban centers and that many little plans must be made to fit into the general pattern.

This was the gist of an address by Dr. F. W. Jackson, Deputy Minister of Health of the Province of Manitoba, before the Conference of State and Provincial Health Authorities of North America in Washington recently. Following are some of the types of service now in operation in various parts of the Dominion as described by Dr. Jackson:

The Municipal Doctor System. By this system the municipality, local unit of government in Western Canada, covering an area of from 200 to 300 miles with a population of from 1,500 to 3,000 persons, hires the doctor on a salary basis. The salary varies from $3,000 to $4,000 yearly with certain perquisites and allowances for leaves to take post-graduate work, attend meetings. The municipal doctor is health officer and physician and he has the right to charge for a certain portion of his services.

System Is Spreading

This type of service has extended of late until it covers more than one-fifth of the rural municipalities of Saskatchewan already, with as many more preparing to institute similar plans. In Manitoba nine rural municipalities are receiving medical care under the plan with three or four others preparing to join them and two providing similar care for their urban residents on a *fee for services rendered basis.*

Lump sum basis with free choice of physician. In the Province of Ontario the Provincial government pays over to the medical profession a definite amount, varying from 35 to 50 cents per head, for medical care of the unemployed. The profession in return sees that care is provided. The doctors have divided the province into 11 districts with a local committee of physicians to supervise the service and distribution of funds for the district. The physicians send an account of services rendered at the end of each month, using the regular schedule of fees, and the physicians' committee prorates the total amount available. It appears to work out at about 40 per cent of regular fees paid to the physicians who do the work.

In the western provinces the same type of plan is operating in the cities.

Like Minnesota Plan

Fee basis with free choice of physicians. In Winnipeg a system of services upon a special fee basis has been set up with much the same type of regulation as governs medical care for the indigent in the majority of Minnesota counties. The city provides the funds but the administration is under complete control of the medical profession through a medical advisory committee which has

authority to settle all disputes that may arise. The same plan is followed in most of the other cities in the Province of Manitoba.

It should be interesting to Minnesota physicians to note that in Manitoba wherever the service is in charge of the Manitoba Medical Association, a deduction of 5 per cent is made on all doctors' accounts. This 5 per cent is paid into the funds of the Association for defraying costs of supervision. It has resulted in the accumulation of a considerable sum of money above and beyond the amount needed to administer the service and this fund is to be held, according to Dr. Jackson, "in a trust fund to be used if and when consideration is given to some province-wide form of state medicine or health insurance."

Statistics for the Future

"The information obtained from the returns of the physicians under the plan in operation in Winnipeg," Dr. Jackson also remarked, "has been tabulated from year to year and we are now getting a fund of statistics which will be of real value in estimating the amount and type of illness and its requirement in terms of medical care in an urban community."

Health insurance acts have been passed in Alberta and in British Columbia. In Alberta, although the act was passed in 1934 setting forth all details, the plan has as yet not been put into operation. In British Columbia, as noted previously in these columns, the opposition of the organized medical profession has made it impossible to establish the plan. The opposition, according to Dr. Jackson, was due chiefly to the decision of the government not to include indigents in the scheme. A plebiscite on the question which took place in the summer of 1937 is said to have revealed public opinion in favor of some sort of Health Insurance.

"What the future may hold," said Dr. Jackson in conclusion, "remains to be seen; but one fact is apparent—as yet we have not the required information in Canada to allow us to set up in all its details, with any degree of actuarial accuracy, a scheme of adequate medical care for all groups of our population. We must get more information as to the amount and types of illnesses among the various groups of our population in the different sections of Canada and it would seem unwise for the Dominion or any province to embark on a wholesale scheme for the provision of medical care until such time as this information is available."

U. S. Needs Facts

In the United States there is no interest in wholesale changes in medical practice on the part of any but isolated groups. The reason is doubtless because medical care has been much better distributed and is much more easily available in most parts of the country than in the Dominion.

The same need for exact information exists here as in Canada, however, though for a somewhat different reason. Medicine in the United States has been definitely challenged. If the system in general is adequate, we must have facts to prove it. If it is not adequate, we must be ready, on the basis of accurate information, to make whatever changes are needed in the places where they are needed.

This is a doctor's job.

EFFECTIVE ORGANIZATION—DOES IT PAY?

(Monthly Editorial Prepared by the Medical Advisory Committee)

Says William L. Ransom, Past President, American Bar Association, in a recent address at the annual meeting of the Federation of the Bar Association of Western New York, speaking of the greater cohesion and efficiency of the medical profession as compared to that of his own association:

"One of the striking variances, which is probably responsible for a great deal of the greater unity and effectiveness of the medical organization, is the fact that the latter has been able to prove itself useful to its members, in practical ways. A physician needs and wants to belong to the organization of his profession, if he can possibly get in. Membership is looked on as a certificate of professional standing, and the Association has developed a capacity for supplying the average medical doctor with factual data and experience which are highly useful to him in his professional work. The medical organizations have made themselves virtually indispensable to the average practitioner in the field of medicine.

"Neither the American Bar Association nor the State Bar Association have as yet developed any such propensity or capacity."

So speaks a man looking in. Your Medical Advisory Committee believes that no greater compliment could be paid to us and our organization than this by one who has held high office in the Bar Association. Are you as a member of the Minnesota State Medical Society doing your share to promote effective organization and personal harmony among your colleagues? Does it pay to promote greater unity of purpose among our membership?

ECONOMICS SESSION

Chief Justice H. M. Gallagher will be principal guest speaker at the annual Medical Economics session to be held in connection with the State Meeting at Duluth, June 29, 30 and July 1.

Medical jurisprudence and our relations with the Bar have a place of particular prominence at this session. The second speaker is Mr. Stanley B. Houck of Minneapolis, Chairman, Standing Committee on Unauthorized Practice of the Law, American Bar Association.

Following these two talks scheduled for Friday morning, July 1, Dr. J. M. Hayes of Minneapolis will give the annual president's address. The subject, "Medical Problems in Minnesota," is timely and the active participation of President Hayes in medical, medical-economic and sociological affairs of the society assures a vigorous and individual paper.

"THE COMMUNITY PAYS"—Parran

"The community pays for preventable disease and disability. It pays in relief of the unemployables, in pensions and in institutional care. It would be cheaper for us as a nation to spend more for the prevention and care of disease than to continue to bear its money cost. It is, therefore, not only the humane but the practical consideration which brings to our attention the acute need for dealing courageously with unnecessary sickness in this country. Our efforts up to now have been sporadic, half-hearted, and frequently unscientific. The time seems opportune for the best minds in the medical profession to consider how medical knowledge can best be brought to fuller use by all of the people—how we may take up the lag between what we know and what we do. It should be possible for a national health program to be evolved which would be adapted to the varying needs of each state and community.

A practical program to utilize our scientific resources for life-saving would bring advantages to our profession almost as great as to the population which would be served."—Surgeon-General Thomas Parran, U. S. Public Health Service, before the Conference of State and Provincial Health Authorities of North America, April 9, 1938.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Cokato Chiropractor Pleads Guilty to Practicing Without a License

Re State of Minnesota vs. Harold A. Kirsch.

On May 2, 1938, the above defendant, Harold A. Kirsch, thirty-three years of age, entered a plea of guilty to an information charging him with practicing healing without a basic science certificate. Kirsch pleaded guilty at Buffalo, Minnesota, before the Honorable Leonard Keyes, Judge of the District Court for Wright County. After hearing the facts, Judge Keyes sentenced the defendant to pay a fine of $200.00 or serve sixty days in the Minneapolis Work House. The defendant is suffering from multiple sclerosis, and the Court, upon being advised of all the facts, suspended the sentence and placed the defendant on probation upon the condition that he refrain from practicing healing in any manner.

Kirsch, who stated that he was raised at St. Cloud, opened an office at Cokato, Minnesota, in the fall of 1937. He represented himself to the public as a chiropractor and an x-ray technician. He claims to be licensed to practice chiropractic in the State of Iowa, and that he formerly maintained an office at Mason City, Iowa. Following an investigation conducted by the Minnesota State Board of Medical Examiners, a complaint was filed against the defendant on February 1, 1938. Following his arrest Kirsch closed his office. The office has since been reopened by a licensed chiropractor. The defendant undoubtedly deserves considerable sympathy because of his physical condition; nevertheless, he was previously advised that he could not practice in Minnesota without a license, and consequently, when he opened up his office. the Board had no other alternative than to proceed with the case.

Austin Doctor Dies Following Arrest

Re State of Minnesota vs. Fannie Fiester.

On Wednesday, May 4, 1938, the Minnesota State Board of Medical Examiners received a telephone call from Mr. A. B. Anderson, County Attorney of Steele County, informing them that Mr. and Mrs. Anton Ruzek, R. F. D. No. 2, Blooming Prairie, were in his office to make a complaint that a lady doctor at Austin had performed a criminal abortion upon their eighteen year old daughter. The co-operation of the Medical Board was requested in making the investigation and Mr. Brist was assigned to this case.

Following the investigation, which was immediately made, and which included a long signed statement by the daughter, a complaint was filed on May 5, 1938, by the mother, and a warrant issued for the arrest of Dr. Fannie Fiester of Austin. Dr. Fiester was questioned by Mr. Edward T. Helgeson, Sheriff of Steele County, and Mr. Brist, and also by Mr. A. C. Richardson, County Attorney of Mower County. Dr. Fiester admitted having performed the criminal abortion and also admitted performing a number of other unlawful abortions. Dr. Fiester was very frank in her statements, and upon being arraigned in the Municipal Court at Austin, she was released on condition that she furnish a $500.00 bond. The matter was continued until Friday morning, May 6, at which time it was learned that Dr. Fiester was found in a serious condition and died that evening about 10 P.M. Mrs. Ruzek also filed a complaint against Mrs. Clara Cole of Blooming Prairie in connection with this case, and also a complaint against Lyle Cole, twenty-four-year-old son of Mrs. Cole. The complaint against Lyle Cole was filed in Steele County.

This statement is made by the Medical Board in fairness to everyone concerned, and particularly in view of the fact that the case ended in the manner that it did. The Board feels that Mr. Anderson and Mr. Stone, the Assistant County Attorney at Owatonna, Sheriff Helge-

son, Mr. Richardson and Deputy Sheriff Enochson of Austin, were sincerely attempting to perform their duty in respect to this case, and that, while it had a tragic outcome, the entire matter should serve a worthwhile purpose.

Minnesota Physician's License Suspended for Two Years

In the Matter of the Revocation of the License of Harold Rees, M.D.

On May 13, 1938, the Minnesota State Board of Medical Examiners suspended for a period of two years the license to practice medicine held by Dr. Harold Rees of Minneapolis. Dr. Rees' license was suspended because of habitual indulgence in the use of narcotics. His case was called to the attention of the Board by a shortage in his supply of morphine and cocaine discovered by agents of the Bureau of Narcotics.

Dr. Rees is at the State Hospital at Willmar at the present time following his commitment from Hennepin County on April 13, 1938. Dr. Rees has been at Willmar on several previous occasions and the leniency shown him on those occasions accomplished nothing. If Dr. Rees leaves the hospital this time before he is discharged by competent authority his license will be revoked permanently.

Dr. Rees was born in Norway in 1869 and is a graduate of Rush Medical College in 1896. He was licensed in Minnesota by examination in 1900. Dr. Rees has practiced in the following towns in the past ten years: Saint Paul, Cambridge, New London, Ogilvie, Rose Creek, Rushmore and Minneapolis.

Medical Board Revokes Minnesota License of Indiana Physician

In the Matter of the Revocation of the License of George Henry Espenlaub, M.D.

At the regular meeting of the Minnesota State Board of Medical Examiners held on May 13, 1938, the Minnesota license to practice medicine held by Dr. George Henry Espenlaub now serving a one to ten year sentence in the Indiana State Prison at Michigan City, Indiana, was revoked. Dr. Espenlaub, while practicing at Evansville, Indiana, was convicted of a felony, to-wit: assault and battery with intent to commit a felony, to-wit: Rape. Dr. Espenlaub was convicted by a jury and his conviction was upheld by the Supreme Court of Indiana. The record discloses that the crime was committed upon a patient in the office of Dr. Espenlaub.

Dr. Espenlaub was born in Evansville, Indiana, in 1898 and received his M.D. degree from Indiana University in 1922. He was licensed in Minnesota in 1923 by reciprocity with the State of Indiana. However, Dr. Espenlaub did not register with the Minnesota Board in 1928 under the Basic Science law nor has he registered since that date.

POTENCY OF LIVER PRODUCTS

As there is no satisfactory laboratory method which may be used for the standardization of anti-anemia preparations, the Committee of Revision of the Pharmacopeia has provided for an Anti-Anemia Preparations Advisory Board to pass on clinical data which manufacturers of these products might present, and if the data indicated a satisfactory degree of potency, the board would approve the product and it could be labeled under the U.S.P. title. Under the rules of the board the amount of liver supposed to be represented in the product may not be mentioned on the label, as it is likely to be misleading; a product derived from 100 Gm. of liver is not necessarily twice as potent as one made from 50 Gm. Products will now be labeled in units, and patients should receive for a maintenance dosage an average of about a unit each day. (J.A.M.A., March 19, 1938, p. 903.)

OF GENERAL INTEREST

Dr. G. C. Edwards, formerly of Grove City, has opened an office in Cokato.

* * *

Dr. W. R. Kostick, formerly of Robbinsdale, has located in Fertile, where he will practice medicine.

* * *

Dr. and Mrs. E. O. Strassman have moved to Houston, Texas, where Dr. Strassman will practice medicine.

* * *

Dr. John S. Hamlon of Minneapolis has become associated with Dr. R. L. Page of St. Charles, in the practice of medicine.

* * *

Dr. William N. Freeman, Jr., of Perham, Minnesota, was married May 7, 1938, to Miss J'Austa White of Colfax, Washington.

* * *

Dr. A. W. Pasek, who has been practicing medicine at Lismore for the past year, has moved to Cloquet, where he will open offices.

* * *

Dr. E. M. Howg of Lennox, South Dakota, has located at Hills, for the practice of medicine. Dr. Howg was formerly a member of the Mayo Clinic staff.

* * *

Dr. Charlotte Miller of Fargo, North Dakota, is the first woman to finish a year's internship at St. Joseph's Hospital in Saint Paul. She received her diploma early in May.

* * *

Dr. Stella Wilkinson has located at Askov, where she will practice medicine. She is a graduate of the University of Minnesota and has recently been practicing medicine in Duluth.

* * *

Dr. Lyle Joseph Hay of Minneapolis was married on April 16 to Miriam Ilona Raihala, daughter of Dr. and Mrs. John Raihala of Virginia. Dr. Hay is at present an interne at General Hospital in Minneapolis.

* * *

Dr. W. C. Kaufman of Appleton has announced the addition of Dr. Frank E. Lipp on the staff of the Kaufman Hospital. Dr. Lipp was formerly resident physician at Neurological Hospital on Welfare Island, New York City.

* * *

Dr. D. C. Balfour and Dr. J. de J. Pemberton of Rochester attended the meeting of the Society of Clinical Surgery in Chicago, April 29 and 30. Dr. Balfour also attended the meeting of the American Surgical Association in Atlantic City early in May.

* * *

Dr. Ambrose Sprafka has opened an office in St. Cloud for the practice of medicine. Dr. Sprafka is a graduate of the University of Minnesota School of Medicine, and has just completed an internship at the Hospital St. Anthony De Padua in Chicago.

Dr. Dimitri Kalinoff of Stillwater was named to the Stillwater American Legion's Hall of Fame at a banquet held at the Lowell Inn early in May. Dr. Kalinoff was selected for his "unselfish service, without thought of gain" to the community within the past five years.

* * *

Dr. and Mrs. Owen W. Parker of Ely have returned from a recent automobile tour of the southern states, visiting all the Lincoln shrines and many other historic spots. One especially interesting to physicians was the home of Dr. Ephriam McDowell at Danville, Kentucky, where Dr. McDowell performed the first laparotomy in 1809.

* * *

Dr. and Mrs. John S. Lundy of Rochester returned from a three months' European trip, May 27. They toured Italy, Hungary, Germany, Holland, Belgium, France and England. Dr. Lundy was very favorably impressed with the work being done by European physicians as evidenced in the various clinics he attended while there.

* * *

Dr. H. L. Williams of Rochester attended the meeting of the American Laryngological, Rhinological and Otological Society, held in Atlantic City the last week in April, where he appeared on the program, and also attended the meetings of the American Laryngological Association and the American Otological Society, held the following week.

* * *

Dr. H. I. Lillie of Rochester attended the meeting of the American Laryngological, Rhinological and Otological Society held in Atlantic City the last week in April. Dr. Lillie was elected president of the Society at the last meeting. Dr. Lillie also took part in discussions at the meetings of the American Laryngological Association and the American Otological Society, held the first week in May.

* * *

The physicians in the Red Wing territory connected with St. John's Hospital were entertained at a banquet in St. James Hotel dining room on April 19, with members of the hospital board as hosts. The group included over fifty local physicians, and their wives. Dr. Branton of Willmar delivered the principal address of the evening. Dr. L. E. Claydon of Red Wing showed moving pictures taken on his recent trip to Mexico and South America.

* * *

Dr. Theodore Erickson of Montreal, son of Professor and Mrs. T. A. Erickson of Saint Paul, was married May 24 to Miss Mary Rachel Harrower, daughter of Mr. and Mrs. James Harrower of Cheam, Surrey, England. Dr. Erickson is a University of Minnesota graduate and at present is assistant neuro-surgeon at the Montreal Neurological Institute of McGill University. Miss Harrower is a graduate of the University of London and obtained her Ph.D. from Smith College. She has been a research fellow in the Neurological Institute.

HOSPITAL NOTES

The Nagel Hospital at Waconia has recently installed a new deep therapy x-ray unit.

* * *

Dr. Peter Ward, superintendent of the Miller Hospital, Saint Paul, was installed as president of the Minnesota Hospital Association at the close of the association's convention at the Nicollet Hotel, Minneapolis, May 21. Other officers elected were A. G. Stasel, Minneapolis, president-elect; Miss Amy Gunderson, Benson, first vice president; Dr. T. E. Broadie, Saint Paul, second vice president; Roy M. Amberg, Minneapolis, treasurer; and Arthur M. Calvin, Saint Paul, secretary.

New members of the board of directors are Miss Mabel Korsell, Grand Rapids; J. H. Mitchell, Rochester; Miss Esther Wolfe, Minneapolis; Dr. M. J. Hauge, Jr., Clarkfield; and Sister M. Patricia, Duluth.

Dr. A. F. Branton, of Willmar, was named delegate to the American Hospital Association for two years.

Eleven Deaths From a Cancer Treatment

In October, 1935, when the "Ensol" treatment was launched from Kingston, Ont., with what appeared to be carefully planned publicity in the newspapers, *The Journal* issued a warning to the effect that the product was being developed under uncontrolled conditions and that its exploitation would inevitably lead to grief for those concerned. Nevertheless a considerable number of doctors in various parts of the United States have used a product of this type in the treatment of cancer and it is obvious that one at least has come to grief. It seems that the Biochemical Research Foundation of the Franklin Institute of Philadelphia prepared the product called ℞ or Rex, which caused the deaths of 11 patients in Orlando, Fla. It seems likely that batch 152 was prepared on a Friday, some of it permitted to stand over Saturday and Sunday, and then sterilized on Monday. If the tetanus organism was present in the product it would have had two days in which to develop the toxin, so that when the product was sterilized on Monday a sufficient amount of tetanus toxin was present to cause death. These possibilities remain to be confirmed by more evidence—but certainly enough evidence is available to warrant the suggestion. At present there are being exploited to the American people a half dozen or more treatments of cancer that are in no way established as actually of value in the treatment of that condition. Enough is now known about the nature of cancer to indicate that the value of a cancer remedy cannot be established by sending it at random to physicians scattered all over the country, who use it in practice for a fee. The development, exploitation and promotion of "Ensol" and of its progeny "℞" have been unscientific, unethical and unwarranted.—(J.A.M.A., April 9, 1938, p. 1194.)

MINNESOTA STATE MEDICAL ASSOCIATION

Eighty-Fifth Annual Session

June 29, 30 and July 1, 1938

Duluth, Minnesota

OFFICERS AND COMMITTEES

President—J. M. Hayes.....Minneapolis
Past-President—A. W. Adson.....Rochester

ANNOUNCEMENTS

Luncheons.—Two Round Table Discussion Luncheons have been arranged as a special feature of this meeting. The main dining room of the hotel has been reserved for these luncheon meetings. Tickets may be purchased at the time of registration and at the door.

Wednesday.—The luncheon at 12:30 p.m. will be devoted to discussion of Social Hygiene, particularly to lay education on prevention and treatment of venereal disease. W. A. O'Brien, University of Minnesota, will be principal speaker and discussion leader.

Thursday.—The luncheon at 12:30 p.m. will be devoted to discussion of subjects introduced during the Thursday morning session. The morning speakers, including the guest speaker, Dr. Lewin, will be present to answer questions. Dr. O'Brien will be discussion leader.

Friday.—The luncheon period, beginning at 12:30, will be devoted to the first Herman M. Johnson Memorial Lectureship. First lecturer is the Honorable Elmer A. Benson, Governor of the State of Minnesota, and long time friend of Dr. Johnson. J. M. Hayes, president of the Minnesota State Medical Association, will preside and introduce the lecturer. Every member is urged to attend.

* * *

Public Health Meeting.—The public will be invited to attend the Public Health Meeting arranged for Wednesday night at the Orpheum theater, next door to hotel headquarters. Dr. Haggard, famous physiologist and radio speaker, author of the celebrated series "Devils, Drugs and Doctors," and Irvin Abell, Louisville, Ky., president-elect of the American Medical Association, will be the principal speakers.

* * *

The Minnesota Academy of Ophthalmology and Otolaryngology will hold a special dinner meeting at the Kitchi Gammi Club in Duluth on Friday, July 1, in honor of Edward Jackson, of Denver. Dr. Jackson will speak Wednesday at 4 p.m. before the Minnesota State Medical Association and, under the sponsorship of the Academy, he will also give a course of lectures Thursday, Friday and Saturday, June 30, July 1 and 2 on "Practical Aspects of Physiological Optics in Refraction," at St. Mary's Hospital. Registration for this course should be made with F. N. Knapp, 815 Medical Arts Building, Duluth. The fee is $15.

* * *

The Southern Minnesota Medical Association, following its regular annual custom, will present a gold medal to the individual physician who presents the best scientific exhibit at this meeting. Judges will be selected from among distinguished out-of-state visitors. The award will be made at the annual banquet in the Ballroom, Thursday night.

* * *

Annual Banquet.—The annual dinner for members and their wives, which was discontinued for a few years owing to lack of proper facilities, will be resumed again this year. It will be held Thursday at 6:30 p.m. in the Ballroom at the Hotel Duluth. Our celebrated guest speaker, Dr. Haggard of Yale, will be the principal speaker. Dancing in the Ballroom will follow dinner.

* * *

Golf Tournament.—The annual Golf Tournament will begin Saturday morning, July 2, at the Northland Country Club. Registrations for the tournament should be made at the Registration Desk. Entrants will be permitted to organize their own foursomes on a handicap basis. This is the first time the tournament has

been staged at a time when there will be no conflict with other meeting events. Attractive prizes are offered.

VISITING SPEAKERS

Irvin Abell, President-elect of the American Medical Association and Professor of Clinical Surgery at the Medical School of the University of Louisville, Louisville, Kentucky.

Roland S. Cron, Obstetrician and Gynecologist at Columbia and Milwaukee Hospitals, Milwaukee, Wisconsin.

Hollis E. Potter, Head of X-ray Departments of Cook County and Presbyterian Hospitals, Chicago, and former President of the American Roentgen Ray Society and the Chicago Roentgen Ray Society. Sponsored by the Minnesota Radiological Society, Dr. Potter will deliver the annual Russell D. Carman Lecture.

Edward Jackson, Professor Emeritus of Diseases of the Eye, Philadelphia Polyclinic and the University of Colorado, Denver, Colorado.

Philip Lewin, Professor of Orthopedic Surgery, Cook County Graduate School of Medicine, and Attending Orthopedic Surgeon, Cook County and Michael Reese Hospitals, Chicago, Illinois. Sponsored by the Northern Minnesota Medical Association.

Karl Meyer, Medical Superintendent of Cook County Hospital, Chicago, Illinois.

E. K. Marshall, Jr., Professor of Pharmacology and Experimental Therapeutics, The Johns Hopkins University, Baltimore, Maryland. Sponsored by the Minnesota Society of Internal Medicine.

Howard W. Haggard, Associate Professor of Applied Physiology, Sheffield Scientific School, Yale University, New Haven, Connecticut.

C. Anderson Aldrich, Professor of Pediatrics, Northwestern University Medical School, Evanston, Illinois.

BUSINESS PROGRAM

HOTEL DULUTH

Tuesday, June 28

11:30 A.M.—Council ..... Room 118
3:00 P.M.—House of Delegates ..... Ballroom

SCIENTIFIC PROGRAM

Wednesday, June 29, 1938

Chairman: S. R. MAXEINER

Scientific Cinema:
Torek Operation for Cryptorchidism
WALTMAN WALTERS, Rochester

Obstetrical Hemorrhages
R. E. SWANSON, Minneapolis
Discussion: A. K. STRATTE, Pine City

Nutrition in Obstetrics
R. J. MOE, Duluth
Discussion: E. C. HARTLEY, St. Paul

Heart Disease in Pregnancy
J. F. BORG, St. Paul
Discussion: E. M. KASPER, St. Paul

Inflammatory Lesions of the Cervix and Vagina
L. W. BARRY, St. Paul
Discussion: W. F. MERCIL, Crookston

Scientific Cinema:
Congenital Absence of the Vagina—A New Surgical Treatment
V. S. COUNSELLER, Rochester

Carcinoma of the Colon and Rectum
IRVIN ABELL, Louisville, Ky.

Uterine Malignancy
ROLAND S. CRON, Milwaukee, Wis.

Round Table Luncheon:
Social Hygiene
Leader: W. A. O'BRIEN, University of Minnesota

Wednesday Afternoon

Chairman: B. B. SOUSTER

Scientific Cinema:
The Management of—Cancer of the Maxillary Sinus Cancer of the Larynx
LAWRENCE R. BOIES, Minneapolis

Russell D. Carman Memorial Lecture:
The Diagnostic Roentgenology of Adult Pulmonary Tuberculosis with a New Suggestion as to Group Survey
HOLLIS E. POTTER, Chicago. Head, X-ray Departments Cook Co. and Presbyterian Hospitals

The Value of the X-ray in General Practice
C. G. SUTHERLAND, Rochester

Roentgen Therapy in Inflammatory Conditions
T. GAGE CLEMENT, Duluth

Scientific Cinema:
Eye Operations
CHARLES N. SPRATT, Minneapolis

Recognition and Treatment of Refractive Errors in Children
EDWARD JACKSON, Denver

Acute Mastoiditis
J. G. PARSONS, Crookston
Discussion: W. E. CAMP, Minneapolis

Eye Injuries
W. T. WENNER, St. Cloud
Discussion: E. P. BURCH, St. Paul

Wednesday Evening

PUBLIC HEALTH MEETING

Presiding Officer: M. G. GILLESPIE, Duluth
President St. Louis County Medical Society

Greetings
CARL SCHERER, Duluth. President, St. Louis County Tuberculosis and Health Society

Songs by the Normanna Male Chorus

Recent Advances in Medicine and Their Social Significance
HOWARD W. HAGGARD, New Haven, Conn.

Some Aims of the Profession as They Relate to the Public
IRVIN ABELL, Louisville, Ky.

Motion Picture: Emergency Treatment for Fractures

Thursday, June 30, 1938

Chairman: V. S. COUNSELLER

Scientific Cinema:
Os Calcis Fractures—An Improved Treatment
O. W. YOERG, Minneapolis

Fractures: General Principles
CLARENCE JACOBSON, Chisholm
Discussion: E. E. CHRISTENSEN, Winona

Emergency Treatment of Injuries
H. M. LEE, Minneapolis
Discussion: BENJAMIN F. DAVIS, Duluth

Abdominal Injuries
E. MENDELSSOHN JONES, St. Paul
Discussion: W. C. BERNSTEIN, New Richland

Intractable Low Back and Sciatic Pain Due to Protruded Intervertebral Disks: Diagnosis and Treatment
J. G. LOVE, Rochester
Discussion: HAROLD O. PETERSON, Minneapolis

Meeting of March 9, 1938

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, March 9, 1938. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p. m. by the president, Dr. R. T. LaVake.

There were forty-six members present.

Minutes of the February meeting were read and approved.

The scientific program followed.

OPERATIVE DIVISION OF UNILATERAL FUSED KIDNEY*

With Case Report

F. E. B. Foley, M.D.
Saint Paul

Abstract

The case to be reported is that of a unilateral fused kidney.

Brief lantern slide demonstration of the development of the upper urinary tract, at the same time pointing out the fault in normal development that gives rise to the anomaly of unilateral fused kidney, will add interest to description of the condition as clinically encountered. It should also make clear the features of the bilateral pyelo-ureterogram by which the condition is recognized. (Lantern slides.)

Unilateral fused kidney or "tandem kidney" or "crossed dystopia with fusion" is primarily an anomaly of the renal blastemata. It is one of the so-called fusion anomalies. Other anomalies of the same group are "horseshoe kidney" (fusion of lower poles usually, upper poles rarely) and "lump kidney" (conglomerate fusion). In unilateral fused kidney there is fusion between the lower pole of one kidney and the upper pole of the second kidney. The fused kidneys both lie to one side of the midline. Thus one kidney is ectopic across the midline. Almost regularly the lower kidney is the ectopic one and the fusion is at its upper pole. The ureter of the ectopic kidney crosses the midline to enter the bladder in normal position. Rarely the upper one of the two kidneys is the ectopic one. Only a few cases of this latter relationship have been reported.

The permanent kidney is formed from two elements. The ureteral bud arising from the Wolffian duct forms the excretory channels including almost the whole length of the tubules, papillary ducts, minor calyces, major calyces, pelvis and ureter. By branching growth the ureteral bud extends into and is covered by the renal blastema. The renal blastemata or nephrogenic cords are masses of mesodermal cells lying dorsal to the Wolffian ducts, one on each side, and entirely separate from the Wolffian ducts. From the renal blastema are developed the glomeruli and short connecting tubes that unite with the tubules formed from the ureteral bud.

At beginning formation of the permanent kidneys the two caudally placed renal blastemata lie close to each other but normally are completely separate. So far as I know it has not been determined just how and when fusion occurs, whether it is a primary fault in the formation of the blastemata, and present before the migration of the kidneys begins, or occurs during migration, particularly as the kidneys approach each other in passing through the narrow ring formed by the umbilical arteries.

Normally the migration of the kidney has three components of motion: ascent, rotation and axial deflection.

1. *Ascent.*—Normally the kidneys ascend to positions well up in the lumbar regions—the renal fossæ. When all possible ascent of the unilateral fused kidney has occurred its elongated form leaves its lower segment in abnormally low position. In addition the lower segment is drawn across the midline by the upper segment.

2. *Rotation.*—Normally the kidney rotates on its long axis so that the hilum, originally directed ventrally, is finally directed medially with the calyces extending laterally from the pelvis. Fusion of the two organs impairs this rotation particularly at the fused poles. In consequence some of the calyces of the unilateral fused kidney extend medially from the pelvis.

3. *Axial Deflection.*—Normally the long axis of the kidney, at first oblique toward the midline below, is deflected during migration to become oblique toward the midline above with the upper pole lying closer to the midline than the lower pole. Fusion of the two organs interferes with this normal axial deflection. In consequence, the long axis of the upper segment of the unilateral fused kidney remains oblique toward the midline below, the lateral movement of the lower pole being arrested by the fusion.

Because of these faults in development the "bilateral" pyelogram of a unilateral fused kidney with crossed ectopia of the lower segment representing the left kidney will show an upper (right) pelvis perhaps normally high in the renal fossa with its long axis oblique toward the midline below and its inferior calyces extending medially from the pelvis. The lower (left) pelvis will be abnormally low-lying, its axis extending obliquely downward from the lower pole of the upper (right) pelvis and even reaching somewhat across the midline while its ureter, crossing the midline, terminates in normal position in the left side of the bladder.

Case Report

The case to be reported is that of an unmarried woman, aged eighteen (Ancker Hospital record No. A-73402.)

*Dr. Foley gave a motion picture demonstration of the operation.

The complaint was of left sided abdominal pain which had been present in variable degrees during the three years prior to her first admission to the hospital in August, 1936. At first the pain occurred in attacks. It was very severe, located in the left upper quadrant, appeared to be induced by exercise or other activity and to be relieved by lying down. At times the pain extended to the left lower thorax and to the left upper quadrant of the abdomen. Later constipation accompanying the attacks was noted. Weight loss of 15 pounds occurred.

Following almost complete relief of symptoms for a period of eight months the patient was admitted to the hospital for the third time, June 4, 1937. On this occasion there had been an attack of severe pain in the left lower quadrant followed by frequent periodic recurrences and finally by constant and persistent dull aching pain in this location. She was transferred to the urologic service.

The significant findings of the physical examination and laboratory investigations were: a rounded somewhat elongated mass lying below the umbilicus with its long axis extending longitudinally. The mass was slightly moveable in longitudinal direction and was tender to pressure. The mass transmitted the aortic pulsation but did not expand with it. On percussion, bowel tympany was present over the mass. The urine was normal, hemoglobin 57 per cent, leukocytes 3,600 per cu. mm., blood urea nitrogen 13.3 mgms. per 100 c.c. Excretion urogram: nearly normal function of each kidney; indefinite outlining of pelves and ureters with deformity typical of unilateral fused kidney with crossed ectopia of the left and lower segment. Cystoscopy: normal bladder mucosa and contour; ureteral orifices normal position and normal appearance. Indigo-carmine test of renal function: right—appearance time four minutes, deep concentration; left—appearance time seven minutes, moderate concentration. Bilateral pyelogram: clear outlining of deformity typical of unilateral fused kidney with crossed ectopia of the left and lower segment, no dilatation of the right pelvis or calyces, grade I dilatation of the left pelvis and calyces. Filling of the pelvis of the left segment produced pain identical with the pain complained of both as to character and location.

Diagnosis and summary of findings: Unilateral fused kidney with crossed ectopia of left and lower segment not accompanied by any significant pathologic change apart from the anomaly and responsible for painful symptoms.

Therapeutic indication: Operative division of the renal isthmus and correction of renal malposition.

A color motion picture film of the operation will now be shown. The malformed kidney was exposed through an extra-peritoneal right flank incision. The isthmus was divided between two rows of mattress sutures. The left kidney was displaced to the left and its upper pole was held medial to the vena cava by suturing the posterior parietal peritoneum to the posterior abdominal wall along the right border of the cava, the right kidney was fixed in normal position by the Foley nephropexy (Arch. Surg., 1929).

The result to date, ten months after operation, is excellent, there being complete relief of the pain complained of before operation. A bilateral pyelogram made two months following operation showed the right kidney and pelvis in normal position and of normal appearance and the position of the left pelvis somewhat improved.

At the time this operation was performed a cursory review of the literature disclosed no other case of division of the isthmus of the unilateral fused kidney without removal of one or the other half. Since then further search has disclosed a total of fifty-one cases of operation on the unilateral fused kidney, most of them undertaken for concomitant pathologic change such as stone, hydronephrosis, etc. However, among the fifty-one cases, four cases of operation similar to that here reported were found.

In addition to this case of operative division of the isthmus of the unilateral fused kidney, we have performed the same operation in six cases of horseshoe kidney with equally satisfactory results in all save one case in which an unremoved stone and persisting infection made secondary nephrectomy necessary on one side.

It is submitted that unilateral fused kidney or horseshoe kidney causing only painful symptoms and not accompanied by pathologic change apart from the anomaly should be the object of surgical interference of the sort described here.

Discussion

Dr. W. F. Braasch, Rochester: I am compelled to say a few words of commendation and praise for the excellent presentation made by Dr. Foley and the unusual operation that he described. I remember that I discussed his paper on the separation of the isthmus with renal fusion four years ago and at that time I praised him for his originality; and now I again do so.

We urologists used to think that we were quite clever to make the clinical diagnosis of fused kidney prior to operation. Today it is getting to be an old story. Patients now come in frequently with the diagnosis already made by the local physician, by means of excretory urography. By employing this simple method of diagnosis it is no longer difficult to recognize renal fusion. On reviewing our records at the Clinic the other day, I found that during the past year a diagnosis of renal fusion was made in thirty-two cases. In a paper written by Judd, Scholl and myself some sixteen years ago, we described sixteen cases of renal fusion which had been operated on at the Mayo Clinic. One case among those reported (case No. 3) was operated on by Dr. C. H. Mayo in 1917, in which he made the first symphysiotomy for horseshoe kidney reported in this country. Rovsing first described this operation in 1910 and Papin later improved the operative technic. As far as I know, division of a unilateral fused kidney has not been done at the Clinic. We have operated on unilateral fused kidneys for such complications as stone and hydronephrosis, but have not bisected the kidney as Dr. Foley has described. Not all kidneys with unilateral renal fusion can be divided. In some cases the two renal pelves will be so closely related and the kidney assume such a shape that renal division will not be technically possible, or at least will offer considerable difficulty.

It should be remembered that there are difficulties in deciding whether a fused kidney should be operated. In many of our cases diagnosed clinically, we found no indication for operation. Apparent pyelectasis of moderate degree is often observed in the urogram with renal fusion, which has caused no symptoms. Although the pyelectasis in some cases is extensive, the patient has not complained of any pain. It may be difficult to determine whether actual stasis and obstruction are present. Patients also are observed who complain of pain but fail to show pyelectasis in the urogram. It can be very difficult to decide whether the apparent pyelectasis is the cause of the patient's symptoms. Of two cases in which the isthmus was

resected and the kidneys displaced, the pain persisted in one. In the other case the pain was relieved for several months and then returned. It should be remembered, before advising surgery, that many patients with renal fusion have no symptoms caused by the anomaly, which is discovered accidentally in the course of routine urography.

In closing, I wish to repeat that the operation Dr. Foley describes is a very interesting one and I congratulate him on the result obtained.

Dr. F. R. Wright, Minneapolis: It is always an interesting proposition to me why a patient will go on for forty or more years with an anatomical anomaly and then begin to develop symptoms. For instance, what change took place in this girl of 18 years that brought about the painful symptoms? She had had this condition all her life. Something had taken place which produced physiologic pain.

Dr. Foley (in closing): It is always a pleasure to receive Dr. Braasch's compliments and have him make an interesting and instructive discussion of this sort. With the wealth of material that has gone through his hands, close attention must be paid to his views.

I did not intend to indicate by any means that every case of renal fusion encountered should be the object of surgical interference. There are many cases in which there is no associated pathologic change and pain is either absent or cannot be shown to be caused by the anomalous renal formation. Such cases provide no indication for surgical interference. As Dr. Braasch points out, it may be difficult to determine if there are adequate indications for operation. In this case of unilateral fused kidney and in the six cases of horseshoe kidney mentioned, pain of renal origin was present in all. In the present case and in five of the horseshoe kidney cases, division of the isthmus and nephropexy has given excellent results with complete relief of pain. I do not claim that the result in the case here reported is an eventual end-result, as only ten months have elapsed since operation. However, up to the time of the last report, three days ago, complete relief was still present.

Dr. Wright brings up a very interesting question. Why congenital renal anomalies remain symptomless for years and then suddenly cause pain I do not know. Dr. William Quinby, a competent observer, points out the very interesting fact that pain occasioned by anomalous renal vessels very frequently begins at the time full development is reached. Onset of pain at this same period of development is frequently observed with the other more extensive renal anomalies. It will be noted that in the present case the painful symptoms began at the age of fifteen, approximately the time that full development obtains in the female.

MALIGNANT HYPERTENSION

Report of Two Cases

Hendrie Grant, M.D.
Saint Paul

Dr. Grant, of Saint Paul, reported two cases as follows:

Case 1.—Mrs. W. S., widow, aged fifty-nine, first came for examination on December 16, 1937, complaining of poor vision which had begun approximately a week before. There was also an associated asthenia and vertigo. Previous history shows that fifteen years ago there was a sudden loss of vision in both eyes, which condition was treated by the late Dr. deSchweinitz of Philadelphia and at that time there were diffuse retinal hemorrhages and a blood pressure of over 200 systolic. After a period of rest in bed of two months, the vision cleared up and became quite satisfactory again. There has been no visual difficulty from that time until the present, when on examination the vision was: Right 20/200, Left 20/50. Fundus examination at this time showed some lens and vitreous haze, diffuse retinal edema with marked arteriolar spasm, thickening of the larger arterioles, arteriovenous compression and an edema of one diopter of each optic nerve. There were hemorrhages and cotton-wool patches in the right macular area.

General examination revealed marked arthritic changes in the hands and knees. Heart enlarged about 50 per cent with a widened base and marked sclerosis of the peripheral vessels. There was a slight trace of albumin, a few red blood cells and hyaline casts present in the urine.

After a period of rest in bed for two months there was a marked improvement in the vision of the left eye, although the blood pressure was still 180 systolic and 110 diastolic.

Comment.—Following a rather severe angiospastic retinitis with systolic pressure of 200, there was a complete remission for a period of fifteen years. Although such remissions are not uncommon, and sometimes occur even in cases of malignant hypertension, the picture now present is undoubtedly one of a more serious condition. The arterial and arteriolar thickening, visual disturbances, arteriolar spasm and some demonstrable swelling of the optic nerves are characteristic of the condition present. Marked improvement which resulted from rest in bed, sedatives, and some reduction in the pressure itself, are the indications of a fair prognosis of this condition.

Case 2.—Mr. J. J., aged forty-three, first came for examination on December 28, 1937, complaining of loss of vision in the left eye for the past few weeks. There had been some difficulty with vision since early in the Spring and it was becoming increasingly difficult to work. Hypertension had been present for the last five years and in June was associated with anorexia, fatigue, vomiting and diffuse abdominal pain. There was a weight loss of 15 pounds. He was in the hospital for a short period in June recovering from an attack of bronchitis.

On examination the vision was: Right 20/20, Left 20/200. Fundus examination revealed that the right optic nerve showed three diopters of swelling with marked arteriolar spasms and hemorrhages around the disk. The larger vessels showed a thickening and arteriovenous compression. In the left eye only a moderate swelling of the disk was present without hemorrhages or exudate. Visual fields showed a contraction of the right with nasal hemianopia of he left eye. The blood pressure was 250 systolic over 150 diastolic. The urine showed a trace of albumin and occasional red blood cells. Kidney function was 57 per cent. After a period of rest in the hospital with the usual sedatives and spinal puncture, there was a slow but steady rise in the pressure to 260 systolic, 160 diastolic. Headaches became more severe and cotton-wool exudates appeared in the right eye.

Comment.—Hypertension, which had existed for several years, was accompanied a few months before examination by definite symptoms of general weakness with evidences of arteriolar spasm. There was no improvement whatever following glucose and sucrose intravenously and a definite increase in blood pressure seemed to follow spinal fluid drainage. All of these measures are oftentimes sufficient to produce a remis-

sion of this condition, but at times the angiospastic feature of the condition is so pronounced that there is a sudden failure of the brain, heart or kidneys. It is difficult to explain the field changes or the hypertensive or fundus findings.

Discussion

Dr. W. E. Camp, Minneapolis: Dr. Grant has very thoroughly and very instructively presented these two cases of malignant hypertension. With his permission, I would like to show a few lantern slides completing the ophthalmoscopic picture in these types of cases and correlating these findings with the microscopic pathologic change which is usually present. These slides were made from serial sections of the eye of a case of malignant hypertension, which died a renal death. According to Dr. E. T. Bell, about 5 per cent of all cases of malignant hypertension die a renal death. The slides show a marked edema of the optic nerve and the surrounding retina with a small flat detachment of the retina on either side of the optic nerve. The marked sclerosis of the retinal and choroidal arterioles is well demonstrated. The thickening is chiefly in the intima and media and consists of fibrosis and hyaline deposits. The cotton-wool exudate in the superficial layers of the retina is found to be due to edema and serum deposits containing a few large phagocytes or macrophages. The "star-shaped" figure in the macular region is due to lipoid exudate in the deeper layers of the retina. These exudates with the ophthalmoscope appear as small, yellowish-white, highly refractile bodies and form an incomplete "star" in the macular region. Fat stains show that they are lipoids in character and when once formed are more permanent than the soft cotton-wool patches described above. All of the above-described features compose the picture of the retinitis found in malignant hypertension.

Dr. Moses Barron, Minneapolis: Dr. Grant's cases are interesting both from the point of view of the oculist and of the internist. It is rather unfortunate that the terminology is often confusing. The oculist's diagnosis of malignant hypertension usually applies to those cases in which there is hypertension and which develop retinal changes such as edema, narrowing of the arterioles, hemorrhages, edema of the disc, as described by Dr. Grant. The internist, on the other hand, generally uses the term to designate the type of case represented by Dr. Grant's second case, and the one illustrated by Dr. Camp; that is, malignant hypertension is meant to describe a case of essential hypertension which develops renal changes with renal insufficiency which usually results in death from uremia. Very commonly the characteristic retinitis picture is present. Dr. Camp mentioned that about 5 per cent of these cases die of uremia. From our point of view, about 95 per cent of these cases die of uremia. The renal changes are often characteristic. In a paper that was delivered before this Academy a year ago, I tried to point out the characteristic changes in the kidneys. The changes are degenerative; very pronounced are the changes in the arterioles with arteriolar necrosis. Dr. Grant's first case would be considered a case of essential hypertension with angiospastic involvement. Such cases often respond well to spinal drainage. His second case, in which the patient is progressively going down hill and in which there developed symptoms of uremia, is a typical case of malignant hypertension. Such cases do not respond very well to spinal drainage. I wonder if Dr. Grant would tell us on what basis he uses the term malignant hypertension.

Dr. Grant (in closing): I think that, for the purpose of differentiation, we have three types of hypertension: (1) essential hypertension, with no signs except organic changes in the vessels; (2) the acute vasospastic disease which one sees in pregnancy and occasionally in acute infections, in which there is sudden loss of vision accompanied by swelling of the disc, cotton-wool exudate and hemorrhages of the retina; these signs have been known to disappear even in instances when the condition is dependent upon an acute infection; and (3) malignant hypertension, in which the patient presents such general disturbances as asthenia, fatigue, or neurological signs associated with organic vascular changes, hemorrhages and exudate into the retina, arteriolar spasm and a demonstrable swelling of the optic nerve.

Approximately 80 per cent of cases of malignant hypertension live less than one year. There are several cases reported in which remissions lasting four and one-half years have been present. Dr. Wagener has recently reported six cases which have had prolonged remissions after the diagnosis was made. Many cases of malignant hypertension have microscopic or gross evidences of hematuria. In some instances there may be a very rapid degeneration, the individual living only a little more than a week.

The meeting adjourned.

A. G. Schultze, M.D., *Secretary.*

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PEDIATRIC NURSING. By John Zahorsky. 568 pp. $3.00. St. Louis, Mo.: C. V. Mosby Co., 1936.

It would seem that texts for nurses, if compiled by physicians, tend to become abbreviations of like volumes for physicians. More attention to nursing technic would seem indicated, inasmuch as this is of particularly specialized nature in relation to pediatrics. In general this volume seems but little different from many others of its kind, and gives in brief form a discussion of the more common child ailments.

Thomas Myers, M.D.

EXAMINATION OF THE PATIENT AND SYMPtomatic diagnosis. John Watts Murray. 2nd ed. $10.00. 1219 pps. St. Louis: Mosby, 1936.

This is a large and detailed monograph on physical diagnosis, which should be very useful in looking up any group of symptoms.

It is divided into two sections: Section 1 giving the details of history-taking, covering all parts of the body and calling attention to the symptoms to be looked for and listing the causes for such symptoms; Section 2 considering the various systems or sections of the body and the disorders to which they are liable.

Numerous illustrations and diagrams add to its usefulness. The index is fair, but the table of contents is very full and between the two one can find any symptom. The book's completeness and form make it valuable for reference and not for general reading.

E. E. Scott, M.D.

MINNEAPOLIS SURGICAL SOCIETY

Stated Meeting, Thursday, April 7, 1938

MESENTERIC CYST

Case Report

W. C. Peterson, M.D.

The first case of mesenteric cyst was observed in 1507 by Benevieni, a Florentine anatomist, who accidentally found such a cyst at autopsy and classified it as an anatomical curiosity. In 1880 Tillaux successfully operated on a cystic mesenteric tumor.

Mesenteric tumors are the rarest tumors in the abdomen but cystic tumors are four times as common as the solid neoplasms.

In a very complete article and bibliography by Dr. J. Ogle Warfield, Jr., from which I have very lavishly drawn my information, it is stated that probably 500 cases have been reported in the literature up to 1932.

Briefly, mesenteric cysts may be classified according to origin as follows:

1. Embryonic retroperitoneal organs, such as germinal epithelium, ovary, wolffian or müllerian bodies.
2. Displaced embryonal intestinal tissue.
3. Dermal inclusions.
4. Angiomas of blood and lymph vessels.
5. Parasitic and bacterial infection.
6. Necrosis of lymph glands or solid tumors.
7. Trauma and foreign bodies.

Mesenteric cysts occur most commonly in the fourth decade and women are affected twice as often as men.

Diagnosis.—There are no pathognomonic signs or symptoms of mesentric cyst. However, an abdominal tumor which is rounded, cystic, mobile and not tender, should suggest such a cyst. The mobility is the outstanding sign. These cysts are located most commonly in the mesentery of the ileum and next most frequently in the jejunum, cecum, ascending and transverse colon.

Pathology.—These cysts may be so small as to be unrecognized, or so large they fill the entire abdomen. The cyst wall is usually composed of fibrous or elastic tissue with the lining so compressed that its cellular structure cannot be identified. Only occasionally is some tissue present which will identify the origin of the neoplasm. Malignancy is rare.

Complications.—Intestinal obstruction is the most common complication, occurs in one-third of the cases and of these the mortality is 50 per cent. Peritonitis, hemorrhage into the cyst, rupture into the bowel, torsion and impaction have all been reported.

Treatment.—1. Enucleation is the operation of choice and has the lowest mortality, 9 per cent.

2. Enucleation with intestinal resection, 16.6 per cent.

3. Drainage or marsupialization has been done in some cases.

4. Aspiration.

Report of Case

A white spinster, seventy-five years of age, was seen October 4, 1937. Her past history was entirely irrelevant.

The patient had noticed a swelling in the abdomen for about three years. It was entirely painless and only troubled her by being in the way in adjusting her clothing.

Examination showed a very well preserved elderly woman, with normal findings except for a rounded protruding abdominal mass, not unlike a seven months pregnancy in a sparely nourished woman. The mass was not tender and was very freely movable.

Vaginal examination showed a small uterus.

Diagnosis: Large pedunculated ovarian cyst or fibroid.

Operation: A midline incision was made and on examination the tumor was readily seen to be in the transverse mesocolon. The posterior layer was incised and the cyst was dissected out quite readily except near the transverse colon. The thin areas in the colon were plicated, the rent in the mesentery closed and the abdomen sutured. The cyst was thin walled, weighed 2125 grams, was 15 cm. in diameter, and contained over 2 litres of bloody fluid.

Recovery was uneventful.

Discussion

Dr. Martin Nordland showed slides demonstrating a case of mesenteric cyst. The case was previously reported before this Society.

Dr. J. F. Corbett: I have a case perhaps worth reporting from the standpoint of its unusual location. Like the essayist, I did not make a diagnosis beforehand. The tumor in this case I could feel but it did not seem to me at all movable. I expected to find something connected with either the tube or the ovary. When I opened the abdomen I found a cyst between the layers of the sigmoid at a very low level, practically where the mesentery comes down. I then recognized I was dealing with a cyst, thin-walled, and probably two or two and one-half inches in diameter.

In getting this out I found that because of the anatomical location the cyst had pushed its way somewhat into the bowel, leaving a paper thin mucosa only, so much so that I was afraid to close it without resecting the bowel. I therefore took out a complete segment of bowel and succeeded in making an end-to-end anastomosis. The pathologist reported a thin-walled cyst, undoubtedly embryonic in origin.

RECTO-URETHRO-VESICAL FISTULA, TRAUMATIC

Case Report

Robert F. McGandy, M.D.

The case I wish to report is that of a laborer, thirty-three years of age, whom I first saw in a rural hospital in Wisconsin, on September 26, 1932. He gave a history of slipping, falling backwards six feet, striking on a bolt which protruded eleven inches from a log. The bolt entered his perineum behind the rectum and went into the rectum in a somewhat sweeping fashion, penetrating the prostatic urethra and bladder. He bled considerably and was taken immediately to the hospital where he was seen by a doctor from a neighboring town. He was taken immediately

to the operating room where the doctor's examination revealed a large tear in the perineum, a three-inch tear in the posterior wall of the rectum and a six-inch tear in the anterior wall of the rectum. The doctor stated he could put his hand into the wound and noticed that the prostatic urethra had been torn for a distance of about one inch and a considerable amount of prostatic tissue had been torn away. The wound entered the bladder and urine could be seen coming out of it. The doctor attempted immediate repair of the rectum and let the rest of the wound fall together. That night, when the regular doctor at the hospital returned, the accident having happened at 8:40 in the morning, it was noticed that the patient was unable to void. The doctor was unable to pass a catheter and for this reason opened the bladder suprapubically and was able with difficulty to institute drainage through the urethra. He also left a drain in the suprapubic opening. The patient's temperature had been 102 for several days and his leukocyte count was 13,200. When I saw him, his temperature was between 99 and 100. The doctor had been irrigating the bladder daily. Urine was coming from the abdomen and urethra as well as the rectum. The patient was very restless, in extreme pain, markedly dehydrated and very toxic. An examination revealed a large three-inch long, foul smelling, pus discharging wound in the perineum and rectum. There was a tube inserted in the rectum and the stitches had sloughed away. As the patient could not be moved, I suggested more fluids, sedatives and hot packs to the perineum, in addition to what the doctor was already doing.

I saw the patient at the same hospital again on October 10, 1932. For the past five days the patient had had a high temperature and was suffering from a respiratory infection which proved to be pneumonia. He was still toxic and had a Vincent's infection in his mouth. Urine was coming from the abdomen and perineal wound. The urethra was not draining and the patient had a definite urethritis and epididymitis. Abscesses had formed in the shaft of the penis and drained pus. I felt the rectal wound had improved somewhat although the margins were angry. I could put my index finger in the rectal canal. I adjusted the catheter in the urethra and drainage was obtained through it. The blood chemistry was normal but the patient was becoming irrational at times. Definite suicidal tendencies had been noticed. The doctor stated that the patient had had voluntary stools. The urinary infection was apparently responding somewhat.

On November 17, 1932, this patient was transferred to the Northwestern Hospital in Minneapolis by ambulance. His temperature was 99 on admission and the patient presented the picture of exhaustion. He was discouraged and depressed. The nurse who came with him repeated the fact that he had many suicidal tendencies. He had a considerable amount of pain in his penis and perineum and he was poorly nourished. Urine drained suprapubically, through the catheter in the urethra as well as through the rectum. Urinalysis revealed a large amount of albumin with 50 to 75 pus cells per high powered field. There were two or three red blood cells per high powered field and many granular and hyaline casts. Wassermann reaction was reported to be negative. Hemoglobin was 74 per cent; red cells, 4,110,000; leukocytes, 16,500; non-protein nitrogen, 22.4 mgms. per 100 c.c.; creatinine, 1.2 mgms. per 100 c.c.

The patient was placed on regular bladder irrigations and urinary antiseptics. The urethral catheter was frequently changed and when out the fistulæ in the shaft of the penis drained. He was also given hot packs to his genitals and perineum. Fluids were forced and although sedatives were given, little success resulted from them. The patient had frequent suicidal tendencies in the hospital and had to be watched constantly. The condition of his perineum and bladder gradually improved. On November 28, with the aid of a rectal speculum, I was able to pass a rubber catheter into the fistula opening in the rectum up to the bladder. I repeated this procedure on November 30 and injected some silver iodide emulsion obtaining an x-ray picture demonstrating a fistulous tract into the bladder.

Irrigation and urinary antiseptics were continued until December 8 when this patient was taken to the operating room, where under general anesthesia a perineal racket-shapped incision was made. As was to be expected, a considerable amount of scar tissue had formed both in front and behind the rectum. The rectum was dissected with difficulty from the surrounding structures after the method used in the oid Whitehead operation for hemorrhoids. The dissection was carried upwards to a point about two centimeters above the entrance of the fistulous tract into the rectum. I could readily pass two fingers into the sinus opening, which led from the rectum up to the region of the posterior urethra and bladder. The fistulous tract was used to close the opening in the bladder and posterior urethra. This was reinforced with what remained of the prostatic capsule. It was thought best to sacrifice the rectum below the sinus opening. A new rectum was therefor pulled down in the manner used in the Whitehead operation. The sphincter musculature was markedly atrophied, retracted and composed of a considerable amount of scar tissue. However, what remained was approximated as best possible. The wound was drained. Fresh catheters were placed in the suprapubic and urethral channels.

The patient was placed on a low residue diet and sedatives. He was given subcutaneous fluids and definite steps were taken to prevent him from having a bowel movement. His temperature went up to 101 for the first three days. On December 10, two days after the operation, the patient became irrational and remained so until the 16th of December. He had to be placed in a straight jacket on December 12. Five days after the operation, he had a bowel movement consisting mainly of old blood. His thrashing around in restraints opened the perineal wound slightly. He was seen on December 15 by Dr. Hamilton, who felt we were dealing with an acute toxic delirium which apparently started originally after his pneumonia. It subsided with hallucinations and suicidal tendencies running along, only to become acute again following his present operation. The restraints were removed, however, on the 17th of December, and the patient progressed quite well. I removed the suprapubic drain as soon as he became rational and on the 27th of December, I removed the catheter from his urethra. As I stated above he had several fistulæ in his penis, one being at the scroto-perineal angle. When the catheter was removed from the urethra, urine drained from these fistulous tracts, but many of the fistulæ in the shaft closed spontaneously. The rectal and suprapubic wounds closed normally and the patient was discharged from the hospital on January 18, 1933.

I did not see the patient again until February 7, 1933, when he returned from the country. He had gained ten pounds and his general condition, including his mental state, had improved remarkably. His complaints were that he noticed difficulty controlling his rectal sphincters during an attack of acute diarrhea from food poisoning. He also complained of dribbling of urine at the beginning and end of urination and the fact that he drained urine from a sinus opening at the junction of the perineum and scrotum. The suprapubic and perineal wounds had closed satisfactorily. I could put my index finger readily into his rectum. Because of the possibility of the opening tightening further I furnished him with some rectal dilators which he used regularly. I also began to dilate his urethra in the hopes that by so doing the fistula at the scroto-perineal angle would close spontaneously. Dilatations, however, were usually followed by attacks of epididymitis, one of which necessitated surgical drainage.

I, therefor, at a later date ligated the vas deferens on both sides and continued dilatation more vigorously. I was finally able to use a 28 French sound but the sinus persisted. For this reason, I placed the patient in the hospital again and on November 15, 1933, repaired the sinus at the scroto-perineal angle. The tract was 1.5 inches long but was not difficult to repair. I used an indwelling catheter in the urethra for four days. The wound healed satisfactorily. I saw this patient a few months ago and he is doing very well and is working every day. He has no difficulty if he keeps his stools soft and does not allow his bladder to become over-distended before voiding.

IMPALEMENT OF THE RECTUM

With Report of Two Cases of Injury to the Bladder

Gilbert Cottam, M.D.

Impalement of the rectum was used by the ancient as a form of punishment. The oldest collection of laws in the world, the Code Hammurabi (*circa* 2200 B.C.) contained specific allusion to it in the following words, as translated, in 1903, by C. W. Johns: "If a man's wife on account of another male has caused her husband to be killed, that woman upon a stake one shall set her." Pennington (A Treatise on the Diseases and Injuries of the Rectum, Anus and Pelvic Colon, 1923) mentions that in ancient Rome impalement was at first restricted to slaves who had been guilty of robbery and that later on, Nero resorted to it among other measures in his persecutions of the Christians. The Ottoman Turks used it soon after their irruption into Europe, for various offenses. In the Middle Ages it was used in Russia, Germany and Austria in cases of murder and witchcraft. It is said to have been used in the Inquisition. One of the English kings, Edward II, was murdered (A.D. 1327) in Berkeley Castle by having a red-hot skewer thrust up his rectum through a cow's horn used as an obturator. Pennington, on the authority of Fairlie, states that a form of impalement is in vogue today in the Malay Peninsula as punishment for female marital infidelity. A species of bamboo which grows with extraordinary rapidity, 24 inches in 24 hours, is used and the condemned woman is lashed to stakes over this bamboo, causing impalement in two days.

Accidental impalement of the rectum as it occurs in modern life is not a very uncommon injury. It happens in a wide variety of circumstances and with greatly differing vulnerating agents, but probably the most frequently encountered type is that which takes place in agricultural communities, in the manner about to be described. Those who are interested in the other types will find detailed information in the papers of Weller Van Hook, of Chicago, whose article entitled "Rupture of the Rectum by Penetrating Bodies," with description of 58 cases collected from the literature, with one of his own included, published in *Medicine* for June, 1896, was the first contribution of the kind of any comprehensive importance to literature; of Herman Tillmans, who described 143 cases (including the vaginal type) in his article "Die Verletzungen u. Chir. Krankheiten d. Beckens," in *Deutsche Chirurgie,* 1905, Heft 62A; and finally in that of Otto W. Madelung, of Charlottenburg, entitled: "Die Pfählungsverletzungen des Afters un des Mastdarms" in *Arch. f. klin. Chir.,* 137:1-80, 1925, which contains an enormous bibliography covering eight and a half pages of closely printed references from all over the world. While, as the titles indicate, these two German articles just referred to deal with all kinds of wounds of the rectum and anus, a considerable number of impalements will be found to be described therein and some of these are of a nature to tax credulity, if it were not that they are fully authenticated by reliable observers.

Tonight our attention will be concentrated on the variety which occurs commonly in farming conditions and in a manner so uniformly similar that one description of the way in which it takes place will fit practically all cases. A farmer riding on top of a load of hay throws a pitchfork to the ground and slides down. The tines of the pitchfork have stuck in the ground and the handle stays up; the man straddles this handle and the point strikes his perineal region and is directed into the anus, in the manner described by Van Hook. One of five things is then obliged to happen: (1) The handle may merely enter the lumen of the lower bowel and do no more harm than cause contusions, abrasions and tears of the mucous membrane and sphincters; (2) it may penetrate the wall of the rectum anteriorly and damage the tissues of the recto-vesical septum, without injuring the bladder or entering the peritoneal cavity; (3) it may penetrate the anterior wall of the rectum and injure the bladder, without entering the peritoneal cavity, as in the first case I shall describe tonight; (4) it may penetrate the anterior wall of the rectum, traverse the recto-vesical septum, enter the bladder from behind and reach the peritoneal cavity through the top of the bladder, as in my own case, the second to be described tonight, or (5) it may penetrate the anterior wall of the rectum high enough to miss the bladder and reach the peritoneal cavity direct.

The immediate effects of an injury like this, no matter how extensively the parts involved are damaged, are often surprisingly slight. There is usually very little bleeding, no shock and a minimum of pain. In some of the cases reported the patient has removed the vulnerating agent himself and walked some distance afterwards. In a case reported by G. D. Whyte in the *Edinburgh Medical Journal* of March, 1911, page 255, a Chinaman had a piece of bamboo 8 inches long and 1.5 inches in diameter pushed up his rectum. He pursued his assailants for some distance, the piece of bamboo meanwhile working up into his lower bowel so that on admission the lower end could easily be felt in the iliac region, while the upper one passed under the rib margin where it could not be defined. This initial freedom from pain, shock, et cetera, is very misleading. Lay people do not appreciate the gravity of the situation and many doctors are slow to recommend intervention until peritonitis is well on the way and the chances of recovery even with operation are greatly diminished. Consequently, the super-

stition has arisen that these cases are better left alone and not operated upon.

This undoubtedly does apply to the non-penetrating cases, that is, those in which the vulnerating agent does not enter the peritoneal cavity, for most of these do

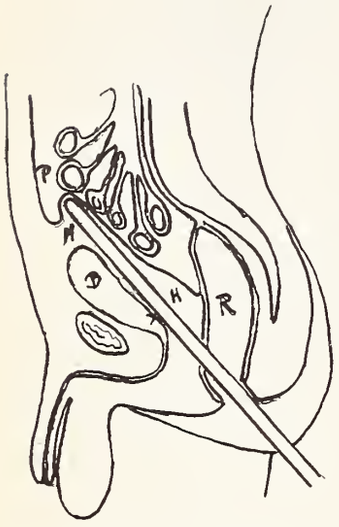

Fig. 1. *(left)* Dr. W. E. Morse's case. *P,* peritoneal cavity; *H,* hematoma; *B,* bladder; *X,* site of injury to bladder; *R,* rectum.

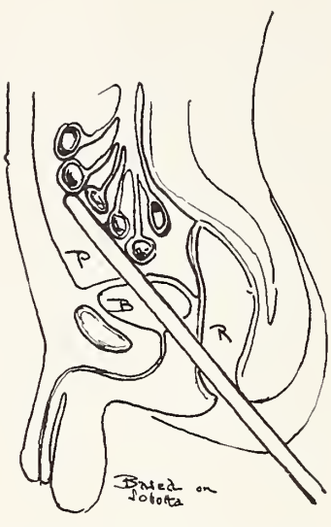

Fig. 2. *(right)* Author's case. *P,* peritoneal cavity; *B,* bladder; *R,* rectum.

recover under non-operative treatment, but where there is any doubt, we believe that it is safer to open the abdomen and take a look, for the odds are surely against the patient when fecal contamination of the peritoneum from the rectum occurs, or there is an open wound of the bladder into the peritoneum as well, if we sit back and do nothing but watch and wait. It is not always easy to estimate the depth of penetration in these cases. The distance of the fall before striking the vulnerating agent and the weight of the patient may afford some information, but the statement of a bystander who pulled it out is seldom reliable. The best evidence of deep penetration, if it be present, as it was in the two cases about to be described, is the ability to feel the end of the pitchfork handle, or whatever it is, through the anterior abdominal wall. In such cases we believe the indication for operation to be clear and undisputible, and as early as possible after the receipt of the injury.

I shall now describe as briefly as possible two illustrative cases with bladder involvement. Only the second is one of my own, the complete history of the first having come into my hands recently through the kindness of my friend Dr. W. E. Morse, of Rapid City, South Dakota, who handled it himself throughout.

Case 1.—Impalement of the rectum by pitchfork handle, with penetration of the anterior wall of the rectum, extraperitoneal injury of the bladder and massive retrocystic hematoma formation. Laparotomy, drainage and recovery (Dr. W. E. Morse's case).

C. W—, Bonita Spring, South Dakota, male, aged twenty-two, while hauling hay, on July 16, 1930, threw a pitchfork to the ground from the hayrack and immediately jumped from the load of hay, landing on the pitchfork handle, the fork having stuck in the ground. The handle of the fork entered and penetrated the rectum for a distance of about 14 inches. The end of the handle could be felt a short distance above the pubes.

Examination showed the head, neck and chest free from evidence of disease or injury. The abdomen was acutely tender over the lower half, on both sides, with well defined rigidity of both recti. Rectal examination showed contusions in the anal area; the proctoscope revealed a perforation of the anterior wall.

Laparotomy under gas-ether anesthesia was performed within a few hours after the accident. It was found that the pitchfork handle had not penetrated into the peritoneal cavity but had stripped the peritoneum from the bladder to the anterior abdominal wall, with the formation of a huge hematoma in the traumatized area (Fig. 1).

The peritoneum was closed and the retrocystic traumatized area was drained by an extraperitoneal Penrose drain protruding anteriorly. A retention catheter of the mushroom type was left in the bladder and the patient returned to bed in good condition. Two days after the operation the patient was having a discharge of fecal material and gas through the retention catheter and a large amount of liquid which appeared to be urine was coming through the rectum. Eleven days after the operation, the intervening period having been quite uneventful, the temperature was normal, the patient feeling very well, there was less air coming through the bladder, less pain on urination and less fluid coming through the rectum. On the twentieth postoperative day the patient was sitting up and feeling very well; on the following day he was discharged from the hospital under observation, the rectal examination at that time showing that the channel of communication between the bladder and rectum was narrowed down to the size of a small lead pencil. Four days later he had to be readmitted on account of weakness, abdominal discomfort and pain in the rectum, due to fecal impaction in the rectum, relieved by enemies. Dr. Morse's records do not show the date of the final observation, but whenever it was the fistula had healed completely and the patient remained well.

Case 2.—Impalement of the rectum by pitchfork handle, with penetration of the rectum anteriorly, through-and-through penetration of the bladder into the peritoneal cavity and beginning peritonitis. Laparotomy, suture of the bladder, peritoneal drainage and tube drainage of the recto-vesical injury, recovery. (Author's case.)

R. P.——, Elkton, South Dakota, male, aged sixteen, was admitted on the morning of August 27, 1922, giving the following history: about 5:45 on the previous evening the patient jumped down from a wagon and struck a hay fork stuck in the ground, receiving the impact on his perineum. The fork handle entered the rectum and the end could be felt in front, just behind the anterior abdominal wall, a little below the umbilicus. Patient's father pulled out the fork handle. The immediate disability was slight; a physician who was called ordered hot applications and especially advised against any operation. During the night the father became alarmed by the boy's restlessness and complaint of increased pain, took him to a doctor in another town. This doctor catheterized the patient, obtaining only a small amount of fluid, although there had been no micturition since the accident, and also ordered him given an enema, which was found to contain some blood. This doctor realized the possibility of serious injury and brought the patient a distance of some sixty miles to me, early in the morning following the afternoon of the accident. I noted that the patient's facial expression appeared drawn and anxious, the pulse rapid and of none too good quality, the abdomen rigid throughout without localization and the lower abdomen tender to pressure. Rectal examination showed a longi-

tudinal tear 1 inch long in the anterior wall, through which urine dribbled. Diagnosis: pitchfork handle injury of bladder through the rectum with possible intestinal injury; acute diffuse peritonitis.

Operation was begun exactly fifteen hours after the time the injury was received. Under ether the abdomen was opened through a right paramedian incision below the umbilicus. On opening the peritoneum a large amount of turbid fluid escaped and several coils of injected small intestine flaked with fibrin appeared. A transverse opening in the upper anterior wall of the bladder, in the median line, about 1 inch long, was soon found and repaired with two layers of catgut, the first of which included only the fibrous and muscular coats, the second closing and inverting the peritoneal coat (Fig. 2). A rapid exploration of the pelvis failed to disclose any intraperitoneal injury of the large or small intestines except a superficial abrasion of the small intestine at one point. A large black rubber fenestrated drainage tube was placed in the lower angle of the abdominal incision extending down into the pelvis. The rest of the abdomen was closed and the patient placed in the lithotomy position. The wound in the perineum was closed with a couple of interrupted sutures and a fairly large black rubber drainage tube placed in the wound in the rectum which was found to lead directly into the bladder and anchored externally. He recovered nicely and was discharged on the eighteenth postoperative day.

Conclusions

No one surgeon sees enough of these cases to be able to build up a series on which to form any conclusions. Most surgeons who report cases have seen only the one; so far, in a fairly extensive search of the literature I have found none who has reported more. Many surgeons of wide experience have seen none. Under these circumstances it is difficult to formulate a plan of action based on statistical study, applicable to the management of these cases. Van Hook and Tillmans, in their papers, estimate the mortality rate, by and large, at about 30 per cent. However, in Van Hook's collection of fifty-eight cases, the thirty in which penetration of the peritoneal cavity did not occur, all recovered, with or without abdominal exploration, while 71.4 of those in which such penetration did occur died. Many of these latter were cases of delayed operation or no operation, and so the figures are elusive in their significance.

I believe that the safest rule to follow is that postulated by Van Hook and other writers, that "operative measures suitable to the nature of the case should be undertaken with as much promptitude after these accidents as in cases of abdominal gunshot injury."

Discussion

Dr. Walter A. Fansler (by invitation): I very much appreciate the privilege of discussing the papers of Drs. Cottam and McGandy. I had the opportunity of examining the patient of Dr. McGandy, and consider the result quite remarkable. He complained of a little difficulty in controlling a liquid stool or his bladder if over-distended, but I felt that even this was quite largely a mental hazard. I have seen two other cases of this type which might be briefly mentioned. In the first instance the patient, a male, was backing down a ladder on the side of a railroad car. He dropped from the last rung and his anal region struck the end of a crowbar which was sticking upright in the ground. The crowbar entered the rectum through the anal canal doing but slight injury to the anal canal. The rectum was pierced through the anterior wall at a point just above the prostate, the abdominal cavity being entered just posterior to the bladder. The abdomen was opened the following day by Dr. B. J. Branton of Willmar, who removed some pieces of overalls, and other extraneous matter. The rectum was repaired, and abdominal drains inserted. The patient left the hospital in two months with all wounds healed. I saw him sixteen months later. His complaint was a feeling of being unable to control his bowel. This, however, was a sensation, not a fact. He also stated that he had noted a little blood four days previously, and that he had pain during the act of defecation. A radiograph taken six weeks previously following a barium enema, was said to have shown some adhesions posterior to the rectum, but no interference with bowel function. The barium enema was retained without difficulty. Examination revealed that the anal canal could be dilated easily and painlessly to the diameter of one inch. The tone and contractible power of the sphincter was good. One and one-half inches from the anus on the midline of the anterior rectal wall, was a scar which extended upward and slightly to the left for 1.5 inches. It was well healed and not tender, and I felt the result was excellent. I saw the patient again six months later. At this time he complained of pain in the pelvis, particularly at night after a day of bending and stooping. He stated that the left lower portion of the abdomen swelled and that the scar of his abdominal incision was tender and painful. His appetite was poor and he had gas in his intestines. The findings upon examination were unchanged, and I could not but feel that the chief cause of symptoms was the threatened loss of compensation. I felt that operative procedure would be of no benefit and advised against it. However, his abdomen was explored at a later date by a local surgeon with the report of some adhesions about the signoid. My last report was that no benefit had been derived from the operation and my personal feeling was that no improvement would occur until the matter of compensation was settled.

The second patient was that of a young boy, sixteen years old, who was playing football on a vacant lot, from which the weeds had been cut, leaving some rather tall stumps. In the play he was pushed backward, sat on a weed-stump, which entered the rectum through the anal canal. The rectum was pierced on the anterior wall just above the prostate. I saw him in the General Hospital, sixty hours after injury. Rectal examination revealed the injury, but he had only a slight temperature and leukocytoses. He had slight distention and tenderness over the lowermost part of the abdomen. There was no abdominal rigidity, and we felt that, since sixty hours had elapsed with no graver symptoms than those present, we were justified in waiting further. In this case we were justified, as the boy's symptoms rapidly subsided and he was discharged from the hospital within a few days.

As has been pointed out, the occurrence of impalement or other similar rectal injuries, are so infrequent and the nature of the injuries so variable, that no predetermined or routine treatment has been determined. There are, however, certain facts which are of value when we are confronted with a patient suffering from this type of injury.

First it should be remembered that an elongated object entering the rectum will usually strike the anterior wall of the rectum, rather than the posterior wall which hugs the hollow of the sacrum. If the object be sharp, it will likely perforate at the first point of contact. If perforation does not occur here then it will almost surely take place near the site of the rectosigmoid juncture. At this point there is a distinct narrowing of the bowel, and just above there is a definite angulation. This angle is in some cases so acute that even

with the greatest care a proctoscope cannot be advanced around it. Therefore this is a common site of perforation. In a few instances this narrowing and angulation does not occur, and the rectum and colon form a straight tube entering the abdominal cavity. This is undoubtedly the case in those rare instances where the end of the object causing impalement can be felt high in the abdominal cavity, and yet bowel perforation has not occurred. It is, I think, of some practical value to remember that in almost all cases of impalement the site of perforation will be not more than 6 inches from the anus and likely, less. The injury therefore should be easily visualized by the use of an anoscope or a short proctoscope. If no perforation can be found in this area the chances are that one does not exist.

In attempting to make a diagnosis the giving of enemas or the inflation of the bowel with air during proctoscopic examination should be avoided as foreign material may be forced into the peritoneal cavity. The walls of the rectum should be cleansed where necessary with moist gauze or applicators, and proctoscopic examination made without inflation.

An x-ray examination is a valuable adjunct in many of these cases for it may reveal the presence of gas in the peritoneal cavity, especially in those cases where some time has elapsed since the injury. It may also reveal the presence of foreign material.

Doctor Cottam commented upon the frequent lack of hemorrhage in these cases. This is because the majority of perforations occur on the anterior walls of the rectum in the relatively avascular area above the prostate. The blood supply of this portion of the rectum is derived almost entirely from the superior hemorrhoidal artery. This artery bifurcates upon the posterior aspect of the rectum, only its terminal branches extending anteriorly. He has also emphasized the unreliability of the statements of persons who witness the accident and the early lack of shock and other evidence of severe injury in these cases, even where perforation of the abdominal cavity has occurred.

To recapitulate all of the points brought out in these papers and their discussion, the following salient points may be kept in mind:

1. In the majority of cases the site of bowel perforation will be found on the anterior wall of the rectum, and seldom more than six inches cephalad to the anal orifice. It can therefore be easily visualized with a short anoscope or proctoscope, and if no perforation can be found in this area the chances are that one does not exist. If such an opening is found, careful probing is justifiable.

2. X-ray examination may reveal the presence of gas or foreign material in the abdominal cavity.

3. Enemas and inflation of the bowel with air are unnecessary and dangerous in cases of perforation. Proctoscopic examinations can be done without inflation and the walls of the bowel can be cleansed with moist gauze or applicators.

4. Statements of witnesses of the accident must be accepted with caution.

5. Hemorrhage, shock, severe pain, or other evidence of severe injury are frequently lacking immediately following the injury, even though perforation of the abdominal cavity has occurred. This must be kept in mind lest the surgeon be tempted to follow the policy of watchful waiting rather than making a thorough investigation.

6. Immediate exploratory laparotomy should be done in all doubtful cases. To wait for active signs of perforation is to court disaster. The exploration of a normal abdomen is not serious, but it is serious to allow a perforated bowel to go without early attention.

Dr. C. D. Creevy: I have never seen an impalement of the rectum in which the bladder was injured. I should like to congratulate both Dr. Cottam and Dr. McGandy on the excellent results they have had in what must have been rather difficult situations.

My experience at the University Hospital includes one instance of impalement of the rectum with a pitchfork handle which entered neither the peritoneal cavity nor the bladder. The patient made an uneventful recovery without any operative therapy. I have seen one case of puncture of the sigmoid by a proctoscope which was repaired surgically within a few minutes of the accident but which caused death, indicating the virulence of the organisms that sometimes are present in the rectum. The rest of my experience has concerned lesions of a different type involving the rectum and bladder or urethra; included are a recto-urethral fistula which had followed a hemorrhoidectomy some thirteen years before. The communication was between the bulbous urethra and the anterior rectal wall just above the anal sphincter, so that the patient was able to void urine in a good stream through the anus, the urethra being shut off by a stricture just below it. The urine was clear. When the patient understood the nature of the operations that would be required he decided to continue his urination in the manner to which he had been accustomed for thirteen years. I still think this was a wise decision.

The second was a recto-urethral fistula following perineal prostatectomy done, of course, elsewhere, and which had already been repaired by Dr. Peyton, who did preliminary colostomy and cystostomy, followed by an operation similar to that which Dr. McGandy did in his patient.

The third was a case of a congenital communication between an imperforate anus and a prostatic urethra which was repaired by Dr. Wangensteen.

The only fistulous communication between the urinary tract and the bowel which I have seen and treated personally was one which followed a series of operations for intestinal obstruction, also done elsewhere, beginning with an appendectomy, followed by drainage, followed by intestinal obstruction, followed by an operation for the relief of adhesions which, in turn, three or four days after the operation, was followed by the passage of feces and gas through the urethra. The condition had been present for about six months following the last operation when the patient was admitted to the University Hospital and the diagnosis, of course, was perfectly obvious from the symptoms. I was anxious to secure some films which could be made into a lantern slide for demonstration purposes and undertook to demonstrate the fistula by means of the x-ray. Barium given by mouth and by rectum failed to enter any fistulous communication. A cystogram was made and failed to show any communication between bladder and bowel. An opening could be seen high up on the posterior wall of the bladder with a cystoscope quite readily but nothing could be passed through it. When the abdomen was explored it was found that there was a perforation in the terminal ileum which communicated with the posterior wall of the bladder and which was very readily taken down and repaired, after which there was an uneventful recovery.

Dr. T. H. Sweetser: I wish to mention the case of a young man whom I saw at the General Hospital in 1933, in order especially to call attention to the possible value of intravenous pyelography and cystography in cases of the type under discussion this evening. This man, during a game of horseshoes, sat between turns on a tin can placed upside down on one of the iron stakes used in the game. The bottom of the tin can bulged farther each time he sat on it, and finally gave way and the stake entered the rectum. He developed abdominal pain in both lower quadrants, especially on the left; there was no nausea or vomiting and no external bleeding. He was given a hypodermic injection and sent to the hospital, where, on examination, only a

tenderness and spasticity of the lower abdomen were found.

Exploratory laparotomy disclosed an intact peritoneum but marked edema of the tissues in the region of the rectum; no mention was made of the bladder. Four days later I was asked to see him because the urine at the time of admittance had showed blood, and later blood and pus cells. I suggested intravenous urography; I haven't heard that mentioned in the discussion thus far. There was noted thereby a mild bilateral hydronephrosis and hydro-ureter, and, more important in this case, a lack of concentration of the dye in the bladder, due apparently to leakage of urine into the surrounding tissues or into the rectum. Cystoscopy showed a wound in the base of the bladder and bits of clothing in the bladder cavity. The bladder was opened suprapubically, clothing, urine and feces removed, and the wound in the bladder base closed with a mattress suture of forty-day chromic catgut, avoiding the mucosa of bladder and rectum and pushing the knot down behind the bladder. A Freyer tube was placed for drainage. The urine, clear at first, showed some fecal contamination temporarily after three days, but cleared soon. The operative wound healed well and he voided easily and went home in excellent condition thirty-one days after his accident and twenty-six days after the cystotomy.

In this discussion, I wish mainly to call your attention to the safety and possible diagnostic value of intravenous urography in such cases.

Dr. H. W. Christianson (by invitation): I saw a case where a pitchfork tine had perforated through the rectum into the bladder. An indwelling catheter was placed in the bladder and a small drain was placed in the wound located in the rectal wall. This drain was removed in a few days and nothing further was done. The patient made a complete recovery.

One important fact might be brought out regarding the packing of these wounds. Drains or gauze packing should not be left in longer than is absolute necessary as they may produce a permanent sinus or fixed scar. This rule applies to any fistulous tract.

Accidents involving impalement of the rectum are very serious and it is, therefore, important to find out at once if the wounds are extra-peritoneal or intra-peritoneal.

Dr. Willard White: I would like to mention briefly a boy I saw at the General Hospital about 1925, as I remember. He had been playing ball and broke the bat. He put the blunt end of the bat on the ground and had a piece of board that he put across the upper or sharp end, and sat on this. Something happened so that he lost his balance, the board tipped up and the sharp end of the broken bat went into his rectum, penetrated the anterior wall of the rectum, through the posterior wall of the bladder and out through the fundus. I happened to be at the hospital on another emergency and I saw the boy about two hours after the accident, at which time there was very definite rigidity in the lower abdomen. We were satisfied that he had peritoneal irritation. We opened his abdomen and found urine and fecal material in the abdominal cavity and these perforations I mentioned.

These perforations, the two in the bladder and one in the rectum, were sutured. One point I would like to make now which I think you all know but may fail to remember and which is a very valuable thing in connection with extensive soiling such as you get in this type of thing. Pour in a great deal of normal salt solution and suck it out with the suction apparatus because it has been demonstrated with experimental animals that pathogenic organisms can be placed in the abdominal cavities of dogs and if the abdominal cavity is washed out thoroughly immediately and closed without drainage, about 80 per cent of these dogs will survive, whereas if they do the same thing except that they do not wash out the peritoneal cavities practically all of the dogs will die. It is a very good idea to irrigate the abdominal cavity and then use the suction apparatus.

An indwelling catheter was left in this boy and he got a bilateral epididymitis. There was some infection in the abdominal wound. However, he recovered. I followed him for a number of years. Since that time he has married and has at least two children. That was of interest to me because I wondered whether or not his bilateral epididymitis was going to sterilize him.

Dr. H. F. Bayard (by invitation): All of the cases reported here this evening have resulted in a favorable outcome, in spite of the fact that, as Dr. McGandy cites, the mortality rate reaches a level of something like 30 per cent. Two of the three cases within my experience have resulted fatally.

The first of these was a man who slipped off a runway while watching concrete being poured on a construction job. He impaled himself on one of the corrugated reinforcing rods protruding up above the concrete; this rod was somewhat over an inch in diameter. The injury was a complete denudation of the perianal skin, perforation of the lateral wall of the rectum as well as perforation of two loops of ileum. Peculiarly enough, this man made a recovery.

Another case, seen in consultation, resulted in a fatality. This case, as are many of the rectal traumatic lesions, was due to perforation of the lateral wall of the rectum by the handle of a pitchfork, the end of the perforation tract being at the base of the mesentery in one of the lower loops of bowel. A large postrectal abscess developed and was drained but an adynamic ileus and peritonitis developed and the boy died, as I recall the case, about one week after exploration of his abdomen.

These are usually very serious injuries and we should not be misled into thinking that the injury carries a low mortality rate.

The meeting adjourned.

Harvey Nelson, M.D., *Secretary.*

The Prevention of Paralysis in Poliomyelitis

The seasonable outbreaks of infantile paralysis are not far distant. Last week a statement in the correspondence column of The Journal emphasized the necessity for complete rest for patients in the early stages of this disease. Complete rest is so important that it is usually far better to leave the child in bed at home when the disease is first suspected than to move the patient any appreciable distance to a hospital. When these patients are disturbed or moved as little as possible a majority in whom the disease has not progressed beyond the early stages escape paralysis entirely. Should the patient have paralysis, especially of the extremities, the affected part should be immobilized properly at the earliest moment. Early rest of a weakened muscle under these circumstances will help prevent permanent crippling. Infantile paralysis can be suspected when there is fever, headache, irritability, possibly vomiting, perhaps a tremor in the hands, and especially a tender rigid spine, which makes it impossible for the child to touch his chin to his knee. When such manifestations are present, the spinal fluid may be examined to confirm the diagnosis. Thus far there is no specific effective remedy in the acute stages of infantile paralysis nor any generally accepted preventive.—(Jour. A.M.A., May 14, 1938.)

MEDICAL BROADCAST

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 9:45 o'clock every Saturday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

June 4—Chronic Illness.
June 11—Burns.
June 18—Arthritis.
June 25—Orthodontia.

HENNEPIN COUNTY MEDICAL SOCIETY

Dr. J. S. Reynolds was elected president at the annual meeting of the Hennepin County Medical Society, held May 2, 1938. Other officers elected were: Dr. W. E. Patterson, first vice president; Dr. F. J. Pratt, second vice president; Dr. L. M. Daniel, secretary-treasurer, and Dr. T. A. Peppard, librarian.

Dr. F. A. Willius, of Rochester, addressed the members on "A Less Common Manifestation of Rheumatic Heart Disease."

NORTHERN MINNESOTA MEDICAL ASSOCIATION

Announcement has been made by the program committee that the fall meeting of the Northern Minnesota Medical Association will be held at Crookston, Minnesota, on Monday and Tuesday, August 29 and 30. Further announcement as to the program will follow in a subsequent issue.

REDWOOD-BROWN COUNTY

The Redwood-Brown County Medical Society held its annual meeting at the Turner Hall in New Ulm on Wednesday, May 4. The meeting was preceded by a banquet with the Ladies Auxiliary, following which Dr. J. G. Love and Dr. Bayard Horton of the Mayo Clinic gave talks respectively on "Diagnosis and Treatment of Head Injuries," and "Histamine Treatment of Migraine Headaches."

Election of officers resulted as follows: President, Dr. Walter G. Nuessle, Springfield; vice president, Dr. Howard Vogel, New Ulm; secretary-treasurer, Carl J. Fritsche, New Ulm; censor for three years, Dr. Francis C. Gibbons, Comfrey; delegate to 1939 convention, Dr. Cornelius A. Saffert, New Ulm; alternate, Dr. Kenneth L. Olson, Gibbon.

The Medical Economics or "Contact Committee" was unanimously re-elected: Dr. Albert Fritsche, New Ulm, Chairman; Dr. T. F. Hammermeister, New Ulm; Dr. O. J. Seifert, New Ulm; Dr. E. J. Wohlrabe, Springfield; Dr. A. P. Goblirsch, Sleepy Eye.

SOUTHWESTERN MINNESOTA SOCIETY

A highly successful interprofessional dinner meeting was sponsored by the Southwestern Minnesota Medical Society on April 28 at the Hotel Thompson in Worthington.

Eighty-five men, representing dentists, lawyers, physicians and others, were present.

District Judge Charles A. Flinn introduced the first speaker, who was Mr. James H. Hall, president of the Minnesota State Bar Association. Dr. L. M. Cruttenden of Saint Paul, secretary of the Minnesota State Dental Association, followed him. Dr. Cruttenden was introduced by Dr. C. L. Perrizo, also a dentist, of Jasper. Dr. Cruttenden reviewed the history of dentistry since the establishment, one hundred years ago, of the first dental college.

Dr. B. J. Branton of Willmar, councilor of the third district, represented the physicians on the program. Dr. C. L. Sherman of Luverne, president of the Southwestern Society and of the Southwestern Sanatorium Board and member of the State Board of Medical Examiners, introduced Dr. Branton. Dr. Branton's theme was application of the Golden Rule in the relations between physicians and all of their professional associates.

WRIGHT COUNTY MEDICAL SOCIETY

The Wright County Medical Society met at Delano on Wednesday, April 20, twenty-two doctors being present. Dr. H. M. N. Wynne and Dr. R. I. Rizer of Minneapolis spoke on "Endocrines."

The home economics class of the high school served a four course dinner for the doctors and their wives at 6:30. During the afternoon the ladies were entertained by Mrs. A. E. Phillips and Mrs. Theodore Greenfield, at Mrs. Phillips' home.

POLIOMYELITIS WITH SPECIAL REFERENCE TO THE DRINKER RESPIRATOR THERAPY*

ALBERT V. STOESSER, M.D., and WALLACE S. SAKO, M.D.

Minneapolis, Minnesota

EACH year, more and more information concerning acute anterior poliomyelitis is placed on record. Some reports deal with the etiology of the disease, others with the diagnosis and many suggest new forms of therapy.

In the last six months of the year 1937, a fairly large number of cases of poliomyelitis were admitted to the University and Minneapolis General Hospitals. These patients were closely followed and interesting observations were made. The majority of the patients were admitted during the months of August and September. Three-fourths of these were between the ages of one and fourteen and the lowest mortality was found in the years from five to nine. There was an equal distribution as to sex. The size of the family did not seem to influence the incidence of the disease. There were no cases of second attacks.

In this series, the average maximum temperature was 103.9 F. and the white blood cell count averaged 8,900. The leukocyte count showed no definite relation to the temperature, indicating the blood response and presumably the antibody response to be slow or absent. The majority of the spinal fluid cell counts were between 50 and 100. The cell count generally fell gradually from the level found at the onset of the disease until the period just preceding the most extensive paralysis. At this time it rose again, falling slowly thereafter. The polymorphonuclear cells in the spinal fluid slowly decreased as the disease progressed and the mononuclears correspondingly gradually rose until about the fourteenth day, when they were practically one hundred per cent. The course of the disease could not be predicted by the temperature, the white blood cell count or the spinal fluid findings.

The distribution of the paralysis was of interest. There were fourteen cases with paralysis of the muscles of the trunk and abdomen. This was a higher number than was expected. Most outstanding, however, was the incidence of cases having respiratory difficulty. Minnesota has experienced during the past ten years three periods during which there have been an unusual number of cases of poliomyelitis. Each time there has been a corresponding increase in the number of patients admitted to the hospitals. Among the hospital cases the incidence of patients with difficulty in breathing has increased until during the latter half of the past year it reached a rather alarming figure. Seventy-nine cases of poliomyelitis were admitted to the University and Minneapolis General Hospitals from July 1, 1937, to December 31, 1937, and of this number twenty-nine patients had some respiratory distress. Tables I and II summarize these observations.

Thunberg, in 1926, first used the barospirometer for artificial respiration. The patient was entirely enclosed in an air-tight cylinder. Drinker, Shaw and McKhann[4,5] reported, in 1929, a modification of the barospirometer so that the patient's head could be outside the air-tight cylinder. Since then the Drinker respirator has been widely used for the treatment of respiratory failure in poliomyelitis. In Minnesota, however, where respirators are scarce, physicians must

know the indications for this form of therapy especially in view of the fact that the recent small epidemics of poliomyelitis have been accompanied by a high incidence of cases with respiratory embarrassment. Some patients respond very well to the Drinker respirator; others do not respond and are even made worse. Physicians tend to place all their cases with respiratory difficulty into the machine. The authors feel that this is a poor procedure and offer, therefore, in this brief communication, the newer knowledge of the Drinker respirator therapy.

The most important problem is the careful selection of the patients for treatment. The following classification has been found to be of great assistance.

Spinal Cases

Spinal cases in which there is a direct paralysis of the muscles of respiration innervated by the nerves from the dorsal and cervical spinal cord. The intercostal muscles, the diaphragm, or both, are involved. Paralysis of the intercostal muscles is determined by watching the expansion of the chest during inspiration. The magnitude of expansion is more readily estimated by pressing firmly on the upper abdomen, thus diminishing the excursion of the diaphragm. Paralysis of the diaphragm is determined by observing the movement of the abdominal wall during inspiration. If there is no abdominal movement, or if the abdomen is drawn inward during inspiration, it indicates weakness or paralysis of the diaphragm.

The individual with spinal respiratory paralysis usually advances to the stage where he lies in bed motionless, the eyes having a fearful stare. The face is dusky and the lips are cyanotic. The alæ nasi dilate with every inspiration and the accessory muscles of respiration, especially the sternocleidomastoid, are visible with every inspiration. The chest and the abdomen become practically vibrationless. The patient cannot sleep, but when he is placed in the Drinker respirator the response is usually dramatic. The cyanosis disappears and the face assumes its natural color. The facial expression is that of satisfaction. After the patient's breathing and the respirator become synchronous, the individual falls into a deep sleep which may last many hours.

The early respirators had three speeds: 15, 30 and 45 per minute. Later models had two speeds: 15 and 30 per minute. The latest type is so constructed that all degrees of speed can be obtained and the machine can be tilted as desired. Eight of our patients with respiratory difficulty were of the spinal type and all were placed in the Drinker machine. None of these died in the respirator although one died after removal from the machine, of peritonitis which followed a recto-vaginal fistula. The initial rate of 30 per minute was used in the majority of our cases, and then the rate was adjusted to correspond as nearly as possible to the normal respiratory rate of the patient—faster in children and slower in adults. Children were started at about 10 cm. of negative water pressure, which was gradually increased with age to 15 cm. or 20 cm. for adults. In each case the machine was operated at the lowest negative water pressure at which the patient had complete relief of symptoms.

The patients placed in the respirator remained in it undisturbed except for rotation from side to side several times daily. The efficiency of the respiratory muscles was observed when the machine was opened to give nursing care. If

improvement began, the respirator was opened for longer intervals and then, following the suggestions of Emil Smith,[12] the patients were asked to cough. If they could, they were removed from the machine and watched carefully for cyanosis. However, when the patients were able to breathe without effort but could not cough, they were kept a part of each day in the machine until such time as they were able to cough.

There was some mechanical difficulty in giving adequate nursing care to the patients in the respirator. The disadvantages of the machine were as follows:

1. The temperature was difficult to regulate.
2. The frequent incontinence of urine and sometimes of feces increased the tendency to skin irritation.
3. The rubber collar was uncomfortable and irritated the neck.
4. Early orthopedic treatment could not be carried out as desired.

Bulbar Cases

Bulbar cases in which there is involvement of the nuclei of the cranial nerves with apparent injury of the respiratory center. The damage to the bulbar nerves supplying the muscles of the pharnyx and the larynx is often ushered in by a nasal quality of the voice, by choking attack or by regurgitation of fluids through the nose. Various grades of aphonia and impaired ability to cough or swallow are present. Advanced cases may be heard breathing with an ominous gurgling in the throat. Attempting to swallow causes a choking attack. Secretions around the glottis which seem to prevent deep inspirations, cause the breathing to simulate paralysis of the respiratory muscles. Deep inspirations tend to aspirate fluid into the larynx and are frequently interrupted by a forced expiration. However, extreme irregularity of breathing, both as to depth and rhythm, is an indication of damage to the respiratory center.

Nine of our patients had pharyngeal paralysis with some interference in proper breathing. None was treated with the Drinker respirator and all recovered. Two patients also had facial paralysis, and this cleared up satisfactorily. There were, however, six bulbar cases with definite respiratory difficulty. Two patients were placed in the Drinker respirator but they did poorly and expired in a short time. It was apparent that the machine caused aspiration of material from the throat and at the same time overcame the reflex choking and coughing by which this material could be ejected. The next case, therefore, did not receive the respirator therapy, the following measures being substituted:

1. The foot of the patient's bed was elevated to facilitate drainage of secretions away from the larynx and into the posterior pharynx, where they were removed by suction.
2. Postural drainage was used during the choking spells when the condition of the patient permitted.
3. Nothing was given by mouth and vomiting was almost eliminated. Plenty of parenteral fluid was administered and large whole blood transfusions were also given.

In spite of these procedures, the patient rapidly became worse. Choking attacks occurred with temporary severe anoxemia resulting in deep cyanosis. Aspiration of mucus and vomitus into the bronchial tree took place, producing evidence of bronchial obstruction leading to a complete cessation of breathing at times. Excessive fatigue due to the continual interference with inspiration by the unswallowed material in the pharynx or the actual inspiration of this material was the cause of death. However, the three remaining patients did not have such an extensive involvement of the bulbar nerves as was present in the previous case. All were treated without the Drinker respirator by the method outlined above. At first, it was difficult to refuse the use of the respirator to these cases, but as they progressed favorably the thought of using the machine vanished.

Bulbo-spinal Cases

Bulbo-spinal cases have, as the term indicates, both spinal and bulbar involvement. This is manifested by paralysis of intercostal muscles, the diaphragm, or both, and some paralysis of the pharynx. If the paralysis of the pharynx is unilateral, as indicated by difficulty in swallowing, the respirator may be effective. If the paralysis of the pharynx is bilateral, as indicated by a total inability to swallow, the machine is ineffective. This was easily demonstrated by the fact that five of our six bulbo-spinal patients were placed in the Drinker respirator, and none survived. They all had a bilateral paralysis of

the pharynx. The one patient who did not receive the Drinker respirator therapy was not very ill. He was frightened by the machine and fought it. There was only a partial involvement of the muscles of respiration and a unilateral pharyngeal paralysis. This patient recovered.

The pathological lung changes in patients who have expired in the respirator have always been of great interest to those taking care of poliomyelitis patients. The following changes are commonly reported in the literature:[9] (1) rupture of the alveoli due to emphysema; (2) pneumothorax; (3) pulmonary atelectasis; (4) pulmonary congestion; (5) pneumonia.

Most of these conditions can be eliminated in the spinal respiratory cases if the machine is used properly and the patients are systematically turned and carefully nursed. However, those with the more severe bulbar involvement die and at necropsy reveal changes such as were found in our group, namely: pulmonary edema, bloody fluid in the pleural cavities, subpleural petechial hemorrhages, and hemorrhagic bronchopneumonia.

The experience gained from our small series of cases has confirmed the observations of other writers who state that those unfamiliar with respiratory failure in poliomyelitis are apt to overestimate the value of the respirator in this disease because they fail to differentiate the types of respiratory failure. The spinal respiratory case has a very good chance of being saved by the machine. On the other hand, in the bulbar type with glosso-pharyngeal and vagus involvement the respirator often offers little help. Tables III and IV emphasize still more the importance of the foregoing statements.

TABLE IV. SUMMARY OF TREATMENT OF POLIOMYELITIS CASES WITH RESPIRATORY DIFFICULTY

University and Minneapolis General Hospitals, July 1, 1937–Dec. 31, 1937

Type of Case	Treatment	Total Cases	Recovered	Died
Spinal respiratory with paralysis of intercostal muscles and diaphragm	A	8	8	0
	B	0	0	0
Bulbar with pharyngeal and/or laryngeal paralysis	A	2	0	2
	B	13	12	1
Bulbo-spinal with paralysis of respiratory muscles and pharyngeal paralysis	A	5	0	5
	B	1	1	0

A—Cases treated with the Drinker respirator.
B—Cases in which the Drinker respirator was not used at any time.

Summary and Conclusions

Recent small epidemics of acute anterior poliomyelitis in Minnesota appear to reveal an increasing incidence of cases with respiratory difficulty. The respirator devised by Drinker and McKhann has been found to be of great help to the patients with difficult breathing. However, all patients are not benefited to the same extent.

Proper selection of the patients is essential. This is especially important in epidemic periods when the number of Drinker respirators available is less than the demand. Our experience with a small number of cases has shown the respirator to be of unquestionable value in the treatment of those patients with high spinal involvement. The machine gives them the rest so essential for recovery.

The Drinker respirator is of little or no value in the care of patients whose respiratory difficulty is bulbar in origin. The machine may overpower the choking and cough reflexes and in some cases even cause forcible aspiration through the larynx of secretions from the throat.

The bulbo-spinal cases may respond to the Drinker respirator provided the pharyngeal paralysis is unilateral. If the paralysis is bilateral and the patient cannot swallow, the machine is ineffective.

SYPHILIS IN THE TRANSIENT*

PAUL A. O'LEARY, M.D.

Rochester, Minnesota

DURING the past few months you have noticed in the press or have heard over the radio considerable discussion about syphilis and gonorrhea. A campaign has been launched for the dissemination of knowledge in regard to syphilis, similar to the educational program regarding tuberculosis which has been actively carried on for many years. There are many reasons why the time seems appropriate for the carrying out of such a program, and I shall discuss this shortly. It is worthy of comment, however, that in the years gone by the editors of newspapers believed that their readers were not ready for such a campaign and that they could not use the words "syphilis" and "gonorrhea" in the public press. This attitude has gradually changed, and newspapers and magazines now contain information in regard to the venereal diseases. Surgeon General Parran of the United States Public Health Service precipitated the idea of such a campaign and has enthusiastically established it as a nation-wide enterprise. That the people of this country are in the mood to receive information about venereal diseases is evidenced by the fact that the momentum of the campaign has carried it from the hands of the Surgeon General to become a problem managed by the individual states.

There are numerous reasons why syphilis should be discussed in public rather than behind closed doors, as has been the case heretofore. We now have data based on extensive research which permits us to say without reservation that early

*From the Department of Dermatology and Syphilology, The Mayo Clinic, Rochester, Minnesota. Read at the Midwest Conference on Transiency and Settlement Laws, Saint Paul, Minnesota, March, 1937.

syphilis is definitely curable. I should like to emphasize the fact that cure applies to early syphilis. When we speak of late syphilis, that is, when the disease has passed the early stage, we are compelled to speak of an arrest of the disease rather than cure. By "arrest" we mean checking the progress of the disease in the heart or other internal organs. We know, now, that we can cure 85 per cent of the patients who come to us with a fresh infection and follow out the course of treatment which is recommended. It is by proper treatment of early syphilis that the late complications of the disease can be avoided.

Another reason why we are ready for a program of publicity is the success of such undertakings in Europe. The campaign in Denmark has been highly successful. There were less than 200 new cases of syphilis last year in Denmark, and I believe that in about thirty of these cases the patients were sailors who apparently had acquired the disease in some foreign country. In England, likewise, the campaign has been effective and has materially reduced the number of new cases of syphilis in that country. This decrease in the number of new infections is due not only to the fact that the treatments are furnished free but rather to the more important stipulation that the patient *must* remain under treatment until released by his physician.

A significant point for consideration is that in most cases of syphilis and gonorrhea the disease is acquired between the ages of seventeen and thirty-two years. Youths at this age are not impressed with the seriousness of the disease and, in most instances, are unable financially to arrange for proper treatment; this fact is, no doubt, a not infrequent cause of transiency. These boys are afraid of transmitting the disease to some of the relatives and because of their embarrassment and shame start out "on the road," spreading the disease as they go. Not only is it necessary that treatment be made available to these patients, but it must be made compulsory so that they will be forced to remain under treatment until they are no longer infectious, or able to transmit the disease.

Syphilis is infectious only during the early phase of the disease and is seldom infectious after the fourth year of its existence, regardless of whether the patient has received treatment or not. In other words, if an individual has had syphilis for more than five years and has been treated, there is practically no danger of his spreading the disease. In a man who has acquired syphilis and has had some treatment and has married five years after he acquired the disease, the likelihood is that his wife will not be infected and accordingly his children will not have the disease. However, if he marries within the first five years after he acquired the disease, the chances are that he will infect his wife, who in turn will infect the children, since the disease is transmitted to the children by the mother. This limitation of the infectiousness of the disease makes it an ideal disease for a public health program. We can absolutely eliminate the problem of infectiousness in cases of early syphilis by the adequate treatment of the patient. Treatment for two weeks will so heal the acute lesions that the infected individuals cannot spread the disease even though they will not be cured during this short time. We cannot do this with tuberculosis or other diseases of an infectious nature. Syphilis, therefore, lends itself to a universal health program because it is an ideal disease for the application of successful public health measures.

When I was first asked to discuss my impressions of the medical needs of transients, I was rather chagrined because I had had no contacts with transients. I did, however, have access to some reports on the incidence of venereal diseases among transients. It is unfortunate that no definite or concrete program was established in regard to venereal diseases early in the plans for the care of transients. The statistics which I was able to gather were from scattered sources and their interpretation was influenced by the enthusiasm of the medical officers who happened to be in control of the various areas. The United States Public Health Service at their Venereal Disease Clinic at Little Rock, Arkansas, took care of 1,125 patients with syphilis in 1934. Eight hundred forty-nine of these were on relief and 276 were self-supporting. Of these patients, 65 per cent were between the ages of sixteen and thirty years; 24 per cent had acute syphilis, 63 per cent had latent syphilis, and 13 per cent had late syphilis. The 63 per cent who had latent or dormant syphilis may or may not have been in need of treatment. They were not, however, in an infectious state and hence were not a menace to the community. They may have been in need of care and perhaps room and board, but

they were not of particular danger to anyone. Thirteen per cent had late syphilis, that is, syphilis of the heart or liver or nervous system. These patients were in need of treatment, perhaps in need of hospital care, to keep them from becoming state or county charges.

I have emphasized this particular group of figures because they represent incidence of damage from syphilis as it affects the populace as a whole. We know that less than a third of patients who have syphilis are going to have serious trouble from the disease, while two-thirds of those infected will have little if any trouble from the infection.

In Baltimore, there were 55,000 transients, of whom slightly less than 10 per cent had syphilis. Among the colored males, however, the incidence of syphilis was 23 per cent.

The Emergency Relief Bureau of New York City examined 40,000 men, of whom 3,100, or 8 per cent, had syphilis.

The report from Minnesota was obtained from two sources: Camp Independence and the Medical Health Center in Minneapolis. Camp Independence, during the three years of its existence, reported to the State Board of Health, 1,023 patients who had venereal diseases—702 had syphilis and 321 had gonorrhea. Of the 702 syphilitics, 176 had acute syphilis and hence were in danger of transmitting the disease. I have not been able to obtain statistics on the incidence of gonorrhea that are worthy of discussion. At the Minneapolis center, a group of 2,783 men received special examinations for evidence of syphilis. Of this number, 308 had syphilis and 107 had a history of syphilis; in other words, 11 per cent had syphilis. The reports on gonorrhea revealed fifty cases of acute gonorrhea and 700 men who gave a history of having had gonorrhea in the years gone by. The incidence of syphilis among colored men was 35 per cent.

Thus far I have been endeavoring to establish the fact that syphilis among transients is not a new problem. Syphilis among transients has always been a problem to those of us who have been interested in the disease. We will be able to do more, however, with more money available. I say this, having in mind the greatest appreciation for what has been done by the medical profession and charitable groups who for many years have given of their time, effort, and even material things for these patients, all of which has been contributed without thought or hope of compensation.

From these reports we find that the incidence of syphilis among transients is only slightly higher than is the estimated incidence among the populace as a whole. The United States Public Health Service estimated that 10 per cent of adults in this country have syphilis. The reports indicate that in the transient groups in the large cities, in the South, and in the Northwest, the incidence of syphilis varies from 10 to 21 per cent among the white population and up to 37 per cent among Negroes. The incidence of gonorrhea could not be estimated.

Under the provisions of the Social Security Act, the United States Public Health Service has available money which may be used for a venereal disease campaign. The law specifies that this money be allotted to the various states according to population, special health problems, and financial needs, at the request of the state health officials supported by the governing state authorities. The tentative plan of the campaign against venereal disease, as outlined by Surgeon General Parran, has as its general theme the elimination of syphilis and gonorrhea by making proper treatment available to all who need it. Some of the features of this campaign are worthy of emphasis.

For example, we have no accurate statistics as to the incidence of syphilis, so one of the first features of the program will be to require that all patients who have syphilitic disease be reported to the state boards of health. The reporting of these patients is a requisite in many states at the present time. A second feature is that treatment for syphilis is to be available, free of charge, to anyone who seeks it. In some states the Health Department will furnish to physicians the necessary remedies, such as salvarsan, bismuth, and mercury, on request. The number of venereal disease clinics is sufficient to give adequate care to patients in the majority of the urban centers, but in the rural districts such provisions are lacking and it will be necessary to create some method whereby the patients in these communities will be treated and the doctor who cares for them will be paid for his efforts. A fourth important point in the venereal disease campaign will be the organization of a group of field workers by the state health departments. It will be the duty of these workers to trace all

contacts, to arrange for the care of pregnant women who have syphilis and for the care of children who have congenital syphilis, and to locate and return for treatment patients who have had acute syphilis but who have discontinued treatment. When a diagnosis of gonorrhea or syphilis is made by a physician and treatment instituted, his problem does not end there but must include an effort to examine the individuals exposed to this patient. The success of this campaign will, in a great measure, depend not only on the efficiency of this "contact corps" but also on the creation of laws that will require these patients to remain under treatment until they are no longer a menace to their neighbors.

A fifth important item is provision of hospital beds for these patients. Patients who have acute syphilis should be isolated until they have been rendered noninfectious. The patient who has syphilis of the heart or liver, or late syphilis of the nervous system, may also be in need of a hospital bed, and just as much so as any other patient in the hospital.

I wish to emphasize also the effort to standardize the state laboratories where the diagnostic tests for venereal diseases are carried out. This is a technical detail which is already being worked out.

Finally, we must disseminate by the press, in pamphlet and in magazine, and by radio, knowledge regarding these diseases. A program for the postgraduate training of physicians in this field, under the combined direction of the state medical society, the public health service, and the American Medical Association, is also essential to the success of this plan.

What, then, are the medical needs of the transient who has a venereal disease? May I call attention again to the fact that venereal disease among transients is not a new problem to those of us who have been concerned with venereal diseases for these many years. True, we may have a different name for these patients, but the problem is no more acute. The evidence clearly indicates that the incidence of venereal disease among the unemployed is lower than it is among a low wage earning group. In the State of Minnesota, the patient who has venereal disease and is in need of treatment has not been neglected if he has sought aid. True, if neglect was evident, it occurred particularly in the rural areas, or if it occurred in the cities it resulted from the refusal of the patient to continue the treatment recommended by the clinics. I do not believe that anyone in the State of Minnesota who was in need of treatment for syphilis and applied for it was ever refused such treatment. In other words, I am endeavoring to establish the fact that there is no need for undue excitement or extreme measures to combat a problem that has been with us for a long time and that has in this state been rather well taken care of by the medical profession and the health department, in accordance with the funds granted them and abetted by the generosity of those who have given of their time and efforts gratuitously. The granting of additional funds to the State Health Department, which has been in direct contact with the problem, and has handled it very satisfactorily for the last twenty years, will permit of the early and rapid establishment of additional personnel trained in the epidemiology and the treatment of these venereal diseases.

I have made mention of the fact that this is not a problem involving only the transient; it involves indirectly or otherwise the entire populace of this commonwealth. The evidence indicates that the incidence of venereal diseases among transients in the Northwest is lower than it is in the South, due no doubt to the fact that venereal diseases are more common among the colored race. It is shown from the statistics gathered in this state that about 10 per cent of the transients will have syphilis, and that of this number a third will be in need of active treatment and two-thirds will have the disease in mild form. This last group is not infectious and consequently not a menace to the community. Treatment is given in the early cases with the idea of cure and of preventing the patient from spreading the disease. In the late cases it is given for the purpose of arresting the disease, extending life expectancy, and maintaining the individual's capacity as a wage earner. I have been informed that there will be some 6,000 or 7,000 unemployed men in this state during the coming summer months, of whom approximately 700 will have syphilis. Of this number approximately 250 will be in dire need of treatment. If this treatment is to be effective and if the patient is to derive benefit of a worth-while nature, regulations must be enacted to compel him to remain under treatment until dismissed or at least released as noninfectious. The experience of the

United States Public Health Service has shown that patients who have early syphilis have continued treatment on an average of six weeks, whereas cure in early syphilis is not possible before six months of continuous treatment, as an absolute minimum, has been given. The entire campaign will fail if measures are not at hand to compel these patients to remain under treatment until they are cured. The transient who has venereal disease must be cared for either in a transient camp or in an institution already provided with equipment and personnel for the care of these diseases, or by the local physicians. The granting of additional funds to these already established agencies will readily provide for care of the transient in the urban areas. The occasional case encountered in the rural communities can best be treated by the local health officer or physicians.

The medical profession of this state has, through a duly appointed committee,* agreed to encourage and work wholeheartedly in the campaign against venereal diseases. The Minnesota State Board of Health has played an active part in combating the disease by the treatment of these patients. With additional financial help they could reëstablish and maintain treatment facilities adequate not only for the transient but for the people of the state who need such medical care. In closing, may I emphasize that the transient who has a venereal disease is, after all, as he has been for many years, the problem of the health department. He is merely one part of the entire venereal disease problem in the state, which, if it is to be cared for efficiently, should be handled by a unit of the health department which is organized, experienced, and ready to cope with the entire problem in this commonwealth.

CHORIONEPITHELIOMA WITH REPORT OF A CASE*

Survey of Incidence in Saint Paul Hospitals

CHARLES W. FROATS, M.D., F.A.C.S.

Saint Paul, Minnesota

CHORIONEPITHELIOMA is a rare malignant tumor arising from the chorionic epithelium of the fetal villi following hydatidiform mole, abortion, and term pregnancy. The tumor may develop before the products of gestation have been expelled and has been described as occurring in the tube and ovary. Sänger, in 1889, first recognized the disease and applied the term "deciduoma malignum." Marchand, in 1895, correctly identified the tumor cells as derivatives of both layers of the chorionic epithelium and his views gradually became accepted. In 1898, he proposed the name chorionepithelioma.

Individual reports differ as to the incidence of chorionepithelioma. In a period of eighteen months, seven cases were found in 2,700 autopsies in Vienna. According to Curtis,[3] Symmers at Bellevue found none in 12,000 autopsies. Curtis,[4] in a coördinated clinical experience with Watkins covering sixteen years, found none, although constantly on the lookout. As noted by Gough,[8] Kimbrough (1934) observed two in 8,375 confinements; Winter (1934), three in 8,000 confinements; St. Sommer (1934), one in ten years among 18,000 confinements; and Joravieff (1933), one in 26,000 confinements. Sherman[17] (1935) in a thirty-four year study of hydatidiform mole at the New York Lying-in Hospital found one in 182,119 obstetrical and 14,280 gynecological patients. Schumann[16] (1937), in an analysis of its frequency in Philadelphia over a five-year period covering 207,707 pregnancies, found fifteen, or one in 13,850 pregnancies. Cosgrove[2] (1938) reported three developing in 20,450 confinements at the Margaret Hague Maternity Hospital.

The true etiology of this disease is unknown. In all but rare exceptions pregnancy has preceded the growth. Teacher[18] reported a series in which the age incidence ran from seventeen to fifty-five years, averaging thirty-three. The majority occur in multipara. It is a disease of the child-bearing years and of fertile women, with

*Presented at the annual meeting of the Minnesota Society of Obstetrics and Gynecology, Saint Paul, Minnesota, April 23, 1938.

the incidence paralleling the degree of fertility. In Teacher's[18] monograph he found 8 per cent with the first pregnancy, 15 per cent with the second, and 28 per cent with the second and the third. Lynch and Maxwell[11] report the statistics of Briquel as 21 per cent occurring in the second pregnancy, 20 per cent with the third, and 47 per cent with the fourth or more.

Antedating so many chorionepitheliomas, hydatidiform mole has been considered as a predisposing condition. From Polloson and Violet's series of 455 cases, as reported by Curtis,[3] 45 per cent were found occurring after hydatidiform mole; 30 per cent after abortion; 21 per cent after labor at term; and 2.5 per cent followed ectopic gestation. In a series of 500 cases of hydatidiform mole, Findley[7] stated 31.4 per cent were followed by chorionepithelioma. Bell[1] gives the statistics of Sunde as 44 per cent occurring after hydatidiform mole; 30 per cent after abortions; and 22 per cent after labor at term. In 1922, Novak[14] estimated one per cent of moles became malignant and Teacher[18] believes five per cent too high. Polak[15] (1931), in discussing a paper on choriomas by Schmitz, stated that in ten years he had seen forty or fifty cases of moles and none became malignant and in the same interval ten chorionepitheliomas were not preceded by moles. In Schumann's[16] report, eight of the fifteen chorionepitheliomas were preceded by moles, while in Cosgrove's[2] analysis all three cases developed after molar pregnancies. With the incidence of malignancy following mole as 5 per cent or more, this in itself must be considered a grave condition.

The location of the tumor is most commonly in the area of the placental site. Grossly it invades the uterus as a soft, vascular mass, usually differentiated from the mucosal layer. It may be located on the endometrium, in the myometrium, or may grow through the wall and protrude into the peritoneal cavity or broad ligaments. The tumor, microscopically, is composed of masses of syncytium and nests of Langhans cells independent of villi with penetration into the wall of the uterus. There is invasion of blood vessels, mitosis of Langhans cells, very little stroma and intravillus vessels or lacking entirely. Hemorrhage and necrosis is common. The two types of cells vary in proportion in different tumors. Attempts have been made to classify these tumors. Mathieu and Palmer[12] and Gough[8] prefer Ewing's classification into: chorioadenoma, choriocarcinoma and syncytial endometritis. It is considered one of the most malignant and destructive neoplasms known. The reported mortality rate varies from 10 to 60 and 70 per cent. Findley[7] states there is a higher recovery rate from chorionepithelioma following mole than from that following abortions and full term pregnancies.

The period of latency varies from a coexistent appearance with the pregnancy to months and years. Usually it follows in weeks or months but may occur any time thereafter during the life of the patient. Metastases occur by way of the blood stream. Lesions in the lungs and vaginal walls are usually the first to appear.

Lutein cysts of the ovaries are regularly observed as in hydatidiform mole. They are usually bilateral and vary from small multiple cystomata to large tumors. These are probably due to excessive hormonal influence with stimulation of follicle growth and luteinization. Several investigators have shown that they are the result of excessive pituitary stimulation.

The usual clinical symptom is persistent bleeding following abortion, molar pregnancy or full-term pregnancy. The greatest difficulties are encountered in early abortions, where the bleeding may be thought to be due to placental remnants, and after labor wherein the physiologic bleeding may obscure the development of the growth.

The clinical value of the Aschheim-Zondek (1928) reaction for the study of normal and abnormal pregnancies has been well demonstrated. This biological test for anterior pituitary-like hormone is now an established aid in the diagnosis of chorionepithelioma. A number of authorities have shown that in hydatidiform mole and chorionepithelioma the amount of gonadotropic substance is much greater than that excreted during normal pregnancy. Due to the abnormal activity of the chorionic elements in these conditions the hormone secretion is increased to such an extent that even high dilutions result in positive reactions. On the basis of a quantitative reaction both the Aschheim-Zondek test or the Friedman modification may be used as a diagnostic aid. Ehrhardt[6] obtained a positive reaction in a case with 1/520 c.c. of urine and in another with 1/260 c.c. Levanthal and Saphir[10] reported 330,000 mouse units per liter of urine

in an early case and Kurzrok[9] observed a reaction as high as one million mouse units.

As recorded by Mazer and Edeiken,[13] in 1929 Fels and Roessler made several observations, namely: that with hydatidiform mole and chorionepithelioma much higher quantities of prolan are secreted than in normal pregnancy; the quantitative estimation of the hormone is an accurate guide in differentiating both of these conditions from uterine bleeding in the course of pregnancy due to other causes; presence of increased hormone for longer than two weeks after normal pregnancy or more than eight weeks after a mole pregnancy is pathognomonic of chorionepithelioma; continued presence of the hormone after the complete removal of the growth is indicative of metastasis.

Only living chorionic tissue causes positive reaction and the reaction becomes positive before clinical diagnosis of metastasis can be made. Mathieu and Palmer[12] diagnosed two early cases with the history of a mole and the persistence of anterior pituitary-like hormone in the urine. If a positive reaction should recur after having been reported negative following the expulsion of a mole, care should be exercised in differentiating between a new pregnancy and chorionepithelioma. With the advance of pregnancy, prolan concentration increases and twin pregnancies show a higher titer than single. Herein the quantitative biologic test lends a most definite aid, but should not be the determining factor to the exclusion of the history and clinical findings.

In the opinion of a number of investigators the biological test is more dependable than the findings from examination of uterine scrapings. Histological diagnosis from curettings is not always easy and may be inconclusive or even misleading. To establish the diagnosis by this method the operator must obtain a portion of the growth invading the wall of the uterus. Mistaken diagnoses have resulted in delay of proper treatment or the unnecessary removal of pelvic organs. Curettage is unreliable in that the growth may be located away from the uterine cavity in the myometrium. Levanthal and Saphir[10] (1934) and Cosgrove[2] (1938) each reported a case in which curettage would have been of no value. Moreover curettage carries the danger of perforation, infection, and possible dissemination.

Two reports have been made on a negative Aschheim-Zondek in the presence of chorionepithelioma: one by Fahlbusch in 1930, related by Mathieu and Palmer,[12] and another in 1937 by Schumann.[16] Schumann[16] believes radical operation is indicated whenever persistent fetal elements are found, especially if bleeding occurs, in spite of negative Aschheim-Zondek reaction.

The degree of malignancy cannot be predicted, and the prognosis depends on early recognition. The hope of curing any malignant disease depends on recognition in its early stage of proliferation. It is therefore advisable to have repeated Aschheim-Zondek or Friedman tests made in all women who continue to bleed after the expulsion of a mole, or in those with abnormal bleeding of an undetermined cause following pregnancy. Titus[19] suggests performing the test every two weeks until negative, and thereafter every four weeks for six months. Mathieu and Palmer[12] recommend monthly tests for one year.

Upon the diagnosis of this disease the early removal of all tissue containing malignant elements would be the ideal treatment. The clinician is then confronted with the question as to which type of operation offers the best hope of cure. The usual procedure has been to perform an abdominal panhysterectomy with removal of both tubes and ovaries. The abdominal operation permits better exposure and there is less trauma to the tissues. Lynch and Maxwell[11] advised the most extensive removal that the individual case will stand. Mathieu and Palmer[12] believe that in chorionepithelioma diagnosed early and the growth confined to the uterus it is unnecessary to remove the ovaries if they appear normal. They report an early case with only supravaginal hysterectomy and no recurrence after two years. Gough[8] maintains the lutein cysts are due to the disease and of no causative significance, and that the removal or conservation of the ovaries is optimal. He recommends the removal of the cervix. Total hysterectomy was the method of choice in Cosgrove's[2] three cases and no recurrences had appeared after 26, 23 and 11 months.

Few reports have been made of treatment by irradiation, its use having been limited chiefly to inoperable cases and metastatic growths. Davis[5] (1936) reports its successful use following supravaginal hysterectomy in a case complicating a placenta previa. In his opinion operable cases should be preceded or followed by thorough radiation. Titus[19] recommends preliminary radia-

tion with radium, followed by hysterectomy and a subsequent course of deep x-ray therapy. Irradiation should be effective as the growth is of fetal origin and such tumors are particularly susceptible to this kind of therapy.

The records of six representative hospitals in the city of Saint Paul were reviewed to determine the local incidence of chorionepithelioma.

Hospital A, 1928 to 1937 inclusive, reported 430 abortions, 6,310 confinements, one mole—no chorionepithelioma.

Hospital B, 1927 to 1937 inclusive, reported 589 abortions, 4,941 confinements, one mole—no chorionepithelioma.

Hospital C, 1928 to 1937 inclusive, reported 270 abortions, 2,995 confinements, one mole—no chorionepithelioma.

Hospital D, 1932 to April, 1938, inclusive, reported 1,279 abortions, 8,150 confinements, seven moles—no chorionepithelioma.

Hospital E, 1932 to April, 1938, inclusive, reported 365 abortions, 3,705 confinements, three moles—no chorionepithelioma.

Hospital F, December, 1920, to April 7, 1938, inclusive, reported 330 abortions, 7,282 confinements, four moles—no chorionepithelioma.

In a total of 3,263 abortions, 33,383 confinements and 17 moles (36,646 pregnancies in all), there was no record of a chorionepithelioma.

It should be stated that one of the hospitals reported one mole and four chorionepitheliomas. However, upon investigating two of these charts and the pathological reports, they were omitted as entirely inconclusive. Of the remaining two, prepared sections of the surgical specimens were submitted to Dr. E. T. Bell for examination. Dr. Bell reported no chorionepithelioma present.

Report of Case

The following constitutes the report of a chorionepithelioma of the uterus antedated by the expulsion of an hydatidiform mole.

Mrs. J. S., thirty-four years of age, married at twenty-two, had five children living and well. There was a history of a spontaneous miscarriage at four or five months in March, 1934, unattended by a physician. Menses were regular until mid-summer, the last menstrual date not being definitely known. She first consulted her physician August 16, 1934, complaining of a tired, worn-out feeling and nervousness. His examination showed her weight to be 142 pounds, blood pressure 128/75, and hemoglobin 70 per cent. She was again seen August 30, 1934, and under medication her hemoglobin had risen to 80 per cent and she felt some better. On September 24 she reported again with the complaint of slight uterine bleeding, but no associated cramps. Examination revealed a uterus about two and a half months pregnant. The patient was put to bed for one month, including one week of hospitalization. The bleeding recurred upon being upon her feet. On November 7 abortion was induced by the bougie method after consultation with another physician. The induction was successful and a mass the size of a fist was expelled, described as meaty in appearance. The specimen was examined by Dr. E. T. Bell and reported as hydatidiform mole. Moderate bleeding continued for three weeks and several particles of tissue were passed. On November 30, 1934, the physician performed a dilatation and curettement with the removal of particles of vesicular tissue. This tissue was not examined. December 19, 1934, the uterus was of normal size and no bleeding had occurred. January 2, 1935, the patient reported to her physician that bleeding had recurred that day.

The patient was first seen by me in consultation January 4, 1935, with the complaint of uterine bleeding of two days' duration, and slight lower abdominal cramps. The amount was described as slightly in excess of the usual menstrual flow. There had been no evidence of bleeding for thirty-three days following the dilatation and curettement.

The family history was essentially negative.

Examination showed a well developed woman of 138 pounds weight, temperature 97.2, pulse 80, blood pressure 118/72, chest and abdomen normal. Pelvic examination: vulva, urethra, and glands negative; perineum somewhat relaxed; vaginal walls normal in appearance; old healed lacerations of cervix with chronic cervicitis present; fundus retrodisplaced, uniform in outline with the suggestion of being slightly enlarged; nothing palpable in either adnexal region. Laboratory findings: urine normal; hemoglobin 75 per cent; red blood count 4,000,000; white blood count 10,500.

Bearing in mind the history of the mole, it was, nevertheless, assumed that this was her first menstrual period following the dilatation and curettage, and retrodisplacement and slight subinvolution of the uterus was determined. It was suggested to the patient's physician that hormone tests for the presence of persistent hydatid reaction be made and that she be observed for the possible development of malignancy. On January 26, 1935, a Friedman test was positive. This was an undiluted specimen. The physician reported that she was continuing to have a slight bloody discharge off and on. February 27, 1935, a Friedman test was again positive. Through a misunderstanding the request to the laboratory for dilution of the urine was omitted. Her physician reported that irregular bleeding continued and the uterus was enlarged.

The patient was again seen by me March 12, 1935. Bloody vaginal discharge had continued at intervals. General examination was much the same as on previous visit. Her weight remained the same and the temperature was normal. Pelvic examination: inspection of vulva and vaginal walls showed no implants; thin bloody discharge from cervix; uterus definitely enlarged to the size of a 3 to 3½ months pregnancy, quite uniform in outline and slightly tender; adnexæ

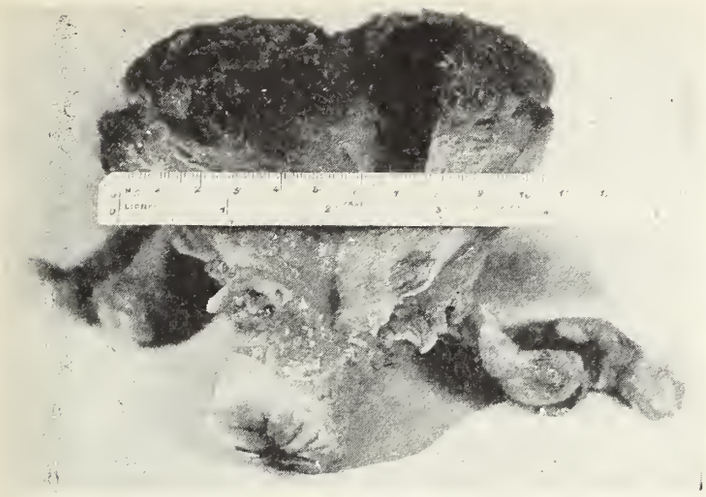

Figure 1. Photograph of gross specimen showing the entire uterus and its appendages with the anterior surface incised to expose the tumor in the fundus.

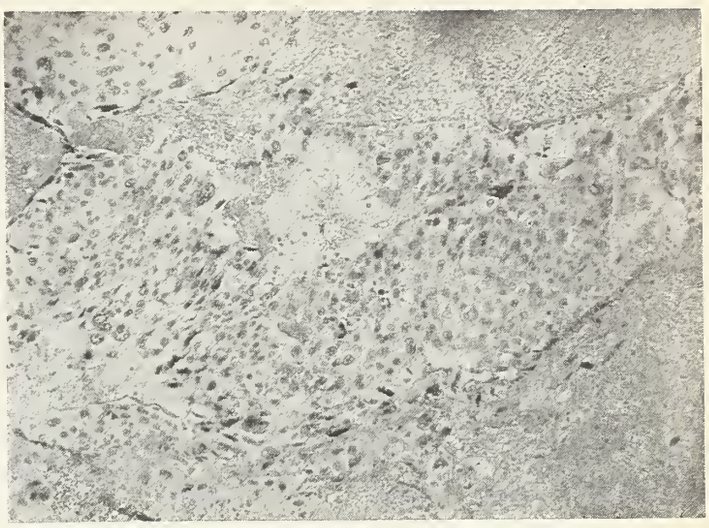

Fig. 2. Photomicrograph showing masses of chorionic epithelium in the uterine muscle independent of villi. The tumor cells are largely the Langhans type, but there are a few syncytial cells at the periphery of the section.

not palpable. Laboratory findings: hemoglobin 72; red blood count, 3,870,000; white blood count, 11,200; differential—lymphocytes, 33, large mononuclear 1, neutrophiles 65, eosinophils 1 per cent. Sedimentation rate moderately rapid, Wassermann negative, blood grouping 11. X-ray of chest negative for metastases. A clinical diagnosis of chorionepithelioma was made and operation advised.

On March 15, under spinal anesthesia, the abdomen was opened. The uterus was enlarged to the size of a three and one-half months' pregnancy. The growth, confined to the fundus and slightly nodular on the serous surface, presented a striking multicolored appearance. The ovaries were only slightly enlarged and cystic. A panhysterectomy was carried out, with the removel of both tubes and ovaries.

The uterus and its appendages weighed 320 grams. The inside diameters of the tumor measured roughly 5 by 7 cm. The pathologic report made by Dr. E. T. Bell of Minneapolis was chorionepithelioma of the uterus; numerous follicular and luteal cysts of the ovaries.

The patient made a good recovery and was discharged from the hospital March 29, 1935, on her fourteenth postoperative day. Deep x-ray therapy consisted of a total of 143 per cent skin erythema dose to the pelvis in ten treatments over a period of eighteen days, through four portals.

No immediate biological tests were made on this patient following surgery and radiation. The follow-up of this patient has been restricted to personal communications. The first one of these was received in July, 1936, in which the patient stated she had gained 17 pounds in weight, and, except for being a little nervous, felt well and worked hard every day. Recent communications in the last few weeks from both the patient and her physician were to the effect that she remains in good health and there is no evidence of recurrence. I believe that she may be considered cured.

Subsequently, on May 12, 1938, a Friedman test was negative.

Summary

1. The subject of chorionepithelioma has been reviewed.

2. The incidence of chorionepithelioma among 36,646 pregnancies and abortions in six Saint Paul hospitals has been given, substantiating the reported rarity of the condition.

3. A case report has been presented.

SPINA BIFIDA CYSTICA OF THE PELVIS: DIAGNOSIS AND SURGICAL TREATMENT*

ALFRED W. ADSON, M.D.

Rochester, Minnesota

A PATIENT who recently came to The Mayo Clinic because of spina bifida cystica of the pelvis presented an unusual problem for diagnosis because of the location and rarity of the lesion and also because a new operative procedure was required. This experience I believe justifies a report of the findings and the surgical technic employed. Since there still remains some confusion about the types of operations to employ for spina bifida, and some uncertainty about the proper time to operate, I shall review our experiences in the general discussion of the subject.

Spina bifida is one of the common deformities of the newborn; it occurs once in 1,000 to 2,000 births. There are two varieties. One is known as spina bifida cystica and the other as spina bifida occulta. The spina bifida cystica has three subdivisions. The first is simple meningocele, which represents a herniation of the meninges through a defect in the spinal canal. The cystic wall is composed of arachnoid and dura, which are covered with thinned fascia and skin. The meningocele contains no nerve elements. The second variety is known as myelomeningocele. This is similar to a meningocele except that nerve roots enter the wall of the cystic mass. The third variety is known as a syringomyelocele. It resembles the first variety in that it is composed of a sac but differs from the first and second varieties in that it contains a dilated portion of the conus medullaris, and nerve fibers end blindly in the wall of the sac. The first variety is rarely associated with any form of paralysis; the second variety is associated with a varying degree of sensory or motor disturbance; the third variety usually is associated with very marked paralysis. At this point, I should like to emphasize that a plastic repair on the cystic mass rarely improves the paralysis. Therefore, the parents of the patient should be informed of this fact before operation is performed.

An associated hydrocephalus of the communicative type may accompany any one of the three varieties. However, it is most frequently associated with the third variety. If the two coexist, each requires separate surgical consideration. It has been observed that a repair of a large cystic spina bifida in cases in which there is no obvious evidence of hydrocephalus may result in a hydrocephalus as the spina bifida has served as a reservoir during the early weeks of life. Spina bifida may occur in any portion of the spinal canal. It occurs more frequently in the lumbosacral region than in other parts of the spinal column. However, it does occur in the craniocervical and in the cervical region, but it is rarely seen in the upper thoracic region. The spinal defect may include from one to ten vertebræ.

Spina bifida occulta is characterized roentgenographically by a bifid spinal column and by the appearance of a small dimple covered by a tuft of hair. It rarely produces clinical symptoms in early life, but the progressive myelodysplasia may cause symptoms later in life. This manifests itself by increasing sensory and motor disturbances and impairment of the rectal and vesical sphincters.

Analogous to the developmental defects of the spinal cord observed in the later stages of spina bifida occulta is a condition that is known as myelodysplasia, except that it occurs without a demonstrable bony defect.

Etiology

One of the oldest theories, strongly championed by Morgagni in 1779, rejected by most writers since von Recklinghausen's[12] comprehensive dissertation on spina bifida, in 1886, and recently rediscovered and espoused by numerous writers, is the theory of hydromyelia. According to this theory the choroid plexus, activated perhaps by a hormone, secretes such a large quantity of spinal fluid that it either prevents union of the medullary folds or ruptures them after union has taken place. Interference with the absorption of spinal fluid is advanced as the alternative mechanism. The rapid accumulation of fluid then is given as the primary cause; the resulting cyst is

*From the Section on Neurologic Surgery, The Mayo Clinic, Rochester, Minnesota. Thesis presented before the Minnesota Academy of Medicine, April 13, 1938.

interposed as a bulging mass between the lateral mesodermal structures, preventing the approximation and fusion of the lips of the medullary groove. One of the main supports of this theory lies in the fact that spina bifida is often associated with hydrocephalus, which is rapidly made worse or, if not already present, may rapidly be produced by operative closure of the spinal defect. The assumption of an excessive amount of spinal fluid obviously depends on the further assumption that the choroid plexus is secreting fluid at this early embryonic period. This hypothesis seems inadequate when the whole problem is considered; one of its most serious objections is the fact that the choroid plexus does not begin secreting fluid until about the tenth week, 2.4 mm. embryo (von Monakow),[9] whereas all writers agree that the spina bifidous deformity is produced no later than the third week. Further, the cases in which there is a failure of the entire neural canal to close certainly represent a more serious type of the same fundamental defect and must accordingly be explained on the same basis; it seems highly improbable that the amount of spinal fluid secreted is so immense that the entire canal, from its cephalic to its caudal ends, would be torn open or union prevented throughout by the flow of the choroidal secretion. Complete absence of the cord, or amyelia, which accompanies many of these severe types (Schmaus and Sacki)[13] must also be explained by a more comprehensive theory. Mention of micromyelia, diastomyelia, and diplomyelia, which occur with spina bifida and without it, would still further embarrass the theory. It is also irreconcilably at variance with the observation that the portion of the spinal cord involved lacks all evidence of pressure myelitis, with its disintegrating nervous tissue; on the contrary, it is seen to have remained at a standstill in its embryonic development, with embryonic nerve cells and embryonic blood vessels, as the area medullovasculosa (von Recklinghausen).[12] Associated defects, such as harelip, cleft palate, and club feet, are considered by recondite inference to be the results of pressure on the nerve centers. While it must be admitted that the added area of absorption supplied by the cyst often prevents the occurrence of hydrocephalus, it would seem more reasonable to suppose that the faulty absorption of spinal fluid may also be based on some developmental defect. An associated cardiovascular defect has been suggested as a possibility.

von Recklinghausen[12] believed that spina bifida is primarily due to a failure of the mesodermal envelope of bone and dura to approximate; he looked on the ectodermal dysontogenesis as secondary. The fact that a myelodysplasia of this type may occur without defects in the bone controverts this theory; it suggests that the defect may be primary in the medullary plate. The types of spina bifida cystica and spina bifida occulta not accompanied by defects in the nervous system argue for the reverse. The necessity for making one primary and the other secondary is not apparent. Whatever the exact mechanism may be, it does not complete our search for the more fundamental process in which we are primarily interested.

There is much evidence against assuming that the basis is germinal, or developmental, and such cause has been generally discarded. I do not believe that this is altogether justified. Thus, the presence of developmental defects in one case, in which the closely related defect of enuresis and sacral dimple were transmitted to six persons on the male side, through three generations, is clearly an instance of heredity. Two other cases, in which the same defect appeared in siblings, do not furnish conclusive evidence, since maternal environmental factors might have been just as potent and quite as likely as developmental factors. On the whole, the hereditary element hangs on a very tenuous thread; it must be assumed for occasional cases, but these are not numerous enough to argue for its acceptance as the sole cause.

Experimental Production of Spina Bifida and Other Anomalies

Recent work[17] among biologists cannot be disregarded as some writers are disregarding it simply because it has been carried out on lower forms of life. The experimental production of spina bifida by modification of the environmental medium has taught us a great deal. A brief review of this evidence is profitable. Probably the most striking demonstration of the importance of environment in the production of spina bifida was that produced by Hertwig,[5] in 1896, who subjected the axolotl, a salamander, to different concentrations of sodium chlorid solution. He found that a 0.5 per cent solution had no

effect, a 0.6 per cent solution produced monsters in 50 per cent, while 0.7 per cent solution resulted in development of spina bifidous monsters in every case. Stockard, using *Fundulus heteroclitus*, the common minnow, produced spina bifida by using magnesium chlorid. Cyclops could be produced in at least 50 per cent of cases, which was somewhat more frequent than spina bifida. It was also demonstrated that alcohol, ether, and the alkaloids could be used with similar results.

In order to demonstrate the applicability to man of these factors of monster production, Werber used substances produced in the human metabolism, namely butyric acid and acetone. He exposed *Fundulus heteroclitus* in the two, four, eight, and sixteen cell stages, to the action of 1-12/1-14 gm. molecular solution of butyric acid in sea water, from fifteen to twenty hours; he produced a great variety of monstrosities, the extreme defect being the development of only an eye or an ear, the rest of the embryo failing to appear. Higher percentages of acetone killed the embryos, while lower concentrations resulted in the development of monsters. Werber[15,16] concluded that faulty maternal metabolism might well be the underlying cause of dysontogenesis. Disastrous maternal effects of diabetic patients are well known. Keibel and Mall[6] found that the chorion of nearly all monsters had been the seat of inflammatory processes which in time might well have interfered with normal metabolism. The frequent association of hydramnios makes this all the more probable.

Chemical methods are not the only ones by which monsters have been produced artificially. One of the other simplest devices is a modification of gravitational forces on frogs' eggs. Simply turning upside down (Conklin)[4] frogs' eggs in the two-cell stage may cause the development of double-headed or double-bodied monsters. A redistribution, by centrifugalization, of the heavier elements of the eggs constitutes another method. In the ascidian (sea squirt) eggs, in which different kinds of protoplasm give rise to different organs and tissues, this rearrangement may result in marked dislocation of organs. That the problem is complex is shown by the fact that some varieties develop normally in spite of this artificial rearrangement (Morgan).[10]

Lewis[8] adopted the remarkably simple method of destroying different portions of the eggs of *Fundulus heteroclitus* by operation-needling, and so forth, and demonstrated that the organs predetermined in the portion of the egg destroyed did not develop. He could thus produce a developmental defect in any portion of the body he desired. Kellicott found that subjecting the eggs of *Fundulus heteroclitus* to a temperature of the average household refrigerator, for a few hours or days, sufficed to produce every variety of defect.

That physicochemical action may produce developmental mental defects was demonstrated by Bardeen,[3] who exposed both male and female frogs to the x-ray for one hour, prior to fertilization. He learned that exposure to the x-ray of the ovum or the sperm sufficed to influence the subsequent development of the eggs in such a manner that marked abnormalities, including spina bifida, resulted. Baldwin[2] produced spina bifida in frogs by exposing a given part of the egg to the action of the ultra-violet ray.

The mechanism by which various factors influence the developing organism is also disputed. I can only refer to these briefly. Mall assumed that nutritional factors *in utero* resulting from diseased fetal members underlie monster production. Werber postulated the theory of blastolysis, according to which a part or wedge of the germ substance is destroyed, resulting in anomalous fusion or dispersion of the part split off. Stockard[14] believes that he has proved, by the use of magnesium with its well-known anesthetic or inhibitory action, that an inhibitory action is responsible. Kellicott,[7] espousing the hypothesis of disorganization, believes that this must take place before differentiation by gastrolysis, through interference with the organization of the fertilized ovum. The discovery of the deleterious action of the x-ray and radium on the sperm, prior to fertilization, added another complication, since it proved that an abnormal character of the gametes may in some instances suffice to produce the defect.

von Recklinghausen's demonstration that the area medullovasculosa contains elements retaining early embryonic characteristics is of fundamental importance and prohibits the acceptance of the current theories, in the strictest sense, as an explanation of the large group of cases not dependent on hereditary factors; or is it possible that lack of abnormality of function and metabolism, secondary to the apparent isolation of

these elements, in the area medullovasculosa suffices to explain their embryonic appearance.

In view of the foregoing clinical observations and the facts adduced through experimental methods, it seems that spina bifida cannot be explained on the basis of any single factor, but by one or more of the following causes: abnormal character of the gametes or mechanical, chemical or physico-chemical factors influencing the embryonic rudiments, either before or after differentiation; the mechanistic action of accumulated cerebrospinal fluid could act only as a secondary cause. A conception as broad as this seems to destroy all semblance of a theory; indeed, any precise formulation of a theory which does not take all these factors into account would be dogmatic, premature, and untenable at the present stage of knowledge.[17]

Symptoms

The physical deformity of a spina bifida cystica is obvious. The cystic masses vary in size from those which are similar to an English walnut to those which are larger than a grapefruit. The roentgenogram reveals the extent of the bony malformation. The neurologic examination reveals findings according to location and extent of the involvement of the nerves or spinal cord. It does not disclose any change in the presence of a meningocele, it shows but few nerves missing when a myelomeningocele is present and gives evidence of marked anomalies of the nerves and spinal cord if a syringomyelocele is present. Hydrocephalus[11] frequently accompanies the third variety but rarely is associated with the other two, and never is associated with a spina bifida occulta.

Surgical Considerations

Oftentimes surgeons are called upon to repair spina bifida cystica as soon as it is observed after birth. Occasionally, this can be done with success, but, judging from our own experience, it is evident that operations on babies carry a much higher mortality than do operations that are performed at a later date, let us say, at a period from six to nine months following birth. There are other advantages in waiting. First, an apparent hydrocephalus may not be evident at the time of birth but will be evident in six to nine months following birth. Second, neurologic findings are often difficult to demonstrate in a small child. Therefore, by waiting for six to nine months it becomes much easier to demonstrate neurologic findings. A third reason for delaying the operation is that the parents can observe for themselves whether or not an accompanying hydrochephalus exists and whether or not any paralysis is caused by the anomalous condition. They should be thoroughly informed of these findings and should also be instructed concerning the results of the operation. They should be told frankly that the operation consists of a plastic closure and that the operation will not alter the hydrocephalus nor will it restore any function to the paralyzed extremity. It is well to go into detail concerning the object of the operation. The parents should be told what to expect in the way of results. The two first varieties, namely, meningocele and myelomeningocele, lend themselves to surgical treatment, but the syringomyelocele rarely presents a true indication for surgical treatment. Occasionally, one finds it advantageous to repair the cystic mass, but little is accomplished by attempting to free the conus medullaris from the scar tissue. Occasionally, one is able to free nerve filaments in order that they may fall back into the lumbosacral canal. When this is possible there may be some subsequent improvement in that particular nerve.

If an accompanying hydrocephalus exists, it is usually of the communicative type. Occasionally, repeated spinal punctures and limitation of the fluid intake may control the situation. If the child is a particularly healthy one, the surgeon may be justified in performing a Tracy-Putnam operation. This operation includes two separate openings of the lateral ventricles, through which the choroid plexus is coagulated for the specific purpose of decreasing the amount of cerebrospinal fluid secreted. Unfortunately, neither procedure guarantees that the hydrocephalus will be controlled. Since it is impossible to guarantee a control of the hydrocephalus, there is danger that the plastic repair may not hold and that leakage of cerebrospinal fluid may follow; when this does occur, there is always the danger that meningitis may develop.

If the obstetrician, as well as the parents, have been convinced that the plastic repair of the spina bifida cystica should be deferred until the child is six to nine months of age, they both ask two questions: (1) "How shall the spina bifida be cared for?" (2) "In the event that it leaks, how shall the leakage be controlled?" In our

experience we have observed that the spina bifida can be protected nicely by the application of a doughtnut-like ring that is made of cotton and held in place with roller bandage. The ring can be fastened to the back with adhesive plaster. It serves as a wall about the cystic mass and thus prevents undue pressure on the mass if the patient is lifted or allowed to roll on his back. With this protection, the child can be handled just as any other child is handled during the early months of life. Frequently, abrasions or ulcerations are present on the thinned-out skin in the dorsal portion of the sac. When these occur, the macerated area can be treated with sterile petrolatum, or preferably sterile borated petrolatum. The crusts can be removed from time to time with pledgets of cotton soaked in liquid petrolatum which has also been sterilized. After the abrasion has healed, the cystic tumor should be washed daily with soap and water, and powdered with any good antiseptic powder. If a rupture has taken place, so that the cerebrospinal fluid leaks from the cystic mass, we find that a similar treatment may be employed, except that the child should be kept more or less in the prone position on a pillow, with the head slightly lower than the cystic mass, which prevents any hydrodynamic pressure on the sac itself. Occasionally, one is justified in aspirating the sac; this is done by sterilizing the skin at the base of the sac and introducing a needle through normal skin, directing the needle superficially into the midportion of the sac. Following aspiration of the sac, it is well to apply gentle pressure with a binder over a sterile cotton dressing. The cotton dressing never should be applied directly on a macerated area. It is much wiser to cover the macerated area with a strip of vaseline gauze before applying sterile cotton dressings.

The reason for waiting from six to nine months is that it allows one to evaluate the situation, to determine the degree of paralysis, if any exists, and to determine whether or not there is a coexisting hydrocephalus. It also allows the child to develop so that additional feedings of gruel and semisolid food can be given. The reason for not waiting longer than nine months is that the operation, if it is to be performed, should be performed before the child attempts to stand, for at this time he is very likely to fall onto the sac and thus press it unduly.

In selecting an operation, one should choose an operation that will permit a thorough exploration of the contents of the spina bifida before a plastic closure is made. It is unwise to employ the older technic, which consists of freeing the sac along its base, tying and transfixing it without an observation from within, as it may include a knuckle of roots or cord when in reality they have not become a part of the sac. There is no need to worry about a recurrence of the spina bifida cystica if there is no hydrocephalus. We have learned that it is unnecessary to employ any sort of bone graft, since a good plastic closure suffices to protect the nerves or cord in the spinal canal. This argument is substantiated by the fact that one never sees a spina bifida cystica result following a laminectomy for fracture of the spine or for the removal of an intraspinal tumor.

Spina Bifida Occulta

The symptoms that result from the associated myelodysplasia make their appearance in early adult life. They are characterized by deformity of the feet, disturbance in the reflexes, the appearance of sensory changes and the loss of control of the bladder and rectum. The symptoms increase as the age of the patient increases. Exploratory operation has been performed in a number of these cases. Some investigators have reported lipomatous masses which they believe have been responsible for the symptoms. Others have found hypertrophy of the ligamentum flavum, but unfortunately the surgical results have been rather disappointing, since the degeneration takes place in the conus medullaris whenever the lesion involves the lumbar or sacral region. Spina bifida occulta is not confined to the lumbosacral region and fortunately may exist without producing clinical symptoms.

Surgical Technic.—The patient is anesthetized while on his side.[1] Ether, administered by the drop method, is the anesthetic most commonly used. After the patient has been anesthetized, he is placed on his abdomen over a pillow with the head lower than the spina bifida cystica, in order that the cerebrospinal fluid will not drain from the ventricles when the sac has been opened. The skin is thoroughly cleansed with green soap, washed with ether or alcohol, and a solution of merthiolate is applied as an antiseptic. Following adjustment of the sterile linen, the sac is opened longitudinally in order to permit an internal exploration of the sac. If no nerve ele-

ments are present, a circular incision is made in the meninges peripheral to the defect in the spinal column, in such a manner as to permit an apposition of the meningeal flaps over the defect. Occasionally, it is advisable to reflect a flap of lumbar fascia across and suture to the opposite side in order to reinforce the closure of the meninges. After removing the redundant tissue the wound is then closed. It is preferable to use number 0 chromic catgut for the subdermal sutures. The skin is closed with interrupted silk sutures and the wound is covered with collodion dressings. Collodion dressings have the advantage of protecting the wound from contaminations of urine and feces. In the event that nerve elements have been found to enter the walls of the sac, it may be necessary to resect these along with the redundant tissue, but whenever it is possible to free nerve filaments or a portion of the cord and permit it to fall into the spinal canal, this should always be done. The freeing of adhesions oftentimes does permit a number of nerve elements and occasionally the cord to seek their former position, but even though this has been accomplished, too much credit should not be given to the operative procedure in the hope that additional recovery will take place in the paralysis. I have seen improvement in sphincteric control.

In the event that paralysis does exist as a result of the anomalous condition of the nerve and spinal cord, the relatives should be told that the situation might later be improved by orthopedic measures. In some instances, braces may be made. In other instances, fixation of flail joints may assist in the use of the extremity. The most serious sequela is the difficulty that is associated with incontinence of the bladder and rectum. The patient should be instructed to eat food that will regulate the bowels, and thus, by the aid of an enema, manage the daily evacuation. The patient should be instructed to develop automatic control of the bladder. Evacuation often can be initiated by a massage of the lower part of the abdomen. Urinals may need to be worn continuously. Catheterization should be avoided whenever possible. In a few instances, presacral neurectomy has proved of value in regulating evacuation of the bowels and bladder. In still fewer instances, lumbar sympathectomy has proved of value in relieving the vasomotor changes of the lower extremities, by improving the circulation and preventing ulceration.

Report of Case

A single woman, aged twenty-two years, whose father was a physician, first came to the clinic on September 4, 1935. Her chief complaint was pain that was situated in the region of the sacrum. The pain had first been noted when the patient was thirteen years of age. The appearance of the pain had been intermittent. At times it had been so severe that it had compelled her to go to bed for two or three days. She did not complain of a true sciatica, but said that the pain did extend to the left knee. The pain had no relation to the time of day. The patient had been told that she had some abnormality of the sacrum and that she had a tumor in the pelvis. She had not had any other symptoms and the previous history was not significant. Examination disclosed tenderness in the left lower quadrant of the abdomen and a cystic mass that was situated in the hollow of the sacrum. Orthopedic examination revealed a marked lumbar lordosis, in addition to some tenderness over the lumbosacral region and over both sacro-iliac joints. Pelvic examination disclosed no abnormality except for the palpable mass previously mentioned. Examination of the blood and urine did not disclose any abnormality. Flocculation tests were negative. The roentgenograms revealed an absence of the lower half of the sacrum (Fig. 1). This was explained as a probable congenital aplasia. A neurologic examination failed to reveal any abnormality. The cystic tumor was found on rectal examination. A tentative diagnosis of a dermoid was made, but inasmuch as the patient was not urged to undergo operation at her initial visit to the clinic, she returned home without any surgical treatment.

Fig. 1. Malformation of the sacrum caused by a spina bifida cystica that originated in the sacral region and extended into the pelvis.

The patient returned on July 21, 1936, with instructions to consult me in view of my interest in the treatment of sacral tumors. She then informed us that after

she had left the clinic in September, 1935, she had continued to have sacral pain. This had been so severe that an exploratory laparotomy had been performed elsewhere in October, 1935. A retroperitoneal cystic mass had been found in the hollow of the sacrum, posterior to the rectum. The mass had not been opened or removed. The abdominal wound had been closed, without any surgical intervention. In May, 1936, the patient had spent six weeks in bed because of a persistent fever. For a few months previous to her second admission to the clinic, she complained of persistent paresthesias which had involved the left foot and leg. At times, the pain had extended upward along her left side, but had not involved the face. She did not complain of any objective loss of sensation. Her menstrual history did not indicate any abnormality. She was free from all other symptoms except constipation, which had been troublesome at times. She had not noted any dysuria or urinary frequency. At times, she thought that her abdomen had swelled, at least it had appeared to be tender in the left lower quadrant. Urinalysis did not reveal any abnormality. Additional roentgenologic examination of the spinal column revealed the same finding that previously had been observed. The proctoscopic examination revealed nothing abnormal in the rectum or sigmoid colon. The proctologist observed a large, soft cystic mass which was situated posterior to the rectum. The results of neurologic examination again were negative. The ophthalmologic examination likewise did not reveal any abnormality. At this time, it became my good fortune to see the patient in consultation. I reviewed the history and the findings and proceeded to carry out a digital examination of the rectum. I could palpate a soft fluctuant mass, about the size of a kittenball, situated posterior to the rectum in the hollow of the sacrum. The mass was definitely cystic and was less firm than a dermoid or a chordoma. However, both of these tumors had to be considered in the differential diagnosis. I ventured the opinion that we were probably dealing with a spina bifida cystica which had resulted from an anomalous development of the sacrum, and I advised an exploration of the sacrum through a laminectomy performed over the third and fourth sacral vertebral segments.

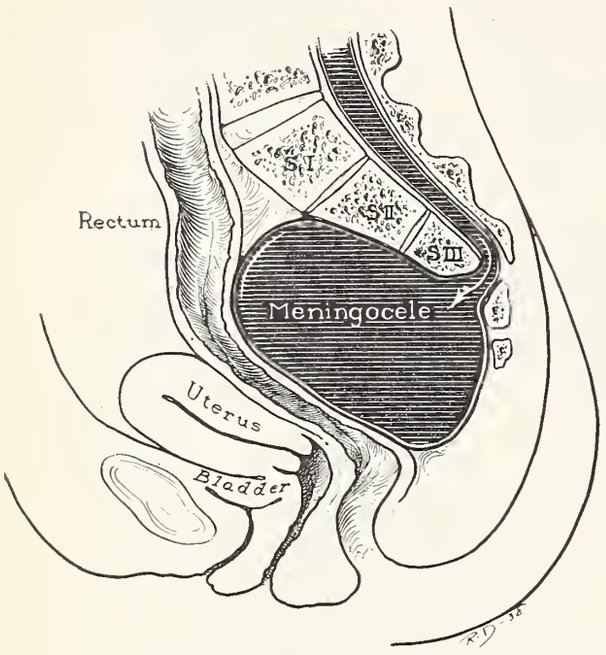

Fig. 2. Schematic illustration of a spina bifida cystica which was situated in the pelvis posterior to the rectum and in the retroperitoneal space.

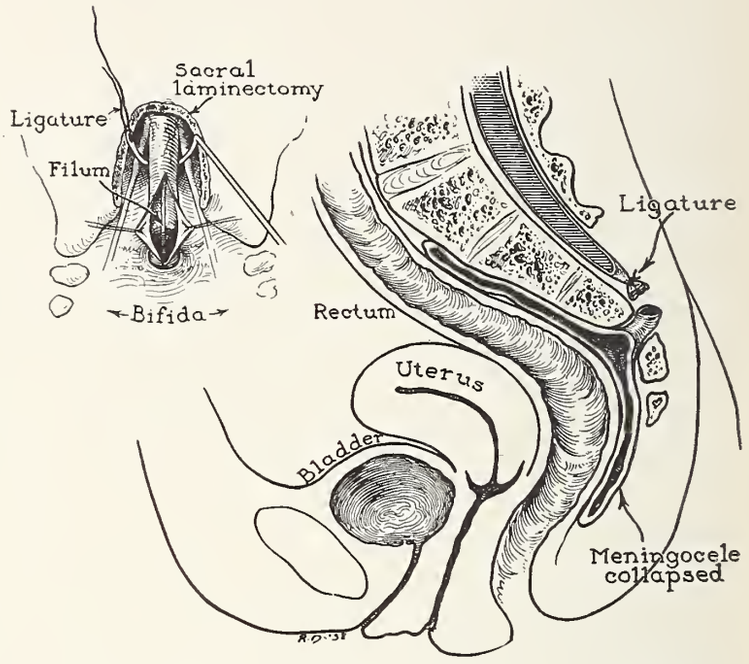

Fig. 3. Exposure of the caudal end of the sac through a small laminectomy wound, the resection and closure of the sac; this procedure permits the pelvic spina bifida cystica to drain into the soft tissues and collapse.

The laminectomy was performed opposite the third and fourth sacral segments of the vertebral column, through a dorsal midline incision. Upon exposing the dural sac, it was found to communicate with the pelvic mass. I opened this at the lower end of the incision and found that the cerebrospinal fluid in the subarachnoid space communicated with the fluid within the pelvic mass (Fig. 2). I then had to determine whether or not it contained nerve elements and found that the only structure that passed down through the dural sac into the pelvis was the filum terminale, which measured about 2 mm. in diameter. There were no nerve elements in the sac at this location. The nerve fibers had left the dural sac at a higher level.

The problem that confronted me was how to remove this sac, but it soon became apparent that it was impractical to attempt to remove the pelvic mass. Therefore, I decided to divide and ligate the dural tube, in the sacral canal, thus closing the caudad end (Fig. 3). This was accomplished by a purse-string suture and additional reinforcing ligatures. Upon exploring the pelvic mass I found that I could introduce a catheter for a distance of 5 inches. Subsequent exploration with the lighted retractor showed that the arachnoid lining of the dural sac was rather gray in appearance and free from any unusual masses. This convinced me that I was not dealing with a dermoid and that I was dealing with a spina bifida cystica which had extended an-

teriorly into the pelvis in the retroperitoneal space posterior to the rectum. After aspirating the cerebrospinal fluid in the pelvic portion of this sac, the walls were seen to collapse as a result of the increased intra-abdominal pressure. Thus, it occurred to me that if I left the distal portion of this sac open, it would automatically close itself and become adherent. Therefore, I proceeded to treat it in this manner. The wound was closed and the patient cared for very much as we care for other patients who have spina bifida. The patient remained under observation in the hospital for sixteen days and was dismissed from the clinic twenty-one days after the operation, which was on July 22, 1936. During her postoperative convalescence, it was necessary to catheterize her for the first five days. A postoperative neurologic examination did not furnish any additional information. The patient said that the pain was less severe than it had been but that she was still conscious of some paresthesia on the outer aspect of the left foot and around the saddle area of her buttock. A rectal examination on the day of her dismissal did not reveal any pelvic mass. It was impossible to palpate any sort of fullness; therefore, it was apparent that the mass had been thoroughly collapsed and had remained collapsed. It perhaps was held in place by the pelvic organs. In a letter dated April 3, 1937, the patient said that she had returned to work and was feeling normal.

Comment

Spina bifida usually appears through defects in the lamina but it has been known to appear laterally through the spinal canal and in a few instances has appeared anterior to the vertebral column. I have had occasion to observe a previous case in which the spina bifida was situated anterior to the sacral vertebræ. There had been a projection of a diverticulum of the spina bifida through the rectum. The patient was operated on for a rectal polyp and death resulted. The case reported is unique in that the mass was situated anterior to the sacrum as a result of a congenital anomaly in the anterior portion of the sacrum. The tumor and the bony erosion resembled a dermoid situated in this position. The tumor also resembled a chordoma which had extended into the pelvis, except that a chordoma is much firmer to palpation than was the mass in this case. The digital examination of this particular mass gave one the impression of a distended bladder except that the mass was situated on the opposite wall of the pelvis. The case is also unique because a cure was effected without removing the pelvic sac. This further confirms my opinion that a spina bifida cystica is a herniation of membranes through a spinal defect and that a cure can be effected without bone graft and without a folding in of the membranes; all that was necessary in this particular case was a division and a ligation of the dural-arachnoid tube at a place where the caudal sac normally would end.

CARCINOMA OF THE GALLBLADDER*

W. C. CARROLL, B.S., M.D., F.A.C.S.

Saint Paul, Minnesota

IT is not with the idea of offering anything new that this paper is written, but to call attention to a condition which I think has not been given enough thought and consideration in the care of cases with gallbladder disease.

As the pendulum of surgical opinion swings from conservatism to radicalism, and back again, it is often difficult to establish the accepted course to pursue. In April, 1911, W. J. Mayo wrote, "Ten years ago, we heard a great deal about "innocent gallstones," which means that gallstones existed without symptoms and that their presence was not suspected until postmortem examination brought them to light. We can not now escape the conviction that gallstones did cause symptoms and that we, as diagnosticians, and not the gallstones, were innocent." Andrews would take serious exception to the above quotation, for he recently said, "I think the operation on silent stones is a scandal." The question I would raise at this time is, how often do we see "silent stones"? A careful history taken after we know that a certain patient has stones will usually elicit the fact that symptoms were present even though they were mild and entirely disregarded by the patient. It certainly is not necessary to have colics to have symptoms of gallbladder disease. As we have hypersensitive patients, we also have hyposensitive ones. The latter will uncomplainingly carry their troubles, and conceal symptoms which will be uncovered only by the most searching questioning.

Carcinoma of the gallbladder is of sufficient frequency to make it a factor of serious consideration when we must pass judgment on a case of gallstones. The exact percentage of malignancy is difficult to evaluate as many cases both of gallstones and malignancy go undiagnosed. It is usually ranked sixth in frequency of malignancy of the digestive organs. Surgical experience in various large clinics in this country place the percentage from 1 to 2.5 per cent of all operations on the gallbladder. Collected statistics from cases reported by Wilkie, Deaver, Smith, Judd and Gray, Miller, French, Sherrill and McCarty show that there were 393 carcinomas in 35,054 operations, an incidence of 1.12 per cent. Boyce and McFetridge[2] in the *International Surgical Digest*, Critique Section, state, "Looking at the facts from another angle a certain proportion of patients with gallstones develop cancer. Leutz, in 557 cases of cholelithiasis, found that malignancy developed in 5.1 per cent of women over thirty-nine years of age, and in 4.3 per cent of both sexes. Rolleston found the incidence of malignancy following cholelithiasis to be 4.5 per cent; Moynihan 5 per cent; Ridel 7 to 8 per cent; Graham 8.6 per cent and Schroeder 14 per cent. In five of the eighty-four cases reported by Magonn and Renshaw from the Mayo Clinic in 1921, the malignancy had developed at the site of a previous cholecystostomy for stones, and similar cases have been put on record by F. K. Smith, Mayo Robson, Knapp, Lett and others."[6] Judd has stated that those who develop malignancy of the gallbladder have had stones. Clinicians who will not accept this statement in its entirety must admit that cancer will not develop in a healthy gallbladder. An argument against this theory is the fact that experimentors have been unable to produce cancer in animals by the introduction of gallstones or other foreign bodies into the gallbladder. Barlow made the suggestion that calculi taken from malignant gallbladders are radio-active. Petrac and Krotkina used nineteen guinea pigs and inserted small radium tubes in twelve, and produced malignancy in two, after 136 and 158 weeks, respectively. However, two of the controls, in which only sterile glass capsules were inserted, also developed malignancy with metastasis at the end of sixty-six and 166 weeks. Other observers feel that a chemical factor either independent or in association with stones is responsible for the new growths. However, if we recognize the chronic irritation theory, there seems to be a causal relationship between stones and malignancy. As regards sex distribution, almost three-fourths of the reported cases have been in women, somewhat higher than the average distribution of benign lesions. There are records of carcinoma of the gallbladder in all decades, over the age of

*Read before the Saint Paul Surgical Society, February 10, 1938.

twenty, but the majority fall between the ages of fifty to sixty-five.

Papillomata are of such frequent occurrence that one would hardly believe that there is a relationship between them and malignancy. Nevertheless, cases have been observed where there are areas of epithelial proliferation extending through the muscle wall and some specimens show a close resemblance to papillary carcinoma. If there is at least a possible relation between these apparently benign looking, wart-like growths and the development of cancer, we then must look upon such a gallbladder as being better out, and not just regard it as many would, along with the strawberry type, as a metabolic disturbance incapable of causing any damage.

Pathology.—There are four generally recognized types of carcinoma of the gallbladder, and they can usually be differentiated by the naked eye: (1) scirrhous; (2) papillary; (3) mucoid-colloid; (4) squamous cell (epithelioma).

1. The scirrhous type is the most common, starting as a small infiltrating tumor, or thickening, which is at times overlooked in its early stage, but in its later development involves the whole gallbladder, contracting down on the stones so as to make it difficult at times to identify the organ itself. Microscopically, it is that of an adenocarcinoma It extends very early into the liver and the glands along the common duct.

2. The papillary type originates at the fundus or neck of the bladder and grows out into the lumen as a coarse villous or solid fungating mass. It is often associated with empyema as it early obliterates the cystic duct. Microscopically, it is that of a columnar cell adenocarcinoma.

3. The mucoid, or colloid type, is bulky and soft, and can be recognized by its jelly-like appearance. Microscopically, there are trabaculæ of fibrous tissue with large spaces of pseudomucin. Tumor cells are few and are found singly or in small groups. These cells contain small drops of mucin which enlarge, bursting and discharging their contents into the connective tissue.

4. The squamous type is the least common, and can as a rule only be differentiated microscopically. It is seen as an epithelioma made up of cells of squamous type with prickle cells, and only occasionally do epithelial pearls occur. The usual explanation of a squamous cell type in the gallbladder is that it arises from a previous leukoplacia which has been caused by irritation from pre-existing gallbladder disease.

Dissemination of any type is usually by local excision, distant metastases being encountered at post mortem. The lungs are involved in 10 per cent of the cases. The liver, on account of its intimate association and direct blood and lymphatic supply, is involved very early. In the right lobe, there frequently forms a large hard mass, while, at times, multiple nodules are found throughout the entire organ, which becomes greatly enlarged. The regional lymph nodes also are the seat of early metastases. The node by the cystic duct enlarges, blocking both the duct and artery, resulting at times in hydrops or more frequently empyema. The carcinomatous bladder is more subject to empyema than others. From this first gland, the others along the common duct and retroperitoneally become invaded.

Clinical Features.—Apparently, as yet, we have no signs by which an exact diagnosis of carcinoma of the gallbladder can be made in its early stage. The usual symptoms of gallbladder disease are present in the well taken history, varying in degree from those of a severe colic to the mildest indigestion. In two recently observed cases, there was a distinct change in the character and degree of the distress, the discomfort becoming more continuous and unrelated to food intake. The colic present earlier in the course of the disease in these cases had given way to more constant pain, which was the one symptom that finally made the patients consent to operation. Nausea, vomiting, anorexia, weight loss and jaundice, and finally cachexia, with or without signs of emypema of the gallbladder, are symptoms which appear as the disease advances. Jaundice may be an early symptom if the glands become involved and cause pressure on the common duct. The earlier the jaundice occurs, the sooner death will follow. Diarrhea and extreme weight loss have been noted in certain cases before any symptoms of biliary disease have attracted attention.

Various authors have tried to classify the disease according to symptoms but the overlapping and bizarre complaints make this extremely difficult. If we wait until a tumor mass is felt before advising operation, we will find that the patient is well beyond any surgical relief. This is the stage in which most of the patients are seen.

Cholecystography might be of possible value in early diagnosis, as Kirklin has suggested that a filling defect more than 2 cm. in diameter with an irregular border should arouse suspicion of malignancy. The necessity of well taken films and proper interpretation, of course, is very obvious. Boyce and McFetridge further observed in this review: "The only solution of the problem seems to be the constant recollection that malignancy of the gallbladder is a definite possibility in all cases of persistent retention of bile and the consideration of malignancy as a possible diagnosis of all cases of cholecystitis or cholelithiasis in individuals over forty, or even younger. If the possibility of its occurrence is not constantly borne in mind, the diagnosis will always be missed."

Treatment.—At the present time, the majority of patients with carcinoma of the gallbladder are seen too late for radical removal. Any operation, except in the very early cases, usually renders the patient more uncomfortable than before. If a cholecystectomy is at all feasible, it should be done and the lymph nodes along the cystic duct removed. The electrosurgical unit is of value for this operation as a portion of the liver about the gallbladder fossa where direct extension takes place should be removed. Gastroenterostomy may, at times, be indicated to relieve the pyloric obstruction. The immediate mortality, especially in the jaundiced cases, is usually very high, and those that survive operation, succumb in a few months. Every series on record has the same discouraging picture. Webber, at the Mayo Clinic, studied thirty cases according to Broders index, correlating the clinical findings with the microscopic picture. He found that in the groups graded I and II, palpable tumors were present in two cases, while there were twelve in Grades III and IV. Furthermore, the duration of life in Grades I and II was thirty-four months against 4.8 months for those of Groups III and IV.

Early operation in gall bladder disease will, undoubtedly, prevent the occurrence of carcinoma, as well as ward off many of the other possible complications. Heyd, former president of the American Medical Association, writes editorially, "Preventative medical thought and wise judicious surgery would suggest the early removal of chronically infected gallbladder and not delay until the accident of infection initiates a fulminating acute cholecystitis," and further he states, "Teachers of surgery who lend their prestige and give support to a policy of waiting, provide authority for timid surgeons, inexperienced operators and procrastinating practitioners."

Having personally observed patients with gallstones go through long periods of watchful waiting, hoping that nothing very serious will develop except an occasional colic, and then later seeing them with the more serious complications of damage to liver and pancreas, empyema, and, in a few, malignancy, I can wholeheartedly subscribe to Dr. Mayo's saying: "Innocent gallstones —a myth!" I believe the mortality in gallbladder operations performed before the development of complications should, in competent hands, be less than the incidence of malignancy alone. Individual case reports are of very little value as the usual picture is well known, but upon seeing a small but increasing number of these cases, which might have been avoided but for procrastination on the part of either patients or their physicians, I feel that too little attention has been called to this usually avoidable tragedy.

RECURRENT "TROPICAL" LYMPHANGITIS*

With Report of a Case

RUDOLPH C. LOGEFEIL, M.S., M.D., and ROY A. HOFFMAN, M.D.
Minneapolis, Minnesota

SIMPLE acute lymphangitis is a rather common affection accompanying infected wounds of the hands and feet, and is usually due to infection from streptococci, less often to staphylococci, gonococci, or pneumococci. The bacteria may enter the lymph vessel directly from the infected wound, or pass through the wall of the vessel from without. However, inflammation of the lymphatics may occur without a primary focus of infection. It may occur during the course of acute infectious diseases, herpes, and especially erysipelas. Such chronic infectious diseases as gonorrhea, syphilis, tuberculosis and bubonic plague may show lymphangitis. Other forms occur after roentgen irradiation, sunburn, poison ivy and insect bites.

Osler[5] offers a pathologic classification of acute lymphangitis as follows: simple, purulent, and proliferative. The chief features of the simple form are hyperemia, edema and infiltration of the vessel walls and perilymphatic tissue with a resulting thickening which may become necrotic or proliferative. The condition returns to normal if the existing cause is removed. Otherwise, it may lead to a chronic process.

The purulent form shows more thickening of the wall, the lumen becomes filled with pus or a fibrino-purulent mass which, between the valves, gives a beaded appearance. Abscesses may form along the course of the lymph vessel or in the regional lymph nodes, and septicopyemia may result.

The acute proliferative type occurs chiefly in gonorrhea, the principal feature being a marked perilymphangitis.

Chronic or recurrent lymphangitis results in a partial or complete obliteration of the lymph vessel due to hypertrophic changes resulting from a proliferation and induration of the connective tissue of the vessel wall and surrounding tissues. When affecting an extremity, chronic edema or elephantiasis are the most important clinicial features.

Goeckerman,[1] in discussing recurrent lymphangitis, distinguishes between lymph-edema and solid edema, applying the former term to stasis of lymph resulting from mechanical obstruction like that following radical amputation of the breast without infection, while restricting the term solid edema to the end-process of recurrent lymphangitis.

Recurrent lymphangitis may be defined as repeated attacks of simple acute lymphangitis, due to an inflammatory process in the cutaneous lymphatic vessels caused by the streptococcus hemolyticus. The involved part shows a well defined area of redness, swelling and local pain, which spreads by direct continuity and is associated with general febrile symptoms. Suppuration may occur when the subcutaneous tissues are involved, and the whole process turns into the suppurative form. It occurs in temperate climates during the hot months, but is much more common in the tropics or sub-tropics, where it is called recurrent tropical lymphangitis. This is probably due to the fact that profuse sweating, dehydration and irritation of the skin predisposes it to infection. Although erysipelas affects the skin somewhat similarly it is more frequent during the colder months of the year, probably due to the increased frequency of upper respiratory infections. Also meteorological studies have shown that the frequency of erysipelas corresponds with an increase of humidity in the air. Other streptococcic infections, such as scarlet fever and rheumatic heart diseases, are common in temperate and cold climates, but scarce in California, and almost unknown in Puerto Rico.

My case is that of a white male, thirty-one years of age, single, who for the past eleven years has had recurrent attacks of inflammation of the lymphatics in the lower extremities, followed by edema.

He was born in Kentucky in 1906 and lived there for four years, before moving to Ohio. During early childhood he suffered no other illnesses than an attack of typhoid fever at the age of two and a second attack at the age

*Read before the meeting of the Minnesota Society of Internal Medicine, May, 1937.

of eleven. At twelve he was seriously ill with an acute bronchitis and an associated jaundice which persisted for a period of five weeks. A tonsillectomy was performed at the age of sixteen. There was no history of venereal diseases. His father and mother are living and well. His grandmother, mother, and brother have had acute rheumatic attacks, accompanied by high fever, and a moderate amount of swelling and pain in the hands and feet, lasting about a week.

The patient was apparently in good health until August of 1925, at which time he had a blister on his left heel which became secondarily infected. This condition cleared up in about a week under treatment, but recurred a month later and necessitated hospitalization for a ten day period. At the end of that time there was no further evidence of infection and he remained in good health until August, 1926, when he sustained an abrasion to the skin of the lower left leg. Within twelve hours he had a severe chill followed by a high fever and the typical clinical picture of an acute lymphangitis and lymphadenitis of the left leg and groin. The treatment consisted chiefly of rest, elevation of the limb, and application of local wet packs. The infection gradually subsided and within five weeks he was able to return to work.

In July, 1927, during a spell of very hot weather, without any evidence of external injury, he developed pain in both groins with tender, swollen glands, and evidence of lymphangitis of both legs, accompanied by high fever and the same constitutional symptoms as before. This attack subsided in ten days, after which he resumed his work.

Similar attacks occurred the next three summers, always during spells of hot weather, with complete recovery from each attack, except that there was a persistent gradual increase in the edema of both lower legs. He had no recurrence during the summer of 1931, all of which time he spent in Duluth, Minnesota. From 1931 to 1936 he had somewhat milder recurrences each summer, the most severe attack occurring in August, 1936, at which time he first came under my observation. About two weeks before this attack he came to my office complaining of edema of both lower legs below the knees.

Physical examination at that time was entirely negative except for edema of the lower extremities and an epidermophytosis infection between the toes, commonly known as "athlete's foot." Tests for patency of the internal veins of both legs proved them to be normal. Urinalysis showed an occasional cast; P.S.P. 77 per cent in two hours; hemoglobin 83 per cent; rbc. 4,-170,000, wbc. 8600, P.M.N. Neut. 69 per cent, P.M.N. Eos. 4 per cent, large mono. 1 per cent, large and small lympho. 26 per cent; blood urea 15.6 mg. per 100 c.c. blood; Wassermann negative; basal metabolic rate minus 3.

A sedimentation rate of 55 mm. in 45 minutes was the only finding of consequence in any of the blood tests.

Six days later, during a spell of very hot weather, he suddenly had a severe chill, followed by a temperature of 105, and became acutely ill. Both lower legs were swollen, rather tender, with glandular enlargement of both inguinal regions. These glands were acutely inflamed, tender to touch, and they were more numerous and larger on the left side. He was sent to the Swedish Hospital, where laboratory tests revealed the usual febrile urinary findings, white blood count 30,500; differential count of 91 per cent P.M.N.; 5 per cent large Mono., 3 per cent small Mono., and 1 per cent transitional cells. The blood culture, Wassermann and tests for tularemia mellitensis and typhoid were negative.

The patient's temperature was 104.2 degrees on admission to the hospital and increased to 105.6 shortly afterward. He was irrational at this time. A septic temperature curve persisted for the next five days, fluctuating between 100 and 103 degrees, and gradually descending to normal on the sixth day.

The most interesting finding was the appearance of the extremities. There was an area of redness and a rash beginning at the ankle and spreading upward. The skin became hot, swollen and glistening; the margin of the rash was sharply demarcated but not palpably raised. As the rash advanced, the center of the affected area became somewhat pale and edematous. It spread from below upward by direct extension, and extended to the knee joints or slightly above. However, a red streak extended up along the cords of the lymphatics to the regional lymphatic glands in the groins. As the temperature began to fall and the general con-

dition of the patient improved, the rash concurrently began to fade and practically disappeared when the temperature was normal. However, the limbs remained swollen and painful for many days afterward, and there was slight desquamation of the skin on the affected parts. The edema persisted and continued to remain increased over that present before the attack.

The above description is typical of all his attacks, but some, however, were not as severe as this one. Except for the persistent edema the patient remained well until August, 1937, when, during a spell of very hot weather, he had a similar but milder attack while working in North Dakota. This attack lasted about eight days and then left him again with a slight increase in the edema of the extremities. On close quizzing I found he had noted peeling between the toes practically every summer, and had treated this during one previous summer, following an attack. Altogether the patient has had fifteen attacks. Several summers he has had two attacks, and in 1930 had three attacks. The only summer he was free from it was in 1931 when he spent the entire summer in cool Duluth, Minnesota. In 1929 he received vaccine from a gland removed from the groin by Dr. Duff, but apparently this was of no help. The microscopic examination of this gland showed only chronic inflammation. He suffered no complications in any of the attacks except a persistent pachyderma.

I feel that my case is similar to those reported by Janero Suarez[7] under the title "Recurrent Tropical Lymphangitis." This disease occurs quite frequently in the southern part of the United States and is endemic in Puerto Rico and other sub-tropical countries. It attacks chiefly young people, more commonly females, who are most susceptible during menstruation and the puerperium. Over 90 per cent of Suarez's series occurred in the lower extremities, 81 per cent being limited to one leg. When present in both legs, one is usually more affected than the other. It gives no immunity to the patient; on the contrary, one attack predisposes to another. Recurrences may take place frequently or may be months or years apart, and are most common between the ages of twenty and forty. However, it has been noted that a severe attack is usually followed by a long remission. Patients have been known to have sustained fifty or sixty attacks, often occurring regularly, every four to six weeks. Chronic edema or pachyderma results in a majority of the cases. Suarez believes the mechanical lymphatic obstruction or bacterial infection is in itself capable of producing elephantiasis. Mates[4] and Grace[2] believe that bacterial infection plays an essential etiological role in the pathology of elephantiasis. Drinker[3] and his associates have demonstrated in remarkable experiments on large police dogs that spontaneous attacks of lymphangitis occurred where lymphedema or experimental elephantiasis was produced by total destruction of the lymphatics in the hind legs. Hemolytic streptococci were cultured from the tissues of the affected leg, which could be transferred to other dogs, but only in limbs previously operated upon. In view of the fact that humans are more susceptible to streptococcal disease than canines, previous obstruction of the lymphatics is not essential for the production of acute lymphangitis, but, when present, predisposes to future attacks.

In Suarez's[7] series of 139 cases, ninety-one showed a definite focus of infection, 72 per cent of which were epidermophytosis interdigitalis. Removal of this infection was usually followed by cessation of attacks. One can usually get a history of focal infection or injury preceding the first attack. Occasionally cases occur in which no local lesion can be found. Suarez had two cases of this kind. They were classified as allergic. The redness, heat, edema and fibrosis probably represent "an allergic phenomenon to a protein fraction of the streptococcus or its toxin."

The symptoms and physical findings during a typical attack in my case correspond well with those described in Suarez's series. Incubation period was two to three days, while relapses occurred in 4 per cent of his cases. Chronic lymphedema and subcutaneous abscesses are the most common complications.

Otero and Lebron[6] demonstrated the presence of agglutinins against streptococci in practically every case of recurrent tropical lymphangitis. They give a positive allergic reaction to streptococcus filtrate, which disappears during the febrile stage. However, they found a definite increase in the antistreptolysin content of the blood, during an attack. They also believe that

acute attacks are preceded by hemolytic streptococcus infections.

The presence of an area of redness with a well-defined margin, spread by direct continuity, pain and the accompaniment of constitutional symptoms, distinguishes recurrent lymphangitis from other erythematous lesions. Abscesses, cellulitis and thrombophlebitis may at times be confused.

Prognosis is very favorable, no deaths having been reported. Morbidity is great, however, due to recurring attacks. Disability produced by the elephantiasis is of considerable importance.

Treatment consists of the following:

1. Removal of any possible focus of infection.
2. Proper care of the feet, especially during hot weather, with elimination of any possible epidermophyton infection.
3. Goeckerman[2] has had gratifying results in the early stages in seventeen cases from the use of foreign protein given intravenously and filtered roentgen rays applied locally.
4. Moving to a cool climate during the hot summer months is good prophylactic treatment.
5. The treatment of the elephantiasis is a difficult and lengthy problem.

Conclusions

1. I believe this case represents a definite clinical entity, occurring sporadically in this country, more commonly in the south, but which is endemic in tropical countries and described under the title of recurrent tropical lymphangitis.
2. It occurs only in hot weather.
3. An infective lesion or abrasion can usually be found, especially in the initial or early attacks. The initial attack predisposes the patient to further attacks. Severe attacks may produce some temporary immunity.
4. Injury to the lymphatics of the extremity with resulting chronic obstruction and an acquired allergy to hemolytic streptococcus, plus hot weather, may cause recurrences without infection or injury to the skin. This has been borne out by clinical and experimental observations.
5. Treatment, except prophylactic, has been unsatisfactory.

INTESTINAL OBSTRUCTION DUE TO CALCIFIED MESENTERIC GLANDS

JOHN M. CULLIGAN, M.D.
Saint Paul, Minnesota

IN ROUTINE roentgenograms of the abdomen shadows of calcified mesenteric glands are a rather common finding. In the large majority of cases they are more or less of academic interest and surgical interference is not indicated. It is interesting to speculate upon their etiology and pathogenesis.

The primary causative agent is of course the tubercle bacillus. The human and the bovine types have been isolated from the glands. The human type is isolated from the glands of patients with tuberculosis elsewhere in the body whereas the bovine type is isolated usually from the glands of children who have ingested milk from tuberculous cows. Approximately 60 per cent of the cases are of the latter type.

The clinical course of the disease is variable. In the majority of patients no definite history of symptoms which might lead one to suspect the disease can be elicited. The disease is discovered late when a roentgenogram of the abdomen is made. The roentgenographic findings, when the diagnosis is made this way, are typical shadows of calcified glands usually having characteristic features. They present moth-eaten shadows of different density varying in diameter

Fig. 1. Roentgenogram showing a large mesenteric gland in the right lower quadrant of the abdomen, measuring 8 x 5 centimeters. Gaseous distention of the small bowel can also be seen.

Fig. 2. Roentgenogram showing a small mesenteric gland in the right lower quadrant of the abdomen measuring 2 x 2 centimeters. The degree of obstruction may be demonstrated by the dilated loops of small bowel.

Fig. 3. Roentgenogram showing two large and multiple small shadows of calcified mesenteric glands. The largest measures 4 x 3 centimeters. No dilatation of the bowel is evident.

from one to five or six centimeters or more. They may be found any place in the abdomen but are usually located in the region of the umbilicus, probably a little more often on the right side.

Early in the disease an entirely different picture may be seen. The so-called acute type may give rise to definite clinical symptoms and signs. These are usually pain, colicky in character, associated with nausea and vomiting and abdominal tenderness in the region of the umbilicus or over the right lower quadrant of the abdomen. Exploration at this time will reveal enlarged caseating nodes in the mesentery.

Subacute types may be characterized by indefinite and vague abdominal complaints associated with pallor, weakness, and occasional attacks of slight fever. At times, the glands may be palpated.

Recently, we have observed three cases which were of the asymptomatic chronic type until obstruction of the bowel developed. From the size of the glands found at operation and because of their hard calcified nature, it was apparent that they had been present for many years, but the patients had had no symptoms referable to them. In two of the three patients, complete obstruction of the bowel was produced in the first attack, and in one chronic recurring partial obstruction was produced. The diagnoses were made from the findings of obstruction and the presence of shadows in the roentgenograms suggestive of calcified mesenteric glands.

Case 1.—A seventy-one-year-old woman was seized by severe abdominal cramps and abdominal distention. Within twelve hours vomiting occurred. This persisted. The patient was unable to defecate or pass flatus even with enemata. A roentgenogram (Fig. 1) revealed a large calcified shadow suggestive of a mesenteric gland. At operation through a right rectus incision, the entire small bowel was found injected and distended. The point of obstruction was in the right lower quadrant involving the ileum about twelve inches above the ileocecal valve. A large calcified gland was present in the mesentery close to the bowel. Cicatrization formed adjacent to it completely obstructed the bowel. The gland was excised, a few adhesions cut, and the collapsed bowel distended as the gas passed on. The patient made an uneventful recovery.

Three months later, she again presented herself with obstruction of the bowel. This time, it was due to a strangulated right inguinal hernia. This was freed and the hernia repaired. She again had an uneventful convalescence.

Case 2.—A forty-six-year-old married woman was awakened at two o'clock in the morning by severe abdominal cramps. She slept very little during the remainder of the night. A hypodermic injection of morphine was administered at nine a. m. The patient was first seen at eight p. m. Paroxysms of pain were present and visible peristalsis could be seen. She obtained slight relief from enemata. A roentgenogram of the abdomen (Fig. 2) showed distention of the bowel and a shadow suggestive of a calcified mesenteric gland. Exploration, through a right rectus incision, revealed a greatly distended upper ileum. An obstructing band at the site of a calcified mesenteric gland encircled the bowel. This was cut and gas escaped into the collapsed bowel beyond the obstruction. The gland was excised. The patient made an uneventful convalescence.

Case 3.—A twenty-five-year-old single woman had had an appendectomy five years previous to the time I saw her. She complained of intermittent attacks of abdominal pain associated with abdominal distention. This pain could be relieved by enemata. Roentgenograms of the abdomen revealed two shadows of calcified mesenteric glands (Fig. 3). At operation, a constricting band bound the bowel to one of the glands. This was cut and the glands excised. Convalescence was uneventful and there has been no return of pain.

BROMIDES, THEIR USE AND ABUSE*

GORDON R. KAMMAN, M.D., F.A.C.P.
Instructor in Nervous and Mental Diseases, University of Minnesota,
Saint Paul, Minnesota

WITH the gradual elimination of industrial hazards, with increased efficiency in the control of epidemic diseases, and with the speeding up of modern living conditions, there has been in recent years a great increase in the number of functional nervous diseases afflicting the general population of our country. Man formerly used his skeletal muscles to subdue his natural enemies and to convert natural resources into the essentials of life. In modern times the burden has been lifted from our physical bodies and a great load thrown upon our psychological and emotional mechanisms. As a result of this change, the administration of hypnotics and sedatives which act upon the nervous system represents one of the most common procedures in modern medical practice. Millions of dollars are spent annually for the purchase of these drugs, and as a result of carelessness on the part of the medical profession they are frequently used by the laity without medical supervision. These drugs effect no cure. Their function is merely to mitigate; to intercede between man and his environment; to serve as a buffer which absorbs part of the constant and unrelenting barrage of stimuli to which man is subjected. There is scarcely any group of drugs more freely employed than sedatives and hypnotics, and prominent in this group are the salts of bromine. Inasmuch as the functional conditions in which these drugs are given are usually prolonged states, cumulation often occurs; but because of their extreme diversity, the symptoms of bromide intoxication are frequently missed. The complex of the busy doctor, plus the neurotic patient, plus the "salty medicine," is a common one; and the oft-repeated statement, usually delivered over the telephone, "keep taking that salty medicine," many times does much more harm than good. There are times when I suspect that a physician's skill as a psychotherapist stands in inverse proportion to the amount of bromide that he prescribes.

True, the salts of bromine are too valuable as therapeutic agents for us to decry their use, and it would be no more logical merely on account of a few cases of bromide poisoning to condemn them as a whole than it would be to condemn digitalis because of the occasional occurrence of digitalis poisoning. In my experience, however, bromide intoxication seems to be occurring with such increasing frequency that, in spite of numerous contributions already made to the literature on the subject, it seems justifiable again to call the attention of physicians to certain dangers inherent in the use of bromides, and to point out specific methods for the diagnosis and treatment of bromide intoxication. Credit should be given to Wuth[17] for awakening interest in bromide intoxication and for publishing in 1927 a simple laboratory method for the quantitative estimation of the bromide content of blood serum.

The purpose of this paper is to call attention to the fact that bromides even in therapeutic doses may produce mental symptoms in susceptible individuals. These symptoms range from a mild clouding of consciousness to an active delirium, and from mental depression to stupor and coma. In recent years, I have observed a number of patients who have manifested symptoms of bromide intoxication which have slowly cleared up after withdrawal of the drug. These have usually been elderly individuals with varying degrees of arteriosclerosis, or cardiac and renal insufficiency; or younger persons who could not or would not take sufficient food, or were anemic and undernourished. It is probable that some of the exacerbations of mental symptoms and of the psychoses which occur from time to time in patients under our care are due to drug intoxication from our therapeutic efforts rather than to the underlying conditions which we are trying to treat. One has frequently seen acutely disturbed psychotics in full restraints and requiring feeding by nasal tube become quiet and coöperative within forty-eight hours after discontinuance of a bromide ration of 45 gr. (3.0 gm.) a day.

Incidence

The first case of bromide intoxication was reported by Huette[3] in 1850, and for many years following this, reports of the condition were very infrequent. With the shift in preponderance

*Thesis presented before the Minnesota Academy of Medicine, October 13, 1937.

from infectious and physical diseases to neuropsychiatric disorders, the use of the salts of bromine as therapeutic agents has increased and more and more cases have been reported in recent medical literature. Apparently, the incidence of bromide intoxication and bromide delirium is higher than one ordinarily suspects. Among 505 admissions to the state hospital at Harrisburg, Pa., during the two years beginning June 1, 1931,[6] there were fifteen unquestionable cases of bromide psychosis. Among 238 admissions to Johns Hopkins hospital over a six month period[17] there were twenty cases of bromide intoxication, an incidence of 8.4 per cent. Among 1,000 consecutive patients admitted to the Colorado psychopathic hospital, forty-four showed an excess of bromide in the blood, and in seventeen (1.7 per cent) the mental symptoms were due solely to bromism.[13] During 1935, 2.7 per cent of the patients admitted to the Psychiatric Clinic at the New Haven Hospital in Connecticut showed definite signs of bromide intoxication.[7]

Pharmacology[14]

The effects of the bromine ion are largely confined to the central nervous system. Whatever other effects it produces are relatively insignificant and may be considered as secondary to those on the central nervous system. The slowing of respiration, the reduction of body temperature, and the slowing of all the physical processes may be attributed to lessened movement and consequent decreased heat production incident to the depressing action upon the central nervous system. All parts of the nervous system are affected, but the higher cortical centers seem to be most susceptible to the drug. Thomas[11] working with rabbits found that the amount of bromide absorbed by various portions of the central nervous system depends, in part, upon the water content of its various tissues. By feeding different rabbits known quantities of bromide, Thomas was able to show that the bromide content of the gray matter of the central nervous system was about 150 per cent that of the white matter when the content was calculated in milli-equivalents of bromide per gram of dry weight. Bastido[1] has shown that in bromidized dogs stimulation of the motor areas does not produce convulsions. In humans under the influence of bromide, the higher intellectual centers are retarded and the reaction time is prolonged. There also is a depressing effect on the spinal cord and the spinal reflexes are inhibited. Ordinary doses of bromide have no effect on the circulation, but larger doses depress the heart and vasoconstrictor centers, lessening arterial tension.[9]

When ingested, bromides are readily absorbed from the stomach and appear in the urine a few minutes later. However, elimination takes place very slowly, and after a single does of bromide by mouth, although the drug may be detected in the urine in a few minutes, it also may still be found in the urine as long as twenty days afterward. Bearing this in mind one should not have any difficulty in appreciating the cumulative effect of oft repeated doses of bromide over a long period of time.

Landheimer, in 1901, was the first to recognize the important influence of the intake of chlorides upon the retention of bromides. Bromides are not excreted by the kidneys as rapidly as chlorides but they tend to displace the latter in the blood and other body fluids. The displaced chlorides are excreted by the kidneys in preference to the bromides. This permits an accumulation of the bromides with consequent lowering of the chloride content of the body. A diminished chloride intake (insufficient food, or a nasal feeding formula containing insufficient chloride, *vide infra*) increases the risk of bromide intoxication. Conversely, an increased chloride intake facilitates the elimination of bromide. When 25 to 30 per cent of the blood chloride is replaced by bromide, symptoms of intoxication usually appear. Bennoulli states that a replacement of more than 40 per cent of the chlorides in the blood by bromide is fatal. It can be seen, therefore, that when a patient is receiving bromide medication, his chloride intake is of paramount importance. In order to maintain the chloride-bromide equilibrium, according to Rylan,[8] the chloride intake should be four times the bromide intake. If the bromide intake equals the chloride intake, intoxication will occur in about three weeks. According to Wuth[17] the average hospital patient takes about 7.4 gm. chloride in twenty-four hours. At Mounds Park Sanitarium, in St. Paul, the average daily diet contains 12 gm. of chloride exclusive of what the patient adds to his food after it is served to him. This amount of chloride is enough to balance 3 gm. (45 grains) of bromide per twenty-four hours, provided the

patient eats all of his food. However, the standard nasal feedings, for which there are several formulæ, contain an average of 3 gm. of chloride per twenty-four-hour ration.[13] The average twenty-four-hour bromide dose for a neuropsychiatric patient being 3 gm. (15 gr. three times a day) it can readily be seen that if Rylan's computations are correct, patients on nasal feeding and regular bromide medication should show signs of bromide intoxication in about three weeks. In my experience this has frequently been the case.

The question has frequently been raised as to whether the effect of bromide is dependent primarily upon the excess of bromide itself or upon consequent diminution of the chlorides. The effect of a single dose of bromide is too rapid for chloride diminution to be a factor. Furthermore, it is possible to narcotize dogs with bromide before diminution of chlorides has had time to play any conspicuous part.[14]

Symptoms of Bromide Intoxication

The clinical picture of bromide intoxication is extremely variable, and according to Katzenelbogen[14] and his associates, the only accurate method of establishing the diagnosis is the determination of an excess amount of bromide in the blood. While it is true that there are no pathognomonic symptoms of bromide delirium, and while it is also true that one encounters many cases in which the cutaneous manifestations of brominism are absent, I believe that it is possible to separate the types of brominism into two large clinical groups: simple bromide intoxication or depression, and bromide delirium or psychosis.

Simple bromide intoxication or depression consists of a state of mental sluggishness in which the patient thinks and acts with great difficulty, but is oriented and doesn't exhibit delusions or hallucinations. He is dull, stupid, and indifferent. His face is pale, expressionless, and may or may not show a rash. The eyes are heavy lidded, the expression staring, and the patient complains of headache. All the mental and physical reactions are retarded, memory may be impaired for recent events, and the gait is ataxic. There is anorexia, flatulence, nausea, and constipation. All tendon reflexes, as well as the corneal and pharyngeal reflexes, are reduced or absent. The pulse may be rapid and the temperature somewhat elevated.

Bromide delirium or psychosis, as has been stated before, is not an independent nosological entity. It is like any other toxic delirium and belongs to what Adolph Meyer calls the dysergasic state. The dysergasic state embraces all the exogenous psychoses, acute delirious manias, toxic-infectious psychoses, infective-exhaustive psychoses, deliria of fever, and drug deliria described by other authors. In addition to disintegration of function at the biological level (ataxia, tremor, slurring speech, et cetera) there is always dysfunction at the psycho-biologic level. Consciousness is clouded to a degree varying from patient to patient, and often from one minute to the next in the same person. There almost always is disorientation to some degree in all spheres, and the outstanding feature is great distractability. Thinking is incoherent, and there may be delusions and hallucinations which run a rapid course. The hallucinated objects are usually moving and multiple. Sometimes there are illusions in which the patient's bed becomes a boat or a train and his conversation indicates that he has a sensation of being in motion (vestibular irritation?). Some patients have transient manifestations of the Korsakow phenomena. Restlessness may become extreme and the patient may call out loudly, shout or scream, and become very disturbing to others. Restraints usually are necessary because patients react to hallucinatory experiences and delusional ideas. They try to join relatives whom they fancy are in an adjacent room, they may run away, jump out the window, et cetera. There sometimes is miming of familiar or occupational activities, and the miming may be of varying degrees of elaboration such as sewing, smoking or going through the complicated movements of dressing or undressing. Wolff and Curran[16] cite a bromide patient who had a police record and fancied that he was in a bootlegging drama. He thought that he was about to be "put on the spot" and enacted a scene rich in activities of fear and defense. Another patient built a bathing platform and jumped from the top of the table to the floor which he believed to be a lake.

One frequently must answer the question: "In a given patient, for what part of the psychotic picture are the bromides responsible?" Levin[5] states that if in an attempt to control the symptoms of a psychosis a patient is given bromide and there is no subsequent change in the psychotic picture, the case cannot be regarded as

one of bromide psychosis. On the other hand, if following the administration of bromide the psychotic picture changes, the possibility of a bromide delirium must be considered. Bromide deliria usually clear up in from two to six weeks following discontinuance of the offending drug. However, either the underlying psychosis may persist after termination of the delirium and cause the psychiatrist mistakenly to dismiss from his mind the possibility that a bromide delirium ever existed, or a bromide intoxication theoretically may give rise to a chronic psychosis so that a patient who is not psychotic before the delirium fails to return to his normal health many months after the bromides have been discontinued.

Harding and Harding[2] believe that there exists a rough correlation between the amount of bromide in the blood and the type of mental reaction resulting therefrom. Patients with simple bromide intoxication or depression usually show a serum bromide of 100-150 mg. per 100 c.c. while a serum bromide of 150-300 mg. produces bromide delirium or psychosis. Serum bromides above 300 mg. c.c. often cause the patient to become more or less stuporous. On the other hand, Katzenelbogen, et al,[4] studied a number of cases and concluded that there was no distinct correlation between toxic symptoms and the bromide level in the blood. Patients with serum bromide as high as 385 mg. did not show any clinical symptoms of bromide intoxication; in other cases, acne, loss of pharyngeal reflexes, vertigo, ataxia and weakness were observed in patients with serum bromide as low as 147 mg. These workers conclude, therefore, that in following patients under bromide treatment it is the clinical picture and not the laboratory findings which should be primarily reckoned with in regard to the menace of bromide intoxication. According to Wuth,[17] however, any serum bromide in excess of 150 mg. should be considered as being in the "toxic zone." Max Levin[6] agrees that a serum bromide over 150 mg. will tend to produce symptoms. Moreover, when the serum bromide is high, the psychosis may begin to clear up before the content gets back to 150 mg., or it may persist after it has fallen below the level. The underlying psychiatric makeup of the patient has a great deal to do with this. Walter[15] suggests that it might be due to altered permeability of the meninges.

Course

The duration of symptoms of bromidism following discontinuance of the drug is from two to six weeks. According to Levin[5] this duration is determined by the following factors:

1. Organic brain disease which undoubtedly retards recovery.
2. Pre-existing psychoses which probably have the same effect.
3. Even in the absence of 1 and 2, there probably are constitutional differences in the speed with which delirium clears up.
4. The duration after discontinuance may vary according to the duration of symptoms before discontinuance of the drug. For example, a delirium which had been present for several weeks before the bromide was discontinued probably will take longer to clear than one which has lasted for only a few days.
5. The administration of sodium chloride probably hastens the clearing up of the delirium.

Treatment

Naturally, the first thing to be mentioned under the treatment of bromide intoxication is prevention. Bromide dosage should be kept down to the minimum and should not be continued over a long period of time. A patient receiving bromides must receive chlorides. One must be especially careful in dealing with old people, arteriosclerotics, and patients suffering from cardiac decompensation or renal insufficiency.

When bromide intoxication does occur, the first thing to do is to discontinue administration of the drug in spite of intense restlessness and a disturbed mental condition. Bromides, as well as all other sedatives, must be withheld. Some writers believed that there was a "withdrawal delirium" probably analogous to the psychotic manifestations accompanying the withdrawal symptoms of chronic morphinism. However, in the case of bromides, the delirium depends upon a certain concentration of bromide in the blood, together with the resistance of the patient. As far as is known, following the abrupt withdrawal of bromides, there are no secondary reactions unless something intervenes to reduce the resistance of the patient. For this reason, the first procedure in the treatment of brominism should be to discontinue the drug. Next, the chloride content of the blood must be increased and this is best done by the intravenous administration of

normal salt solution and the giving of Na Cl by mouth. I usually give a capsule of 15 gr. (1.0 gm.) Na Cl four times daily. Patients who are very restless usually respond to hydrotherapy in the form of continuous baths or neutral body packs. When giving packs, care should be exercised that the pack is not warm enough to cause the patient to perspire excessively, for in that manner more chloride will be lost from the body. Elimination through the intestinal tract may be accomplished by a course of calomel followed by a saline cathartic. Sometimes spinal drainage helps to overcome restlessness and to eliminate bromide from the central nervous system.

With patients who are extremely disturbed and who are approaching a state of exhaustion and in whom the need for immediate rest is imperative, either paraldehyde by mouth or sodium amytal intravenously is usually adequate. I have used retention enemas of paraldehyde in olive oil, but with this form of administration there is some danger of producing gangrenous proctitis. Additional treatment of bromide intoxication or delirium is purely symptomatic and not complicated.

Toenhart[12] states that with bromides in the blood serum, hydrobromic acid is secreted by the stomach, neutralized, absorbed by the intestine, and later re-excreted into the stomach, thus producing a vicious circle. If in bromide intoxication the ratio of bromides to chloride is anywhere near the ratio of these ions to each other in the blood stream, then gastric aspiration should offer a rational and effective method of relief. Toenhart advocates gastric aspiration repeated several times daily over a period of several days. This removes as much of the bromide as possible, but chloride is necessarily removed also, so must be replaced either intravenously or orally. With Toenhart's method it is possible to remove as high as 1,240 mg. (20 gr.) of bromide in eight hours using continuous gastric aspiration with a negative pressure apparatus.

Many cases diagnosed as bromide delirium or psychosis were seen in hospitals not equipped to run serum bromide determinations, so we cannot consider these as proven cases. However, the history, clinical picture and subsequent course in every one of the unproven cases is so characteristic that we seem justified in assuming that they were cases of true bromide psychosis. Some of these were superimposed upon pre-existing psychoneurotic conditions. Only a few typical ones will be cited, and then we will go on to proven cases. For the sake of brevity irrelevant features of the histories, physical findings, and clinical courses will be omitted.

Case Histories

Case 1.—A white man, aged fifty-four, was taken to a hospital with fractures of the right femur and tibia suffered in an automobile accident. There was a history of preceding chronic alcoholism. The fractures were reduced under ether anesthesia and a spica cast applied. The immediate post-traumatic course was uneventful, but on the third day the patient developed signs of delirium tremens. He was given 20 gr. of sodium bromide five times a day and occasional hypodermics of morphine. He became semi-stuporous, progressively more noisy and disturbed and developed hallucinations of sight and hearing. He was disinclined to eat and his feeding was neglected. The more disturbed he became, the more bromide he was given. After ten days, his condition had become serious and I was asked to see him. The patient was semi-stuporous, noisy, incoherent, restless and in full restraint. The lids were heavy, eyes glassy, breath fetid, and tongue furred. Speech was slurring, and when the patient attempted to reach for anything (restraints had been removed during the examination) it could be seen that his arms were very ataxic. All tendon reflexes were abolished but there were no pathological reflexes. The temperature ranged between 100 and 102° F. and the pulse varied around 104. A tentative diagnosis of bromide poisoning was made. All sedatives were discontinued, a spinal drainage was done, and the patient was given saline solution intravenously and NaCl by mouth. The serology on the spinal fluid was normal. On the third day the patient was much more quiet, and from then on there was a gradual amelioration of all psychotic symptoms. On the tenth day after treatment was instituted the patient was discharged from the hospital.

Case 2.—An unmarried white woman, twenty-four years old, developed symptoms of a mild anxiety neurosis, following the unsatisfactory termination of a love affair. She was mildly depressed and disinterested, had occasional crying spells, was unable to sleep at night, and wished that she were dead. Her attending physician sent her to a hospital and prescribed 20 gr. of a bromide mixture three times a day and at bedtime. On the sixteenth day of treatment the patient became confused and hallucinated. She thought that the trees outside her window were waving at her and that voices were coming from the light socket on the wall. She was restless, resistive and could be heard occasionally to call out loudly for various members of her family who she imagined were in an adjoining room. I was asked to see her on the twenty-third day after she entered the hospital and found her in an active delirium. She was somnolent and restless, it was impossible to secure her attention, most of her answers were irrelevant and she was completely dis-

oriented for time and place. She spoke frequently of small aeroplanes she saw flying around her room. The neurological examination showed the pupils to be small but active to light. The patient was unable to accommodate. There was a fine bilateral nystagmus and the speech was slurring. All tendon reflexes in the arms and legs were brisk but no pathological reflexes were elicited. Coördination could not be tested. A diagnosis was made of bromide intoxication superimposed upon an anxiety neurosis and eliminative and supportive treatment was instituted. All sedatives were discontinued, NaCl was given parenterally and by mouth, and the patient was fed by nasal tube. I did not see her again but her physician reported that three weeks after treatment had begun all signs of delirium had disappeared and the clinical picture had returned to the original one of an anxiety neurosis. From then on, this patient's illness ran a course typical of this disease and she eventually made a complete adjustment..

Case 3.—A thirty-five-year-old white man was taken to a hospital in a distant town, suffering from chronic alcoholism. He had been drinking on an average of a quart of cheap whiskey every day for three months. For two weeks prior to his admission to the hospital he had been mildly confused and in the habit of taking long walks alone in the country. One day he was picked up in a neighboring town in a dazed condition, not knowing how he got there. He was taken to the hospital and placed on bromides and chloral by mouth. On the eleventh day his mental condition had become much worse and I was asked to see him. I found a powerfully built man lying in bed secured by restraints on all four extremities. He was yelling, cursing and shouting. Distractability was extreme and the patient was completely disoriented. Any examination was practically impossible but the patient's chart showed that his temperature was varying between 100° and 102° F. rectally and the pulse around 120-140. Very little food had been taken. The chart also showed that during the eleven days the patient had been in the hospital he had received 2,200 gr. (14.6 gm.) of bromide, 1,100 gr. (7.3 gm.) of chloral, 45 gr. (3.0 gm.) of phenobarbital and several hypodermics of hyocin. Immediate discontinuance of all sedatives was advised, and NaCl was given intravenously and by nasal tube. Restlessness was controlled by warm, moist body packs, and on two occasions it was necessary to administer ½ ounce (7.5 c.c.) of paraldehyde in an oil retention enema to control the restlessness. I did not see the patient again but the attending physician reported that he made gradual but steady improvement, and in three weeks was discharged from the hospital in good condition.

It must be admitted that in none of the above cases was the existence of bromide intoxication proven by laboratory methods. However, the fact that the patients were steadily growing worse under bromide medication, developed an acute delirious psychosis, and improved promptly and consistently upon withdrawal of the drug and replacement by chlorides, is significant. In the following three cases definite laboratory evidence of elevated serum bromide was obtained at the height of the psychoses. Blood bromide determinations were made by Miss M. Seltz, laboratory technician at Mounds Park Sanitarium in St. Paul. The LaMotte comparator was used. As a colorimetric method, this is fairly accurate.

Case 4.—A white man, sixty-nine years old, was admitted to a hospital on February 25, 1937, complaining of intense vertigo associated with attacks of nausea and vomiting. From the description of the symptoms, I believe that he was suffering from a labyrinthitis. The physical, neurological and psychiatric examinations were negative throughout. Because of a mild hypertension and some signs of renal insufficiency, the patient was placed on a salt-free, meatless diet, and was given 15 gr. (1.0 gm.) sodium bromide six times a day. To offset this amount of bromide, he should have taken 360 gr. (20 gm.) NaCl every twenty-four hours but he was on a salt-free diet. After a few days the patient's vertigo and vomiting ceased and he was in good spirits and progressing satisfactorily. By March 10 he was up and walking around but still receiving bromide and no salt. On March 12, he began to have thickness of speech and anorexia (nurse's notes). He developed fever and pain in the chest and x-ray films showed a bilateral basal bronchopneumonia. A medical consultant was called by the attending physician and his notes state that the patient was too confused to permit a satisfactory examination. Mental confusion and restlessness continued and the patient was given frequent hypodermics of dilaudid. The febrile condition lasted for about ten days and during that time the patient did not take anything by mouth, so received no bromides. After his fever subsided his mental condition persisted and I was asked to see him on March 27, 1937. He had not received any bromide for fifteen days, but he was confused, restless, disoriented and hallucinated. He expressed delusions of infidelity and many of his formulations had a marked persecutory trend. The speech was slurring and the eyes staring but the skin was clear. The patient's mental condition was such that commitment to a state hospital had been advised. In reviewing his chart, I found that the patient had received 1,350 gr. (90 gm.) of sodium bromide in fifteen days, but no NaCl. Fifteen days after the last dose of bromide, his serum bromide still was 160 mg. per 100 c.c. This is in the toxic zone. NaCl by mouth and parenterally was advised and paraldehyde was used to control the restlessness. On the fourth day the patient was eating well, but was still confused and disoriented. On April 8, eleven days after treatment was started, the patient was walking out of doors, and on April 11, two weeks after institution of NaCl and supportive treatment, the patient was discharged from the hospital perfectly clear and rational mentally.

In this case it might be argued that the patient was suffering from a toxic delirium secondary to his pneumonia. I am inclined to doubt this, first, because the pneumonia was not a very toxic one, and the delirium was present to some degree before the temperature rose. Furthermore, the delirium continued for some time after the pneumonia had subsided, it was accountable for by an excess of serum bromide and it subsided when treatment for bromide delirium was instituted.

Case 5.—A white man, aged forty-two, with a history of occasional alcoholic excesses, was greatly upset by the death of his wife on March 1, 1937. He began to drink excessively and on March 10 consulted his family physician, who made a diagnosis of chronic alcoholism and melancholia. The patient was advised to stop drinking, which he did, and was placed on 20 gr. NaBr four times a day. On March 24 his gait became ataxic and his speech slurring. By March 28, his arms also were ataxic and it was impossible for him to feed himself. He was mildly confused and, because of the mental state and the ataxia, syphilis of the central nervous system was suspected and the patient was sent to the hospital for study. I saw him on March 28 and found him to be well oriented, but very sluggish mentally. There was profound emotional depression with a strong tendency to cry at the slightest provocation. The speech was slurring, there was a fine bilateral nystagmus, and all tendon jerks were reduced. There was marked bilateral ataxia of the arms and legs. The blood Wassermann was negative and the cerebrospinal fluid gave normal serology and cytology. The blood serum bromide was 310 mg. per 100 c.c. Under NaCl treatment, moist body packs, massage, and withholding all sedatives, the patient improved gradually and was discharged from the hospital on April 20 completely recovered from his ataxia, slurring speech, and mental sluggishness, but still emotionally depressed to a modest degree.

This was a case of simple bromide intoxication and had not yet gone on to the stage of delirium or psychosis. The clinical picture was very similar to that of tabo-paresis.

Case 6.—M.P., a white woman, aged fifty-two, was first seen by me in consultation on March 3, 1937. She was suffering from a moderately severe anxiety neurosis with numerous gastro-intestinal preoccupations. The neurological and physical examinations gave normal findings. A plan of treatment was outlined and the patient made satisfactory progress, being discharged from the hospital by her physician on April 9, 1937. On April 23, I was asked to see her again because she had returned to another hospital in a state of acute delirium. She had gone home taking 20 gr. of bromide mixture four times a day. We learned from relatives that she had had a return of her gastro-intestinal symptoms and since going home had eaten very little. When I saw her the second time she was confused, totally disoriented, and noisy enough to disturb other patients in the hospital. She was extremely restless, her speech was slurring, the lids were heavy, and the eyes had a dull staring expression. The tongue was dry and furred and the breath was foul. The neurological examination, as far as could be carried out, was normal. Blood serum bromide was 275 mg. per 100 c.c. The usual treatment was instituted and at the time of this report, May 2, 1937, the patient is more clear mentally, quiet, but still restless.

Comment

It will be noted in the above cases that the patients were taking moderately heavy doses of bromide over relatively short periods of time. However, none of them was eating a sufficient amount of food and, consequently, not getting enough chloride. This probably accounts for the early appearance of toxic symptoms in these cases. The fact that toxic symptoms were present for only a short time before treatment was instituted accounts for their rapid disappearance after treatment was begun.

The question naturally arises — why, with thousands upon thousands of people receiving bromide medication, do we not encounter more cases of intoxication? That is a difficult question to answer but I believe that it can be explained, in part, on the basis of individual susceptibility. Some people have a lower "delirium threshold" than others. We all know individuals who become delirious with relatively slight rises in temperature regardless of the cause. On the fever up to 105° to 106° F. without showing any signs of delirium. Then there is the question of individual susceptibility. Some people get sick on as little as 15 gr. (1.0 gm.) of potassium iodide a day, and then there are others who can take 200-300 gr. daily without the slightest difficulty. The individual variations in susceptibility to alcohol are too well known to merit discussion here. Decreased powers of elimination due to arteriosclerosis and renal insufficiency also favor intoxication in some cases, and in others the presence of another toxic factor such as alcohol or toxemia due to infection tends to aggravate the clinical picture. I feel, therefore, that one or more of several factors are necessary to produce bromide intoxication. These are: the administration of moderately large doses of bromide, decreased chloride intake, low delirium threshold, heightened individual susceptibility, and impaired elimination or the presence of another toxic factor such as alcohol or infection.

Summary and Conclusions

1. Due to the increase in functional nervous diseases more bromides are being prescribed than formerly.

2. In susceptible individuals bromides may produce mental symptoms even where given in usual therapeutic doses.

3. The effects of bromide are largely confined to the central nervous system. Bromide tends to displace chloride in the blood stream.

4. With the administration of bromide an adequate chloride intake is necessary to prevent bromide intoxication.

5. The toxic effects of bromide may be described as simple bromide intoxication or depression, and bromide delirium or psychosis.

6. Blood serum bromide in excess of 150 mg. per 100 c.c. is in the "toxic zone."

7. The duration of symptoms of brominism following discontinuance of the drug is two to six weeks.

8. Treatment of bromide intoxication consists of discontinuing the drug and all other sedatives, the administration of NaCl orally and parenterally, hydrotherapy, and, in urgent cases, quick acting and rapidly eliminated sedatives. Spinal drainage sometimes helps, and gastric aspiration has been recommended to help eliminate the bromide.

9. Three probable cases and three proven cases are briefly reported.

ACUTE PULMONARY EDEMA OCCURRING DURING PREGNANCY OR LABOR*

F. J. SCHATZ, M.D.
Saint Cloud, Minnesota

ACUTE pulmonary edema as a terminal complication of pregnancy or labor is a most serious one and a rather frequent complication of eclampsia, occurring in almost one-third of the eclamptic cases. Its incidence in eclampsia without convulsions is even higher.

Acute pulmonary edema occurs late in the course of pre-eclamptic and many fatal cases of eclampsia, and during labor in cases with cardiac decompensation without audible valve lesions. It has been suggested that it may develop in the fatal cases of eclampsia as an end-result of the failure of the pulmonary circulation. On the other hand, the fact that not all cases of pulmonary edema end fatally seems to exclude this explanation.

Slemons[4] found acute pulmonary edema in six of seven cases of eclampsia without convulsions which came to autopsy.

King, et al,[3] report a series of thirty cases of ante- and intrapartum eclampsia with four cases of edema of the lungs with three recoveries. The fatal case was a colored woman, who had marked pulmonary edema on admission. The edema was relieved by appropriate treatment. She was delivered by a very easy low forceps operation seventeen hours after admission. Through a misunderstanding, ether was used as the anesthetic with a recurrence of the edema, broncho-pneumonia and death. The edema has been reported in all stages of pregnancy from the second month[1] through to term, during delivery[6] and in the puerperium. However, its greatest incidence is after the fifth month of pregnancy. It is more frequent in multiparas than in primiparas[5] and

*From the Obstetrical Department, St. Cloud Hospital. Read before the joint meeting of the Stearns-Benton and Upper Mississippi medical societies at Little Falls, Minnesota, October 21, 1937.

rarely seen in non-pregnant subjects. While it may complicate many types of cardiac lesions, in most cases it follows mitral disease, and many patients with mitral lesions have no disturbance during pregnancy or labor. In some reported cases, however, there has been no history of cardiac symptoms before pregnancy.

Pathogenesis

Bustos Moron[1] summarizes the old theories of pathogenetic mechanism of this conditions as follows: (1) a mechanical disturbance, pulmonary hypertension and acute weakness of the right ventricle; (2) a reflex disturbance originating in aortitis and peri-aortitis; and (3) a toxic element which is always present. These are all elements which collaborate in the production of the syndrome. On the other hand, today the mechanism of the attack is considered due to a severe left ventricular insufficiency. Bustos Moron believes, along with Waldorp, that within a few seconds after the occurrence of the left ventricular defect, a sudden pulmonary flux is produced, the whole parenchyma becomes congested from vertex to base, and the serous transudate causes edema of the lung. According to my observation, the edema comes on in a few minutes after the initial cough. There is a marked bronchorrhea, fine sub-crepitant and bubbling râles with some impaired resonance. This confirms the diagnosis made on the basis of the facies and the repeated cough, with an abundant or scanty yield. The pulse is lost, there is an increase in frequency and sudden hypertension, the dyspnea increases to orthopnea, consciousness may be lost, and death may follow unless proper therapeutic measures are instituted.

Symptoms

The onset is sudden, the cough persistent, and there is a sense of thoracic constriction soon followed by increasing dyspnea and precordial pain. There is marked cyanosis and spumous, salmon-colored expectoration containing blood. Fine râles may be heard at the lung bases and later throughout the lungs of the bubbling type.[2] The increased respiratory sounds obscure the heart tones, but a systolic murmur or a diastolic rumble may be heard at the apex. The pulse is rapid and thready or may be hard and tense, especially in the eclamptic type. The blood pressure is variable, the differential pressure tending to diminish. The temperature is normal or even subnormal. Albuminuria will be present at the end of the attack even in the absence of a pre-existing nephritis.

Types

Szer[5] distinguishes three clinical types of acute pulmonary edema in pregnancy. In the acute type, suffocation is intense and the patient may die within a few minutes with a pink froth on her lips. In the bronchoplegic type, expectoration is absent but the patient has severe dyspnea with thoracic pain. Signs of cardiac weakness appear rapidly. The patient does not cough and fluid accumulates in the bronchi and lungs. Cyanosis is marked, the blood pressure decreases and death may follow quickly in spite of treatment. The subacute forms are most frequently encountered. These are characterized by a nocturnal pseudo-asthma, described as a cardiac asthma by some authors, which awakens the patient. There is dyspnea with pink, foamy expectoration. Examination will reveal localized areas of edema. These attacks may be repeated frequently at night until the acute form appears.

Diagnosis

The typical forms are readily diagnosed. Diagnosis is based on the sudden onset of cough, the intensity of the edema, the characteristic edema and the auscultatory signs.

The condition may be confused with asthma, but in the latter there is a history of a previous attack and the dyspnea is of the expiratory type. Expectoration appears only at the end of the attack. The sputum is thick and contains eosinophiles. Pulmonary embolism and suffocating pneumothorax must be excluded in the diagnosis of the bronchoplegic type and this is affected by the pain in the side and the absence of expectoration.[5]

Pathology

In an autopsy reported by Teel, et al,[6] the gross and microscopic findings were interpreted as indicating that the patient suffered from a true acute toxemia of pregnancy. The pathologic lesions in the liver, kidney and brain were similar to those found in fatal cases of eclampsia, except that they were less marked. The findings in the heart and lungs were interpreted as indicative of "acute left ventricular failure, resulting in marked pulmonary congestion and edema

with slight emphysema." The heart weight (335 grams) and the subendocardial fibrosis of the myocardium and the mitral leaflets were insufficient to justify a diagnosis of chronic heart disease. No organism could be demonstrated in the myocardium or grown from a spleen culture.

Prognosis

The immediate prognosis is based primarily upon the amount of expectoration and the condition of the blood pressure but also depends largely on the promptness with which treatment is instituted. A large amount of expectoration is a favorable prognostic sign. Gallop rhythm, alternating pulse and a decrease in the differential blood pressure indicate insufficiency of the left ventricle and, consequently, offer a poor prognosis. In the presence of persistent râles at the bases, high diastolic pressure and arrhythmia, a guarded prognosis is indicated.

If the patient survives delivery and the early puerperium, the ultimate outlook as regards chronic cardiovascular and renal disease is good. Teel, et al, reported six cases, with two deaths. Three of the surviving patients were alive and well without cardiac, vascular or renal sequelæ, eight, six and two years after the attacks. King, et al, report four cases with one immediate maternal death.

Treatment

The basis of the treatment of acute pulmonary edema is heroic doses of morphine with atropine and heart stimulants, with venesection to reduce the venous hypertension and relieve the pulmonary circulation. Immediate relief follows the removal of 500 to 700 c.c. of blood. Peripheral venostasis has been recommended as an alternate to venesection.

Cardiac weakness indicates a cardiac tonic, as ouabain, which acts rapidly when given intravenously. Assuming that the attacks are similar in mechanism to classical cardiac asthma, Teel, et al, feel that digitalization is indicated. These same authors also believe that the prophylactic use of digitalis in all eclamptics and patients with severe non-convulsive toxemia in and above the fourth decade of life should be considered. The results obtained by digitalization in the severe decompensated hearts at times are not what one would expect even with larger doses than that usually given.

From the obstetrical viewpoint, Szer believes that, while there is no fixed rule, early interruption of the pregnancy is indicated in those cases in which signs of grave cardiac insufficiency are present at the onset of pregnancy. Cesarean section should be considered when serious attacks occur repeatedly in spite of medical treatment. From a limited experience, Teel, et al, concluded that significant clinical improvement was not to be expected until the uterus was emptied. The optimum time for interference appears to be between twelve and forty-eight hours after the attack. This delay gives sufficient time for digitalization before the interruption of the pregnancy is undertaken.

Delay, as suggested by Teel, et al, may be tried in patients with a favorable cardiac condition and a mild lung involvement. The edema, however, may become suddenly severe and terminate fatally. In the more severe cases, the treatment must be instituted promptly and the uterus emptied as soon as possible. The bleeding after delivery is profuse and appropriate treatment must be instituted to control same.

When acute edema of the lungs occurs towards the end of pregnancy, it is often followed by labor. If necessary, dilatation may be completed manually and delivery effected by means of forceps or version.

Case Reports

Case 1.—Mrs. J. T. L., gravida 1, aged twenty-seven, had had the diseases of childhood, smallpox, tonsillitis, influenza, tonsillectomy, dyspepsia with urticaria of one week duration in 1932, Schoenlein's disease with a kidney complication and mitral insufficiency following an upper respiratory infection in 1923. Her last menstrual period was December 25, 1926, and the date of expectancy was calculated for October 1, 1927. The family history was negative. Edema of the lower extremities appeared when she was six months pregnant. Because of financial difficulty, she continued with her professional work as a nurse, which necessitated being on her feet a great deal. She was advised to discontinue working but refused. October 1, 1937, she was admitted to the hospital with a generalized edema and a mild respiratory embarrassment, temperature 98.2, pulse 80, respirations 28, blood pressure 160/120. Urinalysis of a catheterized specimen showed sp. gr. 1.014, acid, albumin 2 mm. ring, acetone, diacetic acid, R. and W. B. C. Other physical findings were negative including examination of the heart.

She was given castor oil and a hot pack to stimulate elimination; spontaneous rupture of the membranes occurred four hours later. Her progress was slow and the patient was in labor forty hours. Morphine and

scopolamine with ether in oil per rectum and magnesium sulphate intramuscularly were used during the first stage of labor. The head remained high in the right transverse position; the cervix was about two-thirds dilated. Suddenly the patient developed a cough with râles in both lungs, temperature 98.3, pulse 114, respirations 48. Appropriate medication was given and the patient prepared for delivery. Labor was terminated by manual dilatation of the vagina and cervix, with a difficult high forceps operation. The baby was in fair condition. A severe postpartum hemorrhage occurred after the expulsion of the placenta. The uterus was packed and 1 c.c. each of pituitrin and ergot were given by hypo. The estimated blood lost was 750 c.c., pulse 118, respirations 50. The patient's condition was poor. There was considerable bleeding the first postpartum day partially controlled with ergot. The labored breathing continued for twenty-four hours. The lungs were free of râles by the fifth postpartum day. The patient was able to leave the hospital on the thirteenth postpartum day. A subsequent pregnancy fifteen months later was normal throughout.

Case 2.—Mrs. J. L., gravida 4, aged forty, had her last menstruation August 4, 1928. She had had rheumatism in 1923, spontaneous full-term delivery in 1927, and rheumatism in 1928 when two months pregnant. Urinalysis at this time showed albumin, hyaline and granular casts, R. and W. B. C. No blood pressure readings were recorded at this time by the attending physician. There was no prenatal care.

The patient was first examined by me April 11, 1929. She was in labor and she was coughing, breathing laboriously, cyanosed, and sitting up and stooped forward. Crepitant râles were heard in both lungs, and a systolic heart murmur heard at the apex and transmitted to the axilla. Morphine 0.01 (gr. 1/6) with atropine 0.0004 (gr. 1/150) was given with relief in one-half hour. The patient was prepared for delivery, anesthetized, catheterized, the cervix dilated manually, and forceps applied to the head in L. O. A. position. Delivery was easily accomplished. The baby was thin but in good condition. The lungs were clear after forty-eight hours. The patient made an uneventful recovery following her delivery. The heart and kidney condition remained unchanged. The patient was up and about the tenth postpartum day.

On May 9, 1929, while sitting at the table after supper, she was suddenly seized with a severe attack of coughing with labored breathing, cyanosis, expectoration of a serous, frothy, blood-tinged fluid (about 500 c.c.). Bubbling râles were heard in both lungs, the heart was rapid and a systolic murmur was heard over the aortic area which was transmitted into the neck, and a systolic murmur over the heart apex transmitted into the axilla. Morphine 0.01 (gr. 1/6), atropine 0.0004 (gr. 1/150), were given by hypodermic and the atropine had to be repeated in a half hour before the patient got any relief from the edema of the lungs. The heart was digitalized, and the morphine and atropine had to be given daily for a week before the lungs remained clear. The swelling gradually became generalized with accumulation of fluid in the peritoneal cavity. The urinary output diminished until there was complete suppression. The patient expired February 19, 1930, from cardio-renal dropsy. Necropsy was not obtainable.

Case 3.—Mrs. J. W., gravida 2, aged thirty-three.

The patient was seen in consultation and referred by Dr. A. Mahowald. At the age of thirteen, she had had pain during and after urination for three or four days. She had had many of these attacks up to the time of her marriage seven years ago. She had had measles at the age of twenty-one, and edema of the lower extremities during the last month of her first pregnancy. She went to term and was delivered by an easy forceps operation. She had her last menstrual period March 25, 1930. The date of expectancy was January 2, 1931.

About one month prior to the development of the complication, she was examined by her physician for swelling of the lower extremities. On the afternoon of January 1, 1931, she developed a mild cough with free expectoration of fluid which gradually increased in amount. At about eleven P. M., the patient was awakened, smothering, with fluid escaping from her nose and mouth, coughing severely and breathing with difficulty. The family physician was called and he immediately took her to the hospital. She did not remember anything other than riding fast in a car. She was admitted to the hospital at 12:55 A. M.. Her physician ordered a hot pack and an enema, and magnesium sulphate was given by mouth, but was not retained. At 3:10 A. M., she was given 0.03 (gr. ½) codeine with some relief for one hour. At 4:30 A. M., he took her to the delivery room and packed the cervix with sterile gauze to induce labor, but was unsuccessful. The patient was seen by me at 7:30 A. M. She was sitting up in bed supported by a back rest. Serous blood-tinged fluid was escaping from the mouth and nose; she was coughing and vomiting simultaneously and struggling for air. The patient was cyanotic, cold and clammy, and there were bubbling râles in both lungs. The heart tones were regular, rapid, and difficult to detect; the pulse 120, respirations 42. Urinalysis: Albumin 2 mm. ring; hyaline and granular casts, R. and W. B. C. Morphine 0.01 (gr. 1/6), atropine 0.0004 (gr. 1/150) was given by hypo, and the atropine was repeated in ten minutes. The lung condition cleared sufficiently to allow the patient to be moved to the delivery room and prepared for delivery. The patient was placed in a semi-Fowler position; oxygen was given for the cyanosis; she was anesthetized with N_2O. After catheterization, the cervix was dilated manually, forceps were applied to head in R. O. P. position and the head was so delivered. The baby was in good condition. The patient was given ergot 1 c.c. per hypo to stimulate uterine contraction. Oxygen was given for the cyanosis. The placenta was expressed. Some 500 c.c. of blood was lost after the placenta was expelled. The tendency to bleed was marked and ergot had to be repeated in an hour. Two hours after delivery atropine was given for recurrence of the edema. The patient coughed a great

deal the day of delivery, with free expectoration of bloody mucus. The blood pressure after delivery was 140/100, the temperature 101, pulse 100, and respirations 40. The progress was uneventful after the second day and the patient was discharged on the eleventh postpartum day. The blood pressure on the day of discharge was 110/70.

Her third pregnancy was without complication. She had her last period on December 25, 1931, and delivered spontaneously on August 28, 1932, one month earlier than the date of expectancy. A trace of albumin with moderate swelling occurred at the end of the seventh month with a blood pressure of 150/110. The blood pressure returned to normal and the urine was free of albumin following rest, diet, and the limitation of the fluid intake. Her weight the day of her first visit, February 28, 1932, was 182 pounds and the blood pressure 110/70. The day of her delivery her weight was 189.5 pounds and B. P. 130/88.

Her fourth pregnancy in 1936 was normal throughout.

Case 4.—Mrs. H. L., gravida 6, aged thirty-six, had had five full-term pregnancies, of which four were normal. During her fifth pregnancy, on the day of delivery, she developed a severe headache, vomiting, and numbness in the lower extremities. Her blood pressure was 160/100. The urinalysis of a catheterized specimen showed albumin 2 mm. ring; sp. gr. 1.020, hyaline and granular casts, R. and W. B. C.

She had had her last period September 16, 1930. The date of expectancy was June 23, 1931. The heart, kidney, and blood pressure were normal throughout the gestation. During the week prior to entering the hospital, she had respiratory difficulty which would occur from one to two hours after lying down at night. She was examined about midnight, June 7, 1931, in her home. The patient was delirious and did not recognize her family. She was sitting up and struggling for air. There were many râles in both lungs; no heart murmurs could be heard. Her temperature was 98, pulse 128, and respirations 30. She was taken to the hospital and admitted at 12:10 A. M. A non-catheterized specimen of urine showed a trace of albumin. Blood examination: R. B. C. 4,250,000; W. B. C. 9,400; Hbg. 76%. Codeine sulph. 0.03 (gr. ½) was given for the relief of the edema of lungs and restlessness. The patient was relieved by the medication and was in fair condition in the morning. At ten o'clock A. M., the membranes were ruptured artificially. Castor oil and quinine were given. Contractions started three hours later, and she was in labor one hour and ten minutes before the baby was born. Fifteen minutes prior to delivery she suddenly developed cyanosis, a severe cough, labored breathing, and râles in both lungs. Her pulse was 160, and respirations 32. The patient was placed in a semi-Fowler position. Atropine 0.0006 (gr. 1/100) with whiskey 15.0 (oz. ½), pituitrin 0.3 (Mv.) were given to hasten delivery. The baby was delivered spontaneously in good condition. The placenta was expelled by the Credé method. The patient's condition was fair when she was taken to her room. She was placed in Fowler's position. Digitalis was given for the heart, oxygen for the labored breathing and cyanosis, morphine sulphate 0.01 (gr. 1/6) for restlessness and cough and ergot 1 c.c. to check the severe bleeding. After the fifth day the lungs were clear. The patient left the hospital on the eleventh postpartum day. The pulse was 96 and respirations 28. The patient's progress was slow and stormy. The heart was digitalized but never responded well to treatment. She died suddenly August 17, 1933, when she left her bed for elimination purposes.

Case 5.—Mrs. L. R. B., gravida 1, aged twenty-four, had had her last menstruation May 31, 1936. The estimated date of delivery was March 6, 1937; the date of delivery February 27, 1937. She was in labor sixteen hours.

This patient had had scarlet fever, measles, pertussis, diphtheria, chorea and rheumatism. She had had two attacks of rheumatism at the age of nine and sixteen years, her second attack lasting sixteen weeks. An appendectomy had been performed at the age of nineteen.

Physical examination on October 14, 1936, showed a well-nourished female sixty-seven inches tall, weighing 199.5 pounds. Her blood pressure was 170/70. All other physical findings were normal except that the heart was enlarged and a systolic murmur could be heard over all of the valve areas. She was about five months pregnant and her pelvis was large. The kidneys remained normal throughout the gestation and she gained 17.5 pounds from the time she presented herself for observation to the time of delivery February 27, 1937. The blood pressure dropped to 150/70 and gradually rose to 190/60 the day of delivery. The first pains came on about 3 A. M. and she entered the hospital at 7:15 A. M. Castor oil was given to stimulate contractions. On rectal examination, the head was mid-pelvic, the cervix thinned out and dilated about 2 cm. The fetal heart tones were heard to the right and below the umbilicus, 150 per minute.

The patient's heart condition was satisfactory and she was given her first dose of morphine and scopolamine at 2:05 P. M. At 3:15 P. M. she developed a slight cough which came at frequent intervals and fine subcrepitant râles were heard in both lungs; pulse 118, respirations 24. She was given atropine sulphate 0.0006 (gr. 1/100) with improvement. At 7 P. M., she had a recurrence of the lung symptoms and digitalin 0.0013 (gr. 1/50), strychnine 0.0016 (gr. 1/40) atropine 0.001 (gr. 1/75), were given by hypo. The atropine was repeated in twenty minutes. By this time the patient was cyanotic, the skin clammy, breathing labored, pulse 140 and there was free expectoration of blood-stained serum. She was taken to the delivery room and oxygen was given while being prepared for delivery. Under nitrous oxide anesthesia the perineum was dilated. The head in R. O. A. position was delivered by an easy forceps operation, the shoulders and body were delivered by the Christeller maneuver, the cord was clamped and cut, and the placenta expressed. One c.c. each of ergot and pituitrin were given per hypo

to control the uterus. Some 400 c.c. of blood were lost. The oxygen was started as soon as the child was delivered and kept up for fourteen hours before the cyanosis and lung edema began to subside. The heart stimulation had to be repeated at regular intervals, with morphine for restlessness and ergot to control the uterus. The labored breathing, edema and cyanosis gradually cleared and after forty-eight hours the patient was symptom-free, with the pulse returning to normal. The heart stimulation was continued and the patient was discharged the tenth postpartum day. The digitalis was kept up for two months and her final check April 15, 1937, showed the B. P. 150/60 with the heart condition improved so that the patient was able to resume her household duties.

Case 6.—Mrs. J. M. A., gravida 3, aged thirty-three, had had edema with her two previous pregnancies. Her complaint at this time was difficulty in breathing, especially when she was lying down. This condition, which she attributed to the varnishing of her home, had been of two weeks duration. When moving about she had less difficulty in breathing.

The patient was seen in the home by Dr. C. B. Lewis and taken to the hospital. The edema and cyanosis were generalized and there was morbid dyspnea, with many moist bubbling râles and expectoration of frothy, blood-stained, serous fluid. Her B. P. was 160/90, pulse 100, and respirations 30. Labor was induced and the baby was delivered with forceps. The patient's condition was poor. Cardiac stimulation and oxygen were given but she expired one and one-half hours after delivery. Bedside notes show that severe postpartum bleeding continued up to the time of death.

This case is reported with the permission of Drs. C. B. Lewis and W. L. Freeman of St. Cloud, Minnesota.

Conclusions

1. The strain of labor added to a weakened heart musculature with or without the presence of a valvular lesion is a definite factor in causing acute pulmonary edema.
2. With appropriate treatment before, during and after delivery, maternal mortality from pulmonary edema should be reduced to a minimum.
3. Severe bleeding occurred in five of the six cases and was responsible for one maternal death.
4. With proper antenatal care in subsequent pregnancies, a recurrence of the pulmonary edema may be prevented.

HYPERPYREXIA IN THE NEWBORN

Report of Infant With 107° F. by Rectum at Age of Fifty-three Hours

LARRY F. RICHDORF, M.D., Ph.D., and W. H. FORD, M.D.
Minneapolis, Minnesota

HYPERPYREXIA of 107° (rectal) in a newborn is unusual enough to warrant detailed analysis. In the case to be reported, this temperature was observed at the age of fifty-three hours. In the newborn a temperature as high as 104° (rectal) on the third day, or thereabout, is not necessarily associated with an unfavorable prognosis. In fact, in many a newborn moderate fever is transitory and recovery occurs without special treatment. The causative factors of transitory fever have been the subject of a great deal of controversy. Infection, inanition, dehydration, and birth trauma have been considered.

Salmi summarized the literature in 1935 and reported his observations in a series of infants delivered normally, by cesarean section, and by forceps. Transient fever of 100° to 104° with onset from the second to fifth day occurred in 20 per cent of the 225 infants of normal delivery. Long labors (over twenty-five hours) were three times as frequent in the infants manifesting fever as in the fever-free group. The birth weight was above 3,500 grams in 60 per cent of the cases showing fever, whereas only 30 per cent were above this weight in the fever-free group. The incidence of transitory fever in the newborn was increased when the membranes had been ruptured early (ten hours before delivery), when meconium was present in the amniotic fluid, or when vaginal examinations had been done.

Twenty-five per cent of infants delivered by cesarean section and 50 per cent of those de-

livered by forceps showed this phenomenon of fever. Salmi calls our attention to the fact that labor had been in progress a long time in many of the cases delivered by these two methods. Thus, long, hard, complicated labors *predispose* to temperatures ranging from 100° to 104° in the newborn.

Case Report

Baby boy F., weighing eight pounds, four ounces, was born March 26, 1936, at 5:15 p. m., the first baby (first pregnancy) of a mother nineteen years of age. Both mother and father were in good health. Labor was of fifteen hours' duration and normal except for an episiotomy. Nembutal (4½ grains) and scopolamine (1/200 grain) analgesia was used during labor and nitrous-oxide gas anesthesia during delivery. The amniotic sac ruptured one hour before the birth of the child. The amniotic fluid was definitely stained with meconium.

Mucus was removed from the nose and throat by suction with a soft rubber bulb before the infant made perceptible respiratory movements, and later, in the nursery, mucus was removed again in the same manner. During the first twenty-four hours after birth the weight loss was 4½ ounces and the temperature went from normal at birth to 102.2° rectal. During the second twenty-four hours the baby received 12 ounces of complement and water by mouth and 3 ounces of 5 per cent glucose in normal saline by rectum. During this twenty-four hours the rectal temperature ranged from 100.2° to 102.2° and the weight loss was 9½ ounces. This occurred without diarrhea or vomiting being present. At the age of 53 hours the baby's rectal temperature went up to 107°.

Examination at this time showed a somewhat spastic child, very hot to touch, with respirations 90 per minute. The thighs were flexed on the abdomen. The abdomen was slightly distended but no abnormal findings were noted on palpation. There was a slight areola of redness around the umbilical cord. The fontanelle was boggy but was not bulging, and it did not move with respiration. The mucous membranes of the nose, tongue and mouth were dry. The lungs were negative to percussion and auscultation. The heart was very rapid, estimated 200 beats per minute. Dehydration was obvious, and serious respiratory disease or cord infection was suspected.

Treatment: Whole blood (10 c.c.) and normal saline (100 c.c.) were given subcutaneously. One or both of these fluids were given in like manner every three or four hours. One ounce of 5 per cent glucose in water was given by gavage every three hours. During the first twenty-four hours of this treatment, the baby received 40 c.c. of whole blood from the mother and the father, and 550 c.c. of normal saline subcutaneously and 240 c.c. of 5 per cent glucose by gavage. The whole blood and normal saline were absorbed very rapidly. The respirations and heart rate came down to normal and the temperature dropped to 101.4° rectal within twenty-four hours after the beginning of this treatment. The weight curve was interesting. In spite of the fact that 15 ounces of fluid had been forced by mouth and rectum, the baby lost 14 ounces in weight in the fifty-three hours from birth until the time the temperature went up to 107°. The baby was not disturbed during the succeeding twenty-four hours, but forty-eight hours after subcutaneous fluid was started the baby had gained 17 ounces.

Breast milk was started twenty-four hours after the beginning of the subcutaneous fluids. The milk was expressed from the mother and given by bottle every four hours. The baby nursed well when it was put to breast forty-eight hours later. Both baby and mother were discharged from the hospital on the tenth day in good condition, the baby weighing 8 pounds 7½ ounces, or 3½ ounces over birth weight.

The areola about the cord disappeared but the cord remained attached for several days after leaving the hospital. An umbilical secretion was obvious for four months, during which time a slight hernia developed. This healed by strapping with adhesive tape. Examination at six months showed a perfectly normal child.

Summary

1. A large first-born baby developed a temperature of 107° rectal at the age of fifty-three hours.

2. There was marked dehydration, possibly respiratory or cord infection.

3. Rapid and complete recovery followed treatment with whole blood and normal saline subcutaneously, and water and glucose by gavage.

ABDOMINAL PREGNANCY AT EIGHT MONTHS*

PHILIP N. BRAY, M.D., M.S.
Duluth, Minnesota

THE literature on abdominal pregnancy was carefully reviewed by Cornell and Lash† (1933). In their series of 236 cases taken from the literature, their private cases, and the records of the Cook County Hospital, they reported that only 35 per cent were diagnosed correctly before operation. It is felt, therefore, that the presentation of another of these unusual cases is warranted, inasmuch as considerable diagnostic help may be obtained by use of the cystogram and the other usual x-ray studies.

Fig. 1. Cystogram, taken after 50 c.c. of 12 per cent sodium iodide were injected in the bladder. The bladder is distorted, its mid and left portions are flattened out.

Fig. 2. Anterior posterior radiograph, showing the fetus in the left lateral portion of the abdomen.

Fig. 3. Lateral radiograph of the abdomen, showing the breech presenting.

In the cases reported by Cornell and Lash, the condition was found most frequently in the first and second pregnancies. They found that in the eighty-six cases in which the baby was born after six months, the infant mortality was 22 per cent, whereas in the sixty cases in which the baby was born alive in the eighth and ninth months, the infant mortality was about 35 per cent. They found a maternal mortality of 14.3 per cent (thirty-four cases) in the total of 236 cases. Cornell and Lash concluded that removal of the placenta in toto is best when the placental blood supply can be ligated and when the site of the placenta is not attached to a vital organ. Also, they advised, when necessary, to combine marsupialization with drainage.

H. O., a white female, aged twenty-eight years, was admitted to the Minneapolis General Hospital September 8, 1933. The patient had had no prenatal care. She was a gravida ii, para i. Last normal menstruation was December 16, 1932, of four days duration. January 16, 1933, she flowed one day. February 22, 1933, she passed two small blood clots, then had no bleeding at all until four days before admission to the hospital.

The patient felt life June 1, 1933, and, she thought, until the day of hospital admission. She had never had any severe rupture-like pain, nor shoulder discomfort. Starting four days before admission at about 9:00 A. M., she had had moderate abdominal cramps coming about every two hours, bleeding a little less than that of a normal period, and frequency without pain or burning, to the extent of voiding about every forty-five minutes. Her bowels had moved that day, the stool being a little constipated, but not more so than usual.

Examination showed blood pressure 116/68, temperature 98.8°, pulse 78 and respiration 20. There was secretion from the nipples. A symmetrical pelvic mass was present on the right side extending within 3 cm. of the navel. The abdomen was soft, showed no peritoneal irritation, no fluid, no shifting dullness. On the left side of the abdomen there was a mass extending up to the costal arch. The upper pole felt

*From the Department of Obstetrics, Minneapolis General Hospital, University of Minnesota School of Medicine.

†Cornell, Edward L., and Lash, A. F.: Surg., Gynec. and Obst., 57:98, 1933.

like a fetal head, and could be palpated distinctly. The lower pole lay just above the pubic bone and could not be palpated distinctly. No fetal movements were felt nor heart beats heard. Pelvic examination showed a little sanguinous discharge from the vulva, floor was competent, and there was no evidence of

Dr. J. H. Simons and the writer. A lower midline suprapubic incision was made. Examination of the abdominal cavity showed the omentum to be attached to the mass in the right lower abdomen. The mass was the encapsulated placenta. The omental blood supply to the placenta was ligated in dissecting out

Fig. 4 *(left)*. Photograph of baby and placenta, showing the baby's length and maceration.
Fig. 5 *(right)*. Radiograph of baby, showing no evidence of syphilis in the long bones.

infection. Vaginal walls and cervix were only slightly blue, and the cervix was a little soft. There was a little bleeding from the cervix, about like that of a normal period. A symmetrical uterine-like mass, about the size of a three months pregnancy, occupied the right pelvic fossa. The breech, which lay to the left of the inlet, displaced this uterine-like mass to the right. Nothing abnormal was palpable in the cul-de-sac or either adnexa, but the left adnexa was a little tender.

A cystogram was taken after injection of 50 c.c. of 12 per cent sodium iodide in the bladder. The picture showed the bladder to be distorted, its mid and left portions being flattened out, apparently by the breech.

Anterior posterior and lateral radiographs were made, which demonstrated a single fetus lying anterior posterior and slightly transverse in the left lateral portion of the abdomen with the head to the left of the midline anteriorly opposite the first, second, and third lumbar vertebræ, and with the back posterior. There was a marked over-riding of the cranial bones, apparent collapse of the calvarium, and accentuation of the curves, indicating that the fetus was dead. The position of the fetus was one of extreme abnormality. Its density coincided with the continuation of the curves of the uterine mass, and its appearance definitely indicated that it was outside of the uterus.

The laboratory analysis showed hemoglobin 73 per cent; white blood count 10,500; polymorphonuclears 73 per cent; lymphocytes 25 per cent; and monocytes 2 per cent. Urine was entirely normal.

A preoperative diagnosis was made of:

1. Probable left extrauterine pregnancy with myomatous uterus or

2. Incarcerated dead fetus in a myomatous uterus.

Operative Record.—The patient was operated on by the placenta from its capsule. Further examination showed the uterus to be the size of a three months pregnancy lying in the true pelvis. The placenta was a trilobed mass adherent to the posterior abdominal wall, intestinal coils, and omentum. The placenta rested just above the uterus, but distinctly separate from it, and a little to the right of the midline. The lower portion extended over the brim of the pelvis posteriorly. Examination of the adnexa showed both ovaries to be normal. Both tubes appeared slightly thickened, but otherwise they also were normal. The appendix was not observed. Examination showed a dead female fetus in the left abdomen. The fetus had probably been dead only a short time, as there was very little maceration. The baby lay anterior posterior with head anterior, back posterior, and breech presenting. The amniotic sac had not ruptured. There were many adhesions between the amniotic membranes and viscera. The sac was firmly attached to the baby's head. Almost the entire area of the amniotic sac was adherent to intestines and abdominal wall, but these adhesions were easily released. The omentum, containing large blood vessels, was attached to the anterior surface of the placenta, to the ascending colon, descending colon, and small intestine. The cord extended from the opening on the left side of the placental sac over intestinal coils to the fetus. The placenta obtained most of its blood supply through the large omental vessels, and lay in a capsule of two portions, a rather thin amnion and an outer thick membrane.

The fetus and membranes surrounding it were liberated and the baby extracted with the cord. There was no line of cleavage to the outer thick placental sac, so this was opened and the placenta peeled out. There was considerable bleeding which was easily controlled by temporary packing. This thick sac remaining after the placenta was removed was cut down to its mesenteric attachments, leaving enough to approximate the edges together with a running suture. A Penrose drain

was inserted to take care of any oozing that might occur. After ascertaining that there was no free bleeding, the abdomen was closed.

During the operation the patient's blood pressure went down to 70/30. 1,000 c.c. of 10 per cent glucose solution and 600 c.c. of citrated blood were given in the right cubital vein. The pressure went up to 110/70, and the patient was returned to the ward in good condition.

The fetus measured 41 cm. crown heel, 28 cm. crown rump, and weighed 1,355 grams. The cord was 35 cm. long. The placenta weighed 735 grams, was the size of a grapefruit, and was composed of three equally large lobes.

Microscopic section of the placenta showed chorionic villi and trophoblasts with blood clots. Rather large areas were hyalinized and necrotic. The surface at one point was infiltrated with lymphocytes and eosinophiles. The microscopic diagnosis was placental tissue with infarcts.

The maternal blood came back Wassermann-positive, Kahn 4 plus. This was repeated with similar findings. The patient gave no history of syphilis, and had had no treatment. The baby had been dead long enough so that no blood was obtainable for the Wassermann test. Radiograph of the baby's long bones showed no evidence of syphilis.

The patient made an uneventful recovery, running a low grade postoperative temperature for five days, the highest reading being 100.4° on the day following operation. The Penrose drain was removed on the third day, and the patient was discharged on the fifteenth day.

ACUTE LYMPHATIC LEUKEMIA WITH REMISSION

H. G. BOSLAND, M.D.

Verndale, Minnesota

J. P., a white female, aged three, was first seen December 25, 1936, for what seemed to be an attack of upper respiratory infection with influenzal manifestations. She was obviously quite ill with high fever, rapid pulse and chills. Onset had occurred two days previously with the usual symptoms of a "head and chest" cold. The other members of the family were just recovering from the "flu."

Physical findings were acute tonsillitis and pharyngitis, a moderate bilateral cervical adenitis entirely commensurate with the throat pathology, a few rather coarse râles in either lung, temperature 103 by axilla, and a general appearance of pallor combined with what seemed to be a state of excellent nutrition but which also gave the appearance of being abnormal as a kind of generalized tissue swelling of a resilient type. The mother stated that all of her children and particularly this one had been large, heavy, and well-nourished as infants. The urine was normal.

The father, mother, one sister and two brothers are all living and well. There had been no deaths in the family. The mother had gone to full term with all of her pregnancies and had had normal deliveries. There had been no miscarriages nor stillborn infants.

Treatment was symptomatic for fever and restlessness, ice packs to cervical glands, mustard plasters to chest, swabbing of throat, and hot drinks. The following day the temperature was down to normal, the patient had rested well and appeared much improved clinically. No thought of leukemia at this time entered my mind, my diagnosis being acute tonsillitis and an upper respiratory infection.

The patient was not seen again until January 30, thirty-five days later, at which time the father called me because the child's "cold" had become worse again. The interval history revealed that she had not seemed to recover her usual strength and vigor and was often irritable and peevish. She had continued to have a watery rhinorrhea and an occasional slight fever but otherwise seemed well in that her appetite was fairly good and she played. Two days previous, she had become definitely worse. After a short examination, it was decided to take her to the hospital. Her temperature was 104.2 (r). An acute pharyngo-tonsillitis was present with a red angry looking patch on the right anterior pillar covered by a whitish exudate. The cervical nodes had increased in size, especially in the sub-mandibular region on the left, where the mass was very firm, somewhat tender, fixed, and seemed to represent a coalescence of several nodes. The ears were normal. The chest was normal on physical examination and x-ray. The urine was normal. Examination of the blood revealed a white count of 1,300, red count 2,450,000, Hgb. 30 per cent. In the differential, no pmns. could be identified with certainty. The predominating white cells were young lymphocytes. A blood smear was submitted to the pathology department of the University of Minnesota, the report returning with a diagnosis of acute lymphatic leukemia.

Symptomatic therapy was instituted: liquid diet, ice collar, sedatives. Liver extract was given parenterally in the hope that it might combat the neutropenia and anemia. Iron was given by mouth. Liver extract injections were made January 30, 31, February 4, 7, and 8. The temperature descended to normal in two days and remained within normal limits for five days. During this time, she consumed small amounts of liquids and a few soft foods, played with toys, noted her surroundings and in general seemed contented. Her face, however, was pasty, pallid, and puffy, the eyelids swollen. On February 5, the white count was 3,350, the red count and Hgb. unchanged. February 6, her temperature suddenly shot up to 104.4 (r) and the patient appeared extremely toxic. The swelling of the face and bloated appearance of the body increased. The sub-mandibular mass increased to the size of a lemon, was very tender, firm, and fixed. A mass in the left temporo-parietal region of the scalp which seemed fixed to the underlying periosteum and bone became more pronounced. A point of interest in this connection is that not only was this enlargement present at the very onset of illness in December but it had resulted from

a blow sustained in falling about three weeks before and had not subsided in the interval. In retrospect, after the diagnosis of acute leukemia by blood study was unmistakable, this incident had a significance which at the beginning I failed to appreciate.

The patient continued to lose ground rapidly. She was listless, apathetic, and evinced no interest in her surroundings. She did not play and took only sips of fluid when urged. Her temperature remained high and the pulse ran at 140 to 150, fair in quality at times but most often poor. February 8, because of an obstructive edema of the throat, she could swallow nothing. The floor of the mouth was swollen to such an extent that the mucous membrane, pale, watery, and distended, protruded over the lower incisors between them and the tongue. There was no bleeding from mucous membranes nor had there been at any time previously during her illness. February 9, a transfusion of 200 c.c. of citrated blood was given into a right antecubital vein. About eighteen hours after the transfusion, she was able to swallow liquids again. The temperature slowly fell to 101 by February 11, and the patient improved somewhat clinically. She was more contented, less distressed and irritable. The prognosis was of course as hopeless as ever and the child was discharged from the hospital when the father decided that if she must die she might just as well die at home.

February 13, two days after discharge from the hospital, her axillary temperature was 105 and the white count 6,000. Swelling of left cervical nodes rapidly increased. Inguinal and axillary nodes were palpable but small. At no time did these nodes become larger. Blood smears were submitted on this day and the report showed no more immature leukocytes but the polymorphonuclears showed severe toxic changes. The differential count was: polymorphonuclears 68 per cent, lymphocytes 30 per cent, monocytes 2 per cent. By February 19, the mass under the left jaw was fluctuating. It was incised and thick pus was freely evacuated. By February 22, her general appearance and condition were good. The patient was rapidly recovering strength, appetite, and normal activity. On February 25, the white count was 6,000, the blood smear report showed great improvement: no immature leukocytes and polymorphonuclears no longer appeared toxic. In the differential the polymorphonuclears were 58 per cent, lymphocytes 36 per cent, monocytes 6 per cent. Thus, during the following month, the patient was to all appearances and from all evidence a normal, healthy child.

On March 30, the father informed me that the patient had been worse again for the past week because of a "cold." On examination the child presented an appearance of marked toxemia and prostration. The temperature was high, the pulse weak and rapid, and the skin was literally covered by firm gray-blue nodules varying in size from that of a match head to that of a walnut, the largest infiltrated area being in the left temporo-parietal region. This mass, although less discolored than the remainder, had begun to assume a cyanotic hue. On close questioning the parents recalled that during the first week in March several of these nodules had been noted below the left clavicle, but inasmuch as they were small and painless and no more of them developed I was not advised of the circumstance. Furthermore, the child seemed well and happy. Shortly after her "cold" began, however, many more nodules rapidly appeared. The white count was 160,000; Hgb. 60 per cent. Examination of the chest revealed a large area of dullness suggesting pneumonic consolidation in the anterior portion of the left lower lobe. Because of abdominal distention, enlargement of the liver and spleen could not be definitely determined. There was no ulceration in the throat nor was there any evidence of bleeding from mucous membranes. A blood smear was submitted to the Department of Pathology, University of Minnesota, and again showed a typical acute lymphatic leukemia, nearly all of the white cells being immature lymphocytes. The child appeared moribund and the parents were so advised. General symptomatic measures of therapy were instituted and for the lack of anything better to do an injection of liver extract was given into the buttocks.

Due to the severity of the weather conditions and the comparative inaccessibility of the farmhouse, the child was not seen again until five days later, at which time examination revealed that the cutaneous nodules had all, to a marked extent, faded in color and diminished in size. The large temporo-parietal mass had decreased to one-third of its previous size. The other scalp nodules were scarcely palpable, whereas five days before they had been very obvious to sight and touch. The area of dulness in the chest had diminished. Clinically, she had definitely improved. Her eyes were brighter, she took an interest in her surroundings, and talked a little for the first time in a week. The temperature and pulse, however, remained rather high and the white count was 140,000. The possibility of liver extract playing a rôle in the child's improvement seems too remote for consideration for, of course, in all probability its use was coincidental with an attempted reversion to normal on the part of the hematopoietic mechanism. Yet, it is conceivable that some factor or factors in the body may be essential to prevent an uncontrolled over-production of certain blood cells just as the factor which is known to be present in liver extract is essential to initiate and sustain a state of normality in red cells where, one might say, under-production exists. The premise of a system of checks and balances in a blood cell controlling mechanism or mechanisms, which, in the normally functioning human body, prevents a shift toward abnormality in either direction is not without logic. There being at hand no other preparation which might conceivably provide whatever it was, if anything, that was lacking in this instance, liver extract was selected. Thus, I tried to justify submitting this already unhappy child to the additional discomfort of liver extract injections.

From about April 1 to April 9, clinical improvement was steady, being most marked the first five days following March 30. The nodules continued to disappear, although more slowly. Nodules known to exist one day would have disappeared entirely the next. The large temporo-parietal mass became hardly palpable. The

(Continued on Page 527)

MEDICINE IN WASHINGTON AND CHISAGO COUNTIES

ONE of the upper tributaries of the Mississippi is the St. Croix River, which forms part of the boundary between Wisconsin and Minnesota. It is also the eastern boundary of Washington and Chisago Counties. In the past it was the only approach to this region. Explorers, voyagers, and missionaries traveled its waters as it was one of the routes between the Mississippi and Lake Superior.

Until the treaties of 1837 with the Sioux and Ojibway Indians, there were few, if any, white settlers along its banks. White men knew the valley as a place of danger and the Indians referred to it by the ominous name of the "Valley of Bones," due, no doubt, to the frequent encounters then between the two hostile tribes.

With the signing of the treaty, the St. Croix valley was open for settlement. Lumber was the incentive which attracted the white man, and with the coming of the lumberman, medical history of the region begins. Among the first to arrive was a Dr. Fitch. In 1837 he and a group of others, including Franklin Steele, Jeremiah Russell, and a Mr. Maginnis, came from Fort Snelling and built a rough cabin near the falls. They then separated to search for pine, Dr. Fitch exploring the Sunrise River. A year later Dr. Fitch returned in association with the St. Croix Lumber Company. No other information about him is available except that he is said to have come from Galena, Illinois. Scarcely more is known about a Dr. Green, who came up the river in the fall of 1838, also looking for lumber. Green and his companions returned the following spring with complete materials for a mill, and on April 27, 1839, they drove in their stakes and formed at Marine the first permanent settlement in Minnesota. The mill was completed and at work by fall. Green remained at least two years, cutting timber near Kettle River. It is doubtful whether either Fitch or Green practiced; if they did it was probably incidental, for it was evident that their prime interest was lumber. This doubt is verified by the fact that all the early records speak of Dr. Christopher Carli, who came in 1841, as the first practicing physician north of Prairie du Chien. Dr. Carli's history is more complete than that of his predecessors.

Dr. Carli was born at Frankfort-on-the-Main December 7, 1811. He was educated at Heidelberg University, where he studied medicine. In 1832 he came to this country and practiced for three years in Buffalo, New York, before returning to Germany. However, after two years he again came to America, this time spending a year in Chicago, then a year in New Orleans, then going back to Chicago again. On May 24, 1841, he settled in Dakotah, St. Croix valley, on the site that is now Stillwater. His practice extended from Lake Pepin to Lake Superior, and from Menominee, Wisconsin, westward. He was always ready to visit a patient, on foot, skates or snowshoes, by horse or birchbark canoe. He was a member of the first city council of Stillwater and officiated as city and county physician, and coroner. He opened the first bank in Stillwater, and started the first drug store, which he afterwards sold to Dr. Henry Murdock. He also opened a stone quarry, dealt in real estate, and had many other avocations, for, like most of the pioneer physicians, he

was obliged to rely on something besides his profession for his support. He lived in Stillwater until his death in 1887.

As more settlers came to the valley another physician, Philip Aldrich, arrived. He was born in 1792. There is no record of his early life or education. He came in the early forties and was mail carrier for the entire valley. At different times he brought mail from Prairie du Chien and Fort Snelling, going as far as the falls and treating patients along the route on every bimonthly visit. Whether he had ever earned the title of Doctor or not, he performed the duties of physician wherever he was able. He was a prominent citizen and occupied many public offices, including judge of probate and justice of the peace. He donated land for the town of Buena Vista. Although a Wisconsin man, he was well known and active on the Minnesota side of the river.

The next newcomer, Dr. J. M. Covey, also settled at Stillwater in 1844. He was a regular physician, having received a medical education in his native state of New York. He is described as being a sociable but eccentric man, and slightly deaf. He died in 1851 supposedly from the effects of sleeping in a newly plastered room. In 1846 and 1847 two more physicians arrived about whom practically nothing is known. The first was a Dr. De Witt, who located at St. Croix Falls, and the other a Mrs. Page, a practitioner of the Thompsonian school at Hudson. At the close of the Mexican war came Dr. Otis Hoyt, who stayed at St. Croix Falls until 1851, practicing medicine and "delivering pleasing lectures on the Mexican war," in which he had served. He also practiced a year in Stillwater, then moved to Hudson, where he remained until his death in 1885. He was the most prominent physician in Western Wisconsin for many years.

One other physician arrived in the forties, a Dr. Wright, who settled at Marine in 1849. Nothing is known about him except that he died there in 1851. It is interesting to know that he was reported to have died of cholera. Since Asiatic cholera occurred at Stillwater about that time, it is possible that it also reached Marine, brought by the river boats. Dr. Wright is referred to as the first physician at Marine, which adds to the belief that Dr. Green never practiced there.

During the next decade a tremendous number of immigrants poured into the valley, and with them the necessity for more medical care increased. Epidemic and other diseases, new babies, the treacherous current of the river, the knives that were freely drawn in the saloons, and the frequent accidents with the dangerous circular saws of the lumber mills conspired to provide a steady stream of patients, and doctors arrived in rapid succession to fill the need. Drs. Pugsley and Ahl came to Stillwater in 1850, and in the years from 1854 to 1857 they were joined by Drs. Murdock, Noyes, Muller and Rhodes. Marine became the home of Drs. Cooley, Reiner and Gaskill, and in 1854 Dr. L. B. Smith, the first resident physician of Chisago County, settled at Taylors Falls. Smith had spent a year in St. Croix Falls (the town directly across the river, in Wisconsin), where even on the day of his arrival he found a patient waiting for him, a man who had been caught in a running saw, and whose arm was badly mangled. Amputation was necessary, but unfortunately the baggage which contained the doctor's larger instruments had not arrived, having been sent on a slower steamer. The operation was, therefore, performed as well as possible with a few small pocket instruments and a crude joiner's saw, and it is recorded that the patient recovered quickly. Smith was followed in 1855 by Dr. E. D. Whiting, who many years later married the widow of Dr. Smith.

Also in 1855 came Dr. E. W. Johnson of Lakeland, and Dr. J. W. Comfort of Wyoming. All of these physicians remained for many years and were prominent in their profession as well as in other activities.

Dr. H. W. Murdock's drug store, which he purchased in 1854 from Dr. Carli, appears to have been a busy place at this time, for many advertisements appear in the *St. Croix Union*, the only newspaper published in Stillwater at that time. For example, the following appeared first on February 13, 1855:

PILLS, PILLS

Pills old and young, of all qualities, kinds and descriptions. Enough to physic the territory at

Murdock's City Drug Store

Later, the doctor added a full line of perfumery, patent medicines, pure wines and liquors "for med. or mech. purposes," cigars, a soda fountain, paper hangings, oil paints and dye stuffs. He took as his partner Dr. O. G. Babcock, who came in 1855. Babcock moved to Afton in 1858, remaining there until his death in the fall of 1870. Carli's many activities are suggested by advertisements in the *Union*. On August 25, 1855, he advertised a hotel for rent, and offered for sale hardwood, 50 wheelbarrows, a two-horse wagon, 250 barrels of lime, 1,000 bushels of corn, 250 bushels of oats and 50 barrels of flour. Hoyt advertised land for sale. Crandall and Babcock also had a drug store, as did Pugsley and Reiner. These latter two were partners in practice at that time, as were Carli and Noyes. Later both partnerships were dissolved. In 1858 Pugsley formed a partnership with a newcomer, a Dr. Harlow. This partnership also was discontinued after several months. Apparently it was the custom for a newcomer to associate himself with a physician already established until he became known to the community.

In politics, in the forming of towns, and in the civic activities of their communities, many of the physicians played a prominent rôle. Reiner was a state senator; Gaskill a member of the first legislature. Reiner and several others served on the school board. Carli and Murdock helped organize the Stillwater fire department. Gaskill served three years as supervisor of the town of Marine. Later he was elected councilman, then elected and re-elected president of the council, and when Marine became a village he helped draft the charter. He was also a trustee of the state prison. Whiting was a representative in the legislature, and Carli was chosen president of the Old Settlers Association. Nearly all the doctors served as county, city or prison physician.

There is little information about diseases and epidemics in the earlier years of the settlements. The usual troubles were all present: tuberculosis, typhoid, scarlet fever and diphtheria. Asiatic cholera also reached Stillwater, carried there by the river steamers. Two interesting interviews with oldtimers are worth quoting in this connection. The first, Captain Stephen Hanks, of Albany, Illinois, remembered the cholera quite well:

"In 1851 or 1853," he said, "when I was rafting logs from the St. Croix to St. Louis, four of my men died of cholera on the way down. Two were taken ill in the evening and were dead in the morning. We stopped at the sand point between Willow River and Catfish Bar and I furnished the wood for coffins and Bowles made them. We buried them about a mile and a half above Catfish Bar on the top of the bluff. The rest of my crew deserted at Willow River. . . ."

The other interview, with E. W. Durant of Stillwater, included the following information:

"When the cholera first appeared on the river we were much afraid of it, but later, although it became very common, we paid little attention to it. The cholera came in 1849 to 1851, and spread from New Orleans up the river. All boats carried cheap board coffins and buried those who died when they stopped to take on wood, at night, if possible. . . . Another time, on the steamer "Cora" on the way up we buried several and at Stillwater landed a family of whom several died. Again, I attended two men on a log raft at Stillwater. I saw them in the evening and called again in the morning; one man at that time had lost half his weight and was very filthy, lying in a pool of mucus and bowel discharge. He died shortly after sunrise. I think four or five of that family died on the same trip up. We landed a cholera patient at Prescott, but I saved him; I used to give them Perry Davis Pain Killer internally and rub it on externally as well."

There is no way of estimating the extent of communicable diseases, because if any records were kept, they have since been lost. While the newspapers carried some death notices they rarely mentioned the cause of the death, and even when they did it was often such a vague term as "inflammation" or "complication" or merely "fever." Not all deaths were reported. This may have been due to the lack of news value in most cases, but it was evidently also due, in part, to a sense of civic pride which led the editors of the papers to deny any lack of health in their own communities. Epidemics were often reported by the papers of another town, but denied by the citizens of the town in which the epidemic was reported. It is hard to tell which was correct. However, deaths of a more sensational nature—fights and accidents—were often recorded. The latter were amazingly frequent, especially in the sawmills. Probably the mills had no safety devices then such as they have now, or possibly the men were careless; certainly the fast-running saws made an appreciable cut in the life and health of the community. One physician alone, in later years, reported five such injuries in three weeks.

The close of the decade of the fifties found the following physicians practicing in Washington and Chisago Counties: in Stillwater, Ahl, Carli, Dyson (a homeopath who came in 1858), Harlow, Muller, Noyes, Pugsley and Rhodes; in Marine, Cooley, Gaskill and Reiner, although the latter had spent two years in Stillwater; in Taylors Falls, Smith and Whiting, and at Lakeland, Dr. E. Johnson.

The next few years of medical history were much concerned with the Civil War, for many practitioners left to accept military positions. Some were killed; some settled elsewhere when the war ended; some stayed in the army. In 1861 Dr. Muller took an appointment as surgeon at Fort Ridgley. In April, 1862, Dr. Reiner was sent to Kentucky by Governor Ramsey to help care for the wounded. Dr. Reiner returned in May with "encouraging accounts."

The *Stillwater Messenger* for September 2, 1862, published the announcement that Dr. E. G. Pugsley was to leave, having been appointed assistant surgeon of the First Minnesota. On May 5, 1863, Dr. C. P. Garlick was appointed assistant surgeon of the Fourteenth Wisconsin Regiment, and in July, Dr. L. B. Smith was appointed an assistant surgeon, and left in April, 1864. Dr. Rhodes, in July of that year, obtained a situation in the Post Hospital at Memphis. He later became surgeon in a Minnesota regiment.

In the *Stillwater Messenger* for October 11, 1864, a note appeared that E. G. Pugsley, who had returned honorably discharged in February, 1864, had become assistant suregon in the Ninth Regiment. Pugsley built up an extensive practice in Glasgow, Missouri, though he never went back there after the war. Dr. L. B. Smith of Taylors Falls was killed the day before the battle of Tupelo, the division to which he belonged having been ambushed by Forest's troops. Smith

"was a tall man of fine personal appearance, with the air of an officer, for which reason, doubtless, some sharpshooter singled him out for destruction."

A Dr. H. M. Patterson died, although the war was only indirectly the cause of his death. The *Stillwater Messenger* for February 12, 1868, carried the following announcement:

> "Dr. H. M. Patterson died on Sunday morning, a victim of a disease contracted during the late 'cruel war.' A boy in appearance, he was a man in soul. We knew him for years in the military, and during the past eighteen months we have met him almost daily in the civil walks of life. He was a promising young man of twenty-six years, proficient in his profession and the soul of honor and generous impulses."

There is practically no other information about Patterson—when he came or where he practiced.

Dr. Muller apparently never returned to practice in Stillwater, though he visited the town occasionally. Most of the other physicians did return, however, to the valley.

Besides serving in the army at this time, the physicians took an active part in both local and state affairs. At a meeting of the board of county commissioners in September, 1862, Gaskill was appointed county examiner of school teachers in the first district. In February, 1863, Noyes was appointed prison physician. Drs. J. B. Phillips and E. D. Whiting were mentioned as being at a legislative district convention at Marine in September, 1866. In April, 1868, there was a notice in the Stillwater paper by J. R. M. Gaskill, district clerk, and in August and October the *Taylors Falls Reporter* announced that Drs. Marshall and Griswold had been appointed examining surgeons for pensions. The next year some mention is made of "Senator Dr. Noyes." Whiting served in two sessions of the Minnesota state legislature (1860-1861) as a representative. Rhodes was also very prominent in civic affairs at this time.

Political activities were not the only ones in which the doctors took part. Christopher Carli advertised himself as a banker and broker. Ahl ran a hotel. Whiting made an extensive trip through Europe in 1867, visiting the Paris exposition and stopping at all the principal cities of the continent. In 1869 Rhodes invented and patented a very useful "spark-catcher" for the draft of parlor stoves. The same year a young men's course of lectures was planned, among which was one by Dr. A. J. Stone on "The Physical Education of the Coming Man," and one by Dr. Reiner on education. Dr. Kinkle was to have spoken, but was too busy at the last moment. Dr. Stone at this time issued a prospectus for a medical and surgical journal which appeared in Saint Paul a year later, in June, 1870. It was a monthly magazine called *The Northwestern Medical and Surgical Journal.* Stone was both editor and proprietor. Three Stillwater physicians were among those who, in 1869, formed the State Medical Society; they were Rhodes, Noyes, and Stone.

Among the newcomers of this decade were several very reputable practitioners as well as many disreputable ones. In 1860 came Dr. Hiram Murdock, the father of Dr. H. M. Murdock, who had been practicing in the valley for several years, and of Dr. G. W. Murdock who came to Taylors Falls in 1865. Hiram Murdock originally practised at Stillwater, but moved to the Falls in 1862, and stayed there until his death four years later. In 1861 Dr. G. M. Lambert came to Stillwater and in 1862 Dr. George Taylor to Point Douglas. In 1862 we find the following newspaper item:

EYES, EYES, EYES!

> Dr. J. A. Gilison, operator on the eye, will make a short stay in Stillwater at the Sawyer House . . .

Gilison highly recommended himself, offered to cure any ailment presented, and advertised "no charge for examination or opinion." He returned frequently to Stillwater and was typical of a large group of doctors who traveled from town to town, leaving behind a trail of useless medicines and valueless advice. In 1865 came Dr. C. A. Brooks, formerly an army surgeon, and the above mentioned Dr. G. W. Murdock. A peculiar and unfortunate event marked the arrival of Dr. Brooks. His first call, the day after his arrival in Stillwater, was to return to Minneapolis to attend his brother, who had been accidentally and fatally shot. In 1866 several physicians arrived. Drs. Marshall, Griswold and Spicer all came to Taylors Falls and settled there; also, the papers mentioned Dr. J. B. Phillips of Marine. In 1867 and 1868 a Dr. Carrington practised at Taylors Falls, and Dr. N. W. Beckwith, an eclectic, and Dr. H. Runge came to settle in Stillwater. Runge had a rather varied career. Born in Germany in 1817, he went to school in Russia, and graduated after a six-year course in the University of Berlin. He then studied to become a veterinary surgeon in Copenhagen for two years. After that he returned to Moscow and practised until 1863. Then he went to South America and later to Iowa, where he stayed until 1867, when he came to Stillwater. Later he spent eight years in Minneapolis, returned to Stillwater, and in 1880 settled permanently at Osceola. In 1868 Dr. Garnet spent the summer in Taylors Falls; and Dr. W. H. Cavin, formerly of Hudson, moved to Stillwater. In 1869 Drs. A. J. Stone, G. W. Hart, and J. C. Kinkle settled in Stillwater, and in 1870 Drs. Jordan, Morrow and A. J. Murdock began to practise in the valley, the latter at Taylors Falls. Some of these newcomers formed temporary partnerships with other physicians. Among these partnerships were Gaskill and Brooks (at Osceola), Kinkle and Noyes, Stone and Jordan, Spicer and Griswold.

With the coming of more physicians to the St. Croix valley, it was natural that some sort of a medical society be formed. There is no record of when the first one was formed, but in the *Stillwater Messenger* of May 27, 1862, the following brief announcement appeared:

> "The next quarterly meeting of the St. Croix Valley Medical Association will be held at Hudson on the 27th day of May, 1862, at 10 o'clock A.M. Surgical operations will be performed and advice given gratuitously for those who choose to present themselves before the association."

Evidently, then, there was some sort of medical society at the time, although there is no other record of its activities. It must have broken up later, probably due to the comings and goings of the physicians during the war, because in 1871 there were attempts to form a new organization.

The general health of the people in the counties during these years was poor, and epidemics were constantly being reported. Diphtheria was an ever present cause of worry; a large percentage of deaths reported in the papers were attributed to it. In March, 1863, the *Messenger* reported that "the dreadful disease prevails to a considerable extent in Hudson, having caused several deaths there." The same item recommended the use of ice, broken into small pieces and swallowed by the patient at intervals "until relief is experienced." Among others, one of Dr. Carli's daughters died of the disease in January of the following year. The Taylors Falls papers, in February, 1860, reported the disease prev-

alent, and stated that several children there had died of it. As to smallpox, in May, 1864, the Stillwater paper reported as follows:

"We are reliably informed that this dreaded disease has made its appearance at Marine, having been brought to that place by a young man from Fort Snelling. When he was first taken down, it was not known to be smallpox, and many of the friends and neighbors called in to see him, thus spreading the contagion in an alarming manner. We have no further particulars. Our people would do well to take every precaution to guard against the disease as we can hardly hope to escape a visitation of the dreadful scourge."

Apparently it did not immediately spread to Stillwater, although early in 1870 it was said to be "all around." Ten or twelve cases were reported at the Falls, thirty or more in the vicinity of Prescott, and one light one, the first in eight or ten years, in Stillwater. The Taylors Falls papers reported seven cases in Osceola (on the Wisconsin side of the river), most of them mild, but one fatal. The schools there were closed because of it. The paper also quoted Dr. Carli as saying that it could be checked in a short time by vaccination, diet and quarantine. Apparently there was some attempt to isolate cases at this time, although it was not strict enough to stop any epidemic. Among other diseases, the chief ones mentioned were lung fever and hydrophobia. The *Messenger* of January, 1867, remarks: "Our physicians say that there is more sickness in this place and vicinity at this time than ever before known. The prevailing disease, which has assumed an epidemical type, is lung fever." Curiously enough there were actually no cases of hydrophobia reported, although there were constant complaints and much fear of unmuzzled dogs. One death from cholera was reported in August, 1863, a few miles from Stillwater, and measles and other less serious epidemics made their appearance.

Statistics concerning the diseases in the state prison at Stillwater at this time are available, and show fairly well the frequency of illness in that institution. In 1866 there were nearly two cases of sickness to every prisoner; in 1867 over five; in 1868 over six; and in 1870 over four. The number of convicts at the beginning of the year 1867 was only thirty-five; at the beginning of 1868, forty-five, and at the beginning of 1869, forty-two. Conditions in the prison gradually became better after 1868, there being fewer illnesses per prisoner, although of course more prisoners. On reading reports of the prison at this time one's greatest surprise will probably be that there was not more illness and a much higher mortality rate. While the food was generally agreed to be excellent, and some sanitary regulations were strictly enforced by the warden, nevertheless the ventilation, heating, toilet facilities and especially the drainage were very poor. Even several years later, when the Board of Health made its first report, the site was described as unfavorable; the soil about the prison was saturated by springs; stagnant water covered the prison yards at all times, making the lower walls damp. The lower tier of cells was untenable, having two inches of water standing on the floors, and the walls bulged noticeably and "might fall at any moment." The well in the yard was muddy from surface drainage. The privy was described as being in a filthy condition, and refuse from the kitchen was simply thrown out in the yard. The air was damp and musty, and the cells were ventilated only by four-inch openings into an air shaft, which most prisoners closed up in the winter because of the inadequacy of heating. The cells were only five by seven feet. Of course, the prisoners worked from six to six, with only a half hour for lunch, or, in winter, from five to seven, but they spent the rest of their time in these cells, eating and sleeping in them. The dark cells, for refractory prisoners, were "offensive and not properly ventilated," and the cus-

tom of chaining misbehaving convicts to the doors, in a standing position, prevailed. Besides these, later reports by prison physicians and inspectors reported bathing facilities most primitive, laundry arrangements poor, and the kitchen very poor, though the food was good. The hospital was inadequate and in many cases sick prisoners had to be treated in their cells. In 1876 the prison physician was still urging that a sewer be built, as there had never been even the most primitive one. He urged also that a competent medical graduate be employed as hospital steward, as the position was then filled by an incompetent convict. In 1877 the prison was so crowded that some of the five by seven cells held two convicts. It would be highly unfair, however, to blame prison officials for the poor conditions, as they were simply an echo of conditions in most of the towns at that time. Stillwater itself was far from modern in sanitary ideals. The average person at that time was quite ignorant, and new ideas were probably hard to introduce. For example, in the *Taylors Falls Reporter* in the spring of 1866, there appeared an excellent article on trichina, with illustrations, by a Chicago physician. In the following issue of the *Reporter* appeared a long comment on "the atrocious trichina story," saying what a hoax and fraud the former article was, that trichinosis existed only in a certain small part of Germany, where pork was eaten raw and uncured, and it was caused by the diet of the hogs, which ate snakes and vermin. The article assured its readers that trichinosis was never found in the corn-fed hogs of the surrounding territory.

When the decade closed, the following physicians were in the two counties: Ahl, Brooks, Carli, Gaskill, Griswold, Kinkle, Lambert, Marshall, Morrow, A. J. Murdock, Noyes, Reiner, Rhodes, Runge, Spicer, Stone and Whiting. Probably Drs. Beckwith, Cavin and Dyson should be included, although there is no further record of either their presence or their departures. Babcock and Jordan had both died in 1870; Johnson left in 1864, Geo. W. Murdock in 1868, and Hart in 1870. Muller and Pugsley both settled elsewhere after the war; Smith was killed, and Taylor of Point Douglas left after a year. The *Reporter* of February, 1870, said that there were only eleven licensed physicians in the district, which included Washington, Chisago, Pine and Kanabec Counties. In Washington County, in 1869, according to the report of the committee of credentials in the State Medical Society, there were four regular and five irregular practitioners.

Clinico-Pathological Conferences in Hospitals

THE Council on Medical Education and Hospitals of the American Medical Association is charged with the duty of the certification of hospitals for the training of interns and resident physicians. This is what it says about one feature of its requirements:

"Necropsy performance in hospitals has rightly become a criterion of the scientific attitude of the staff. It reflects a desire to elevate the practice of medicine, an eagerness for scientific accuracy and a recognition of pathology as a sound basis on which to build clinical knowledge. To interns and older physicians alike there is a steady accrual of knowledge through repeated postmortem studies *in which pathologic and clinical manifestations are carefully correlated.*"

"To comply with the requirements of the Council a hospital approved for intern training must maintain a necropsy rate of at least 15 per cent of its deaths in order to supply an adequate amount of teaching material for the instruction of the house staff. *Surgical as well as necropsy specimens can be used to advantage in clinical pathological conferences, which should be conducted weekly or biweekly in accordance with the amount of material available.*" (The italics are ours.)

(J.A.M.A. 110:974, March 26, 1938.)

Again, the American College of Surgeons is responsible for the accrediting of hospitals for standardization and here is clause (b), section 3 of its Minimum Standard for Hospitals:

"That the medical staff review and analyze at regular intervals their clinical experience in the various departments of the hospital, such as medicine, surgery, obstetrics and the other specialties; the medical records of patients, free and pay, to be the basis for such review and analysis."

(Am. Coll. of Surg. 1938 Year Book, p. 57.)

So much for what may be called the letter of the law. There are additional reasons why clinico-pathological conferences have become necessitous. In private or voluntary hospitals, for instance, the opportunities for teaching interns and giving them a chance to put what knowledge they have acquired into practical application are very much less than in the larger public institutions, consequently positions in the latter type of hospital are much more sought after and the private hospitals have difficulty in securing their interns. Having done so, however, are these private hospitals not obligated morally to make up, as far as they possibly can, the deficiencies in their teaching and clinical opportunities for their interns? Certainly they are, and in no better way can they do it than by carrying on well planned conferences. Every hospital has an abundance of material, in both the living and the necropsy fields, and it is the duty of every staff, we believe, to see that such material is made available and presented properly each week. If the hospital has a full-time pathologist who is capable of taking charge of it, so much the better, but sometimes the hospital's internal arrangements point to the wisdom of a different plan, with a well informed

clinician looking after it. This arrangement is in effect in the oldest and best known hospital clinico-pathological conference in Minnesota. At another hospital a very successful conference has been carried on for several years by the roentgenologist. In both instances the pathologist collaborates very capably. In all cases the interns should be required to attend regularly and their duties so arranged as to permit them to do so. They should participate in the work themselves to a measurable extent. In one hospital conference they are required to make up the abstracts of the cases to be presented and read these themselves, then the staff members who have been connected with the cases amplify the findings and discuss them, following which a general discussion is carried on.

In any hospital where a conference of this type has been successfully established we believe that the morale of the staff is improved. Free discussion of difficult clinical problems, either in living patients or from those which have come to necropsy leads to clearer understanding and greater confidence between its members and to the creation of a better atmosphere in all the hospital's activities.

Finally, and most important of all, the entire quality of professional service in a hospital where its clinical and pathological problems are attacked at close range by its staff in a body is benefited and elevated. To know that the details of any case in the hospital may be utilized at short notice for full and open discussion in these conferences stimulates effort on the part of any who may be concerned. Closer attention is given to the verification of entries in the record and omissions are made up; more care is taken in the history writing and not seldom is the literature consulted, if there is any probability of a case being presented in conference. The work of the interns is scanned more closely and they themselves are found to take keen interest in having their notations above criticism. They seem to enjoy these conferences, too, and make no effort to stay away from them, once they have learned their value. As for the staff, it is their opportunity. They can make these conferences agreeable, profitable occasions if they will. Invariably, experience shows that the busiest and best trained men on staffs are the most regular attendants. They contribute freely of their time and ability and get much in return. It is this that builds up and maintains the spirit of these undertakings and makes them indispensible.

Vitamin K

IN 1935 Henrik Dam reported the isolation of a material, deficiency of which in the diets of chicks resulted in fatal hemorrhage. He found this fat-soluble material in pig liver fat and designated it vitamin K. Subsequently, this compound was prepared in concentrated form and recently has been crystallized by Almquist. Thus, in a short time, another apparently essential animal nutritive product has been recognized and some of its basic chemical properties determined.

So-called vitamin K apparently is distributed widely in nature. In the plant kingdom its distribution appears to be confined almost entirely to the photosynthetic portion of the plant and in this its distribution is radically different from that of provitamin A. Considerable amounts of vitamin K have been found in alfalfa, kale, spinach, dried carrot tops, chestnut leaves, tomatoes, oat sprouts, and many other plants. In addition, it is found in soy bean oil and in the unsaponifiable portion of dog liver fat and pig liver fat.

The vitamin can be prepared from fish meal, rice bran or casein after the ether extracted material has been allowed to putrify and then subsequently extracted with petroleum ether. Under these conditions it appears that bacteria may cause the synthesis of this material but just what organisms can accomplish this synthesis are not as yet definitely known. However, Almquist and his associates recently have isolated a "fish meal organism" which closely resembles Bacillus cereus and which contains, and is capable of producing in fish meal, considerable amounts of vitamin K. The vitamin also is present in the droppings of chicks, in dried normal acholic feces of man, in dried colon bacilli, Bacillus subtilis, Staphylococcus aureus and many other microörganisms. Presumably the vitamin is present in the lipoid fraction of these bacteria but further data will be necessary before it can be assumed that the vitamin K found in alfalfa is the same substance as that present in microörganisms.

The exact physical and chemical properties of vitamin K are at present incompletely known but some properties seem to be definitely established. Physically it is a colorless, crystalline, fat-soluble material which is stable in air at 120° C. but is rapidly destroyed by alkali or sunlight. The substance apparently has a high molecular weight and contains a small amount of nitrogen but no sulfur or phosphorus.

Among young chicks which are given diets deficient in vitamin K there develops a tendency to bleed which is somewhat in proportion to the deficiency of prothrombin in the circulating blood. The syndrome in chicks is characterized by bleeding from the pin feathers and hemorrhages into muscles under the skin and in the abdomen, together with dark erosions on the lining of the gizzard. Frequently, low levels of hemoglobin are present and not infrequently fatal hemorrhages may develop very suddenly. Administration to these chicks of materials which contain vitamin K results in cessation of bleeding and an accompanying rise in the level of prothrombin. These phenomena are the basis for all known biologic assays of vitamin K.

The available experimental data are too meager to justify offering an explanation of the mechanism by which vitamin K affects prothrombin. Although prothrombin, so far as is known, does not contain a lipoid component, the possibility is not excluded that vitamin K, or a derivative thereof, might be present as a prosthetic group which is held in firm combination with the rest of the prothrombin molecule.

The recent demonstration that in the circulating blood of individuals who have jaundice there is a deficiency of prothrombin, has led to the clinical use of vitamin K as a therapeutic aid in the prevention and control of this abnormal bleeding. Independently, several groups of investigators have reported the successful elevation of the prothrombin level and in some instances inhibitory effects on actual bleeding of individuals with jaundice.

These results give some hope for control of the hemorrhagic diathesis in jaundice. However, simpler methods for estimation of the level of prothrombin in the blood and a more easily available and at the same time nearly chemically pure source of vitamin K are much needed at present. The recent successful use of injectable concentrates of vitamin K gives hope of standard dosage and of a standard method of administration.

The A.M.A. Meeting

THE eighty-ninth annual session of the American Medical Association at San Francisco was outstanding in many respects. The attendance was large considering the location, approximately 6,000 registrants. As usual in recent years, much time was spent by the House of Delegates on economic questions. The president, Dr. J. H. J. Upham, in his address referred to the multiplicity of medical meetings and to the increasing growth in many localities of postgraduate courses, the demand for which appeared to be growing. He depreciated the lay control of scientific medicine and favored the campaigns on cancer, tuberculosis, and syphilis.

Dr. Irvin Abell, president-elect, was most enthusiastic over the excellent type of medical service now rendered to the American people, comparing the low morbidity and mortality here with that of other countries. He estimated that medical service rendered to the poor by American physicians amounted to over a million dollars a day. He said there should be no compromise between the profession and lay groups in the manner in which that service should be rendered. He also favored graduate extension.

President Wilbur of Stanford niversity stressed the need for more and better instruction for graduate and undergraduate students and suggested a three year pre-medical preparation for prospective students of medicine, adding that the quality of the applicant was of more importance than anything else.

Dr. Rudolph Matas of New Orleans was awarded the distinguished service medal of the Association. This is bestowed for outstanding achievement in Medicine and Surgery each year. Dr. Rock Sleyster of Wisconsin is the new president-elect.

Dr. H. H. Shoulders of Tennessee was elected Speaker of the House of Delegates succeeding Dr. Nathan B. Van Etten of New York.

Dr. Austin Hayden of Chicago and Dr. C. B. Wright of Minneapolis were each elected to succeed themselves as trustees for the ensuing five years.

The technical exhibits were many and varied. The scientific exhibits were generally considered very good but hardly the equal of the past few years.

Meeting places for the next three years were selected as follows: St Louis, Missouri—1939; New York City—1940; Cleveland, Ohio—1941.

The Duluth Meeting

THE annual meeting of the Minnesota State Medical Association held at Duluth, June 28 to July 1, was one of the most successful in the history of the Association. The program throughout was exceptionally interesting. Those in charge of the program were fortunate in obtaining a number of noted men from outside the state, among them being Dr. Howard W. Haggard of Yale University, and Dr. Irwin Abell, president of the American Medical Association.

Dr. George A. Earl of Saint Paul, the president-elect, will succeed Dr. J. M. Hayes at the end of the calendar year. Dr. J. C. Jacobs of Willmar was chosen first vice president, and Dr. A. M. Hanson of Faribault, second vice president. Dr. B. B. Souster of Saint Paul was elected secretary, succeeding Dr. E. A. Meyerding. Dr. W. H. Condit was re-elected treasurer.

Dr. H. Z. Giffin of Rochester was elected chairman of the Council. Dr. L. L. Sogge of Windom was re-elected to the Council from the Second District; Dr. B. S. Adams of Hibbing was re-elected from the Ninth District, and Dr. E. Mendelssohn Jones of Saint Paul was elected from the Fifth District, succeeding Dr. George A. Earl. Dr. W. A. Coventry of Duluth and Dr. W. F. Braasch of Rochester were re-elected delegates to the American Medical Association.

Dr. W. W. Will of Bertha was re-elected speaker of the House of Delegates. Dr. E. A. Meyerding, who has retired as secretary, was elected vice-speaker of the House of Delegates, and was presented with a gold medal for distinguished service to the Association over a period of many years.

The next annual meeting will be held in Minneapolis.

In Memoriam

Henning F. B. Wiese

1889-1938

DR. HENNING F. B. WIESE was born June 17, 1889 at Nordfjord, Norway, the son of Christian and Johanna Wiese. He was the youngest of seven children. His paternal great grandfather and grandfather were physicians in Norway. His maternal grandfather and one uncle also practiced medicine in Norway. His father was an expert accountant. One of his brothers is a physician in Norway and a sister is married to an English physician who resides in Paris, France.

Dr. Wiese attended the Gymnasium at Oslo, Norway, from 1904 to 1907, after which he entered the University of Oslo, graduating in 1915 with the highest honors of his class. He served his internship in the Rikshospitalet in Oslo, at the end of which time Dr. Mathiesen of Eau Claire, Wisconsin, who was Dr. Wiese's godfather, invited him to spend some time with him and Dr. Midelfart in their clinic, which he did, staying one and one-half years. From there he entered the Mayo Foundation at Rochester, Minnesota, where he spent three years. He was called by Dr. Schilling, the chief surgeon, to the Ullevaal Sykehuse in Oslo, Norway, at which hospital he served as surgeon for two and one-half years.

He received the degree of Master of Science in Surgery in 1922 from the University of Minnesota. He was a Fellow of the American College of Surgeons and the American Medical Association and a member of the Minneapolis Surgical Society. He was a member of the Kristiania Surgical Society and the Norwegian Medical Society; also a member of the Alumni Association of the Mayo Foundation.

During the World War Dr. Wiese held the commission of First Lieutenant in the Medical Reserve Corps and the heavy artillery of the Norwegian Army.

He gave his services for many years to the Wells Memorial Clinic and the Ebenezer Home. and he was a member of the Surgical Staffs of Asbury, Swedish, Fairview and Deaconess Hospitals.

Dr. Wiese was married on December 16, 1922, to Juanita Wood, daughter of Frederick and Fanny Wood of Eau Claire, Wisconsin. They have two children, Karin, age 14, and Stetson, age 11.

Above all else Dr. Wiese loved his family and his home, and it was his desire to remain there throughout his final illness, which lasted seven months. It was my privilege in association with Dr. Charles Hallberg to see him a great deal in the final weeks of his illness and to note the faithfulness with which his beautiful and talented wife cared for him. He was brave, patient and considerate of others to the end, which came at noon, Friday, April 29, 1938.

Dr. Wiese was one of the most ethical surgeons

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
W. F. Braasch, M.D., Chairman

State Meeting

The Minnesota State Medical Association was holding its 85th Annual Meeting at the Hotel Duluth in Duluth as this issue of MINNESOTA MEDICINE went to press.

See the August issue for a complete résumé of events of this meeting.

AT SAN FRANCISCO

It is probable that there were more interested lay spectators in all parts of the country than ever before when the House of Delegates of the American Medical Association met in San Francisco in June, 1938.

Since the eventful session of 1937 in Atlantic City, the celebrated controversy, so-called, between the American Medical Association and the Committee of Physicians with their 430 signers broke into the headlines. Medical policies and plans—once "caviar to the general"—abruptly became front page news, along with strikes, mobbings, elections.

The floodlight of publicity seldom reflects facts with anything like a scientific accuracy. The rank and file of physicians saw themselves aligned there with that quaint survival of another day, the "stand patter," and were naturally astonished and resentful.

It was natural too, perhaps, that the proposal made some time ago by which the physicians should organize and go into the propaganda business for themselves should gather momentum as a result.

Better Counsel

Fortunately, better counsel prevailed at San Francisco. The American Medical Association will not organize a bureau after the pattern of meat packing interests, the soap interests, the patent medicine interests, the liquor interests.

The spectacle of a publicity bureau financed by doctors, complete with slogans, contact men, expense accounts and high powered advertising experts is unappetizing, still, to the majority of doctors. They have no skeleton to hide, no pork barrel to roll over. They want to take care of sick men to the best of their ability and they want to help well men to stay well. In the process, they wish to earn a sufficient income to provide for their families. Of the two objectives they are probably just a little more interested in taking care of the sick than they are in providing a livelihood—and that is a special distinction they hold over many other professional and business men.

Unnecessary Luxury

There seems to be very small reason for such men to indulge themselves in the modern luxury of a gigantic publicity bureau and advertising campaign.

The advantage to be gained, even in modern America, which operates to some extent through a nice balance, made up of horse trading and manipulation between pressure groups, would probably not be worth the effort. It might, in fact, produce a grave and unfortunate reaction and the expense involved would be terrific. In fact, the demand for funds for the new venture might well eat into the great services to the public for which doctors are justly proud—their machinery for protecting medical education, their great Councils, their public health education.

The resolution which rejected the proposal of three states was definite, though it suggested, by way of gesture, to those who clamored for a new relation to the public and press, that all spokesmen for organized medicine conduct themselves, in the Latin phrase, with "suaviter in modo" at the same time, they maintained the absolutely essential "fortitur in re." It passed without a dissenting vote.

No Split in the Ranks

Thus, the American Medical Association emerged from the storm and stress of another year without the split predicted in the headlines by the 430 episode; and it is still firmly established, as to public policy, upon the foundation of the famous ten principles.

One of the ten points was modified, it is interesting to note, to disapprove the inclusion of the special medical services such as pathological examinations, x-ray work and anesthesia in group hospitalization contracts and providing for removal of hospitals from the association's approved list where either the public or the profession is exploited.

The large number of hospital insurance proposals now being promoted publicly and privately made a specific clarification on these points essential and desirable.

For a Department of Health

The Federal Department of Public Welfare included in the recent government reorganization bill was condemned from the start by the House of Delegates. In its place, the delegates at San Francisco again approved a cabinet department of health which should be directed by a medical man as secretary.

It was appropriate and essential that the delegates should point out specifically that they—and not the special societies or individuals anywhere—are the truly qualified representatives of medical practitioners in America and that their actions in San Francisco reflect the policies and beliefs of organized medicine in the United States. Members of the house who are affiliated with other special societies were urged to work toward a closer coöperation between all medical groups in the country.

Survey

Dr. W. F. Braasch of Rochester, chairman of the Minnesota State Medical Association's Committee on Medical Economics and also chairman of the American Medical Association's advisory committee on the current nationwide survey of medical facilities, presented an encouraging report to the delegates. This survey will lay the first sound foundation for changes where they may be found necessary in the current system of handling medical care for the indigent or the low income groups, and will be complete within the year, it is hoped. It will constitute a great contribution on the part of American medicine to the social readjustments necessary to our time.

Members who visited the American Medical Association exhibit at Duluth found a complete progress report to date from Dr. R. G. Leland, director of the Bureau of Medical Economics of the American Medical Association, and in direct charge of the national survey.

Reëlection for another five years of Dr. C. B. Wright of Minneapolis to the Board of Trustees, of course, is gratifying to Minnesota.

ECONOMICALLY SPEAKING

[Monthly Editorial Prepared by The Medical Advisory Committee]

A survey of the present economic situation finds the business man generally viewing it with distrust. Everywhere dissatisfaction with today's set-up is apparent.

Many educators and parents are becoming resentful of the rather radical departure from the old fashioned teaching of the 4 R's and fundamental ABC's.

Ministers find a new alarm in the wandering away from the old time religion of our forefathers and a tendency in some nations to scoff at the teachings of the Church.

Lawyers view the promulgation of the totalitarian state with concern knowing that if the new tendency in thought is carried out, the law of the land may be that of the dictator.

Men of medicine see in the future possible abandonment of the patient-doctor relationship with all that it means, complete state controlled health service and its many possible dire results.

But your Medical Advisory Committee has noted with marked satisfaction during the last year a tendency for the approximate 2,500 members of our State Association to think more as a group than as individuals knowing that that which effects one effects all; that the malpractice cases are lessening in Minnesota, smaller verdicts are being obtained in courts, there are fewer professional testifiers in evidence. Our medical work is becoming more effective in the state, and we are better united with each other; therefore, the public is served better. Rural and urban lines are being eliminated.

Not Utopia as yet, but we are thankful for the few miles we have gained on the road to a better understanding. Your neighbor's trouble or

success reflects on you and should be your concern. A good neighborly spirit makes for contentment.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Non-medical "Interne" Pleads Guilty to Practicing Medicine without a License

Re: State of Minnesota vs. Halsted.

On June 1, 1938, Hugh David Halsted, twenty-six years of age, entered a plea of guilty in the District Court at Minneapolis, to an information charging him with practicing medicine without a license. Following a statement of facts to the Court, Judge Edward A. Montgomery, sentenced Halsted to one year in the Minneapolis Work House and placed him on probation for one year. On April 19, 1938, Halsted was tried before a military court at Fort Snelling on a charge of misrepresenting his rank as an officer and misrepresenting his qualifications as a physician. He pleaded guilty to both charges and was given a dismissal from the military service of the United States.

(Photo courtesy of Minneapolis Star)

The investigation conducted by the Minnesota State Board of Medical Examiners, which resulted in the filing of a complaint against Halsted by Mr. Brist on behalf of the Board, disclosed that Halsted was born September 29, 1911, at Milwaukee, Wisconsin. Before moving to Minneapolis, in the summer of 1929, Halsted resided in Chicago, and Chattanooga, Tennessee, graduating from high school in the latter place. From 1930 to 1933, inclusive, Halsted was a truck driver for the Harriet Laundry in Minneapolis. For a short period in 1934, Halsted worked as a shoe salesman for Dayton's Department Store. Along in the late summer and early fall of 1934, he spent some spare time at the Minneapolis General Hospital. Halsted stated that he always had a desire to be a physician and this prompted him to "hang around" the Minneapolis General Hospital. From October 10, 1934 to January 1, 1935, Halsted acted as an interne at Minneapolis General Hospital, according to a letter written by Dr. C. E. Remy then superintendent. From January 1, 1935, to June 25, 1935, Halsted was an interne at $50.00 per month at the Deaconess Hospital in Minneapolis. When inquiry was made at Deaconess as to why no investigation had been made of Halsted's credentials as a physician, the explanation was given that Halsted had previously been at Minneapolis General, and they assumed his credentials were in order. On July 5, 1935, after fraudulently representing himself as a physician and a graduate of the medical school at Northwestern University, and that he was licensed to practice medicine in Illinois, Halsted signed a contract to act as contract surgeon for the CCC Camps in Minnesota. No investigation was made at that time by those in charge to ascertain Halsted's qualifications. He was assigned to Camp No. 703 at Schroeder, Minnesota. In October of that year he was transferred to Allen, Minnesota. During the winter of 1935 and 1936 he was at Camp No. 724 at Bay, Minnesota. In the spring of 1936 he was transferred to Two Harbors, and subsequently to Rochester and Fort Snelling. In September, 1935, Halsted received a commission as a first lieutenant in the Medical Reserve Corps of the United States Army. This commission was obtained upon his fraudulent representations with respect to his medical training.

In September, 1937, Halsted "promoted" himself to a Captaincy in the Medical Reserve Corps. Following his marriage in 1936, Halsted was paid $262.00 per month by the Government. In February, 1938, inquiry was made concerning Halsted's qualifications as a physician which led to his court martial on April 19th. The only medical education that Halsted ever received was in the Extension Division of the University of Minnesota in the year 1930-1931, at which time he was enrolled in a class in General Inorganic Chemistry. In the school year 1931-1932, he was enrolled again in a similar extension course and the records indicate that he failed.

This case again emphasizes the necessity of more care being exercised by hospitals in Minnesota in the selection of their internes. Halsted violated the Medical Practice Act of Minnesota while he was at Minneapolis General, at the Deaconess Hospital and in the CCC Camps. At no time, during his career, did he have any right to represent himself as a physician and surgeon, nor to assume to act in that capacity. Judge Montgomery, in passing sentence, remarked that he did not understand how Halsted got by as long as he did. While he was at Fort Snelling, Halsted resided at 2284 Highland Parkway, St. Paul; at the time of his arrest he resided at 4039 Pillsbury Avenue, Minneapolis.

Minneapolis Drug Addict Sentenced to Ten-year Term for Obtaining Morphine by Misrepresentation

Re: State of Minnesota vs. Kathrine Burkhardt.

On June 8, 1938, Kathrine Burkhardt, 36 years of age, entered a plea of guilty to an information charging her with obtaining morphine by fraud, deceit, misrepresentation and subterfuge. She was sentenced by the Honorable Edward A. Montgomery, Judge of the District Court at Minneapolis, for a term of not to exceed 10 years in the Women's Reformatory at Shakopee.

The defendant, a drug addict, is the first person to be prosecuted under the Minnesota Uniform Narcotic Drug Act for obtaining morphine by fraud or misrepresentation. This law was passed in 1937 by the Minnesota Legislature and provides, among other things, as follows:

> "Sec. 18. Restrictions on obtaining drugs.
> (1) No person shall obtain or attempt to obtain a narcotic drug, or procure or attempt to procure the administration of a narcotic drug, (a) by fraud, deceit, misrepresentation, or subterfuge; or (b) by the forgery or alteration of a prescription or of any written order; or (c) by the concealment of a material fact; or (d) by the use of a false name or the giving of a false address.
> (2) Information communicated to a physician in an effort unlawfully to procure a narcotic drug, or unlawfully to procure the administration of any such drug, shall not be deemed a privileged communication."

The maximum penalty for a violation of the Act is 5 years imprisonment in a state penal institution. The defendant in this case received a 10-year sentence because she had two prior convictions for felonies in the United States District Court.

The Minnesota State Board of Medical Examiners was asked to coöperate with the Federal Bureau of Narcotics at Minneapolis in the prosecution of this case. The facts indicated that the defendant was an

addict and between March 26, 1938, and May 30, 1938, had obtained 19 prescriptions for a total of 233¼ grain morphine sulphate tablets from six Minneapolis physicians. She obtained these prescriptions by misrepresenting her physical condition and falsifying her name and her address. On being questioned by Judge Montgomery, the defendant stated that she was raised at Wabasha, Minnesota, and that her true maiden name was Katherine Mahoney; that her married name was Burkhardt and that she was divorced in 1926. She stated that she had been addicted to the use of morphine for the past 16 years. On being questioned by Judge Montgomery with respect to her physical condition she stated that she suffered from chronic asthma: that she had a tumor on her spine and that she suffered from adhesions following an operation. The defendant gave her true address as 1155-15th Avenue S. E., Minneapolis, where she resided with a sister.

The defendant used many aliases in obtaining these prescriptions, among them being the names of Barnes, Berg, Varnes, Fairchilds, Johnson and Peschkie. In 1933, the defendant was sentenced by Judge Nordbye in the Federal Court in Minneapolis, to a three year term in the Federal Industrial Institution for Women at Alderson, West Virginia. This sentence was imposed for a violation of the Harrison Narcotic Act. In 1936, the defendant was sentenced by Judge Joyce in the Federal Court at St. Paul for a 10 months term in the Minneapolis Work House for a similar offense The defendant also was in the Minneapolis Work House on four different occasions for vagrancy and once for the unlawful possession of morphine, in addition to the foregoing sentences in Federal Court.

The Minnesota State Board of Medical Examiners wishes to express its appreciation of the fine coöperation displayed in this case by the Federal Bureau of Narcotics in Minneapolis under the supervision of Mr. Harry D. Smith, and also the fine coöperation shown by Mr. Ed J. Goff, County Attorney, and his assistants Mr. Peter S. Neilson and Mr. Allen T. Rorem. The Medical Board believes that the enforcement of this particular provision of the Minnesota Uniform Narcotic Drug Law will greatly reduce the number of addicts who go about this state and attempt to procure morphine from one physician after another for the sole purpose of satisfying their craving for narcotics. The Medical Board wishes again to particularly caution the medical profession against furnishing or prescribing narcotics for these addicts. Most of them will not submit to a physical examination nor do they want to be hospitalized. The Medical Board feels that the imposition of a few more sentences like the one in this case, will go a long way toward solving this problem. There can be no question but what these persons need medical treatment and hospitalization, but it goes without saying that their addiction cannot be removed in a period of a few months.

ORALSULIN

No oral insulin preparation has been accepted by the Council on Pharmacy and Chemistry. Over eleven years ago *The Journal,* in discussing "Enterocap Oralsulin" (Dec. 4, 1926, p. 1935), pointed out the lack of evidence for the efficiency of orally administered preparations of insulin and pancreas. No new evidence has been found to necessitate a revision of the statement published at that time. Recently the federal authorities charged with the enforcement of the Food and Drug Act seized a shipment of Enterocap Oralsulin and declared the product adulterated and misbranded. According to the government report, examination showed that the preparation contained no insulin and that the labeling bore false and fraudulent representations regarding the curative or therapeutic effects of the product (Notice of Judgment 27373). No products of Lafayette Pharmacal, Inc., stand accepted by the Council on Pharmacy and Chemistry. (J.A.M.A., May 28, 1938, p. 1858.)

OF GENERAL INTEREST

Dr. Floyd F. Clark, who has practiced in Duluth for more than thirty years, is a candidate for county coroner.

* * *

Dr. Hamilton Montgomery of Rochester recently addressed the Chicago Dermatological Society, of which he is president.

* * *

Dr. C. B. Wright of Minneapolis was reëlected a member of the Board of Trustees of the American Medical Association at the convention in San Francisco.

* * *

Dr. Jere W. Annis (Minn. '35), for the past three years a fellow in medicine at the Mayo Foundation, has located in Lakeland, Florida, where he will practice internal medicine.

* * *

Dr. William Musfelt of San Diego, California, has finished his graduate course at the U. S. Veterans facility of Minneapolis, and has been transferred to Camp Custer, Mich.

* * *

Dr. W. R. Kostick is now located in Fertile, with offices over the Fox Theatre. Dr. and Mrs. Kostick and baby daughter moved to Fertile from Robbinsdale, where the doctor had formerly practiced.

* * *

The bill which was pending before Congress providing for a new building for the Army Medical Library and Museum, of which editorial mention was made in the June number of Minnesota Medicine, was passed by Congress and the building provided for.

* * *

Dr. L. J. Leonard of Minneapolis, who recently filed as candidate for Hennepin County coroner, is one of the few men in the United States who is both a practicing attorney and physician, and the only one in the Northwest licensed to practice both medicine and law.

* * *

Dr. Robert Leighton, Jr., a graduate of the University of Minnesota, who served his interneship at Minneapolis General Hospital, on June 1 became associated in the practice of medicine and surgery with Dr. W. F. Cantwell of International Falls.

* * *

Dr. G. B. Cross and family have left Hills, where they have lived for seven years, and moved to Lakeville, where Dr. Cross will be affiliated with the hospital at Farmington, as well as taking care of the practice at Lakeville.

* * *

The marriage of Miss Rose Jessen of Saint Paul and Dr. Maurice C. Rousseau, son of Dr. and Mrs. Victor Rousseau of Maple Lake, took place on June 18. Dr. Rousseau is a graduate of the medical school of the University of Minnesota, and his bride is a graduate of the St. Joseph's School of Nursing.

Dr. R. A. Murray of Hibbing took over the practice of Dr. S. Z. Kerlan of Aitkin, the latter part of June. Dr. Murray has been associated with Dr. J. R. Manley of Duluth. Dr. and Mrs. Kerlan have left for California, where their son. Robert, will enter the University of California this fall.

* * *

Dr. F. J. Hirschboeck of Duluth, program chairman· Dr. Charles N. Hensel of Saint Paul, president; and Dr. M. H. Hoffman of Saint Paul, secretary-treasurer, were in charge of the program for the semi-annual meeting of the Minnesota Society of Internal Medicine held in Duluth on June 4. The meeting was attended by fifty medical men from all sections of the state.

* * *

Dr. Archie Nissen has been appointed Assistant Superintendent of the St. Peter Hospital, succeeding Dr. Ralph Rossen, who was recently named Superintendent of the Hastings State Hospital. Dr. Nissen is a graduate of the University of Minnesota School of Medicine, where he specialized in psychiatry, and later did graduate work. He has served for the past two years on the medical staff of the St. Peter Hospital.

* * *

Among other similar courses offered at various centers in the state during May, an all-day postgraduate course in the care of mothers and babies was given at Worthington. The course was arranged under the auspices of the State Department of Health, the University of Minnesota, and the Minnesota State Medical Association with Dr. A. J. Chesley, secretary of the department of health, and Dr. E. C. Hartley, director of the division of child hygiene, in charge. The faculty for the course included Dr. Rae T. LaVake, Dr. Samuel B. Solhaug, Dr. Edgar J. Huenekens and Dr. Irvine McQuarrie of Minneapolis. Such gatherings are financed by the social security funds granted for the purpose to the state department of health.

* * *

Attendants at the American Medical Association convention in San Francisco in June were Drs. W. F. Braasch, H. H. Bowing, J. F. Wier, B. E. Hempstead and F. J. Heck, C. F. Dixon, and Waltman Walters, all of Rochester, Minnesota.

Dr. Braasch is a member of the House of Delegates of the Association and took part in the program of the American Board of Urology. Dr. Bowing addressed the meeting of the Los Angeles Cancer Society, and spoke both before the meeting of the A.M.A. and the meeting of the American Radium Society. Dr. Heck spoke before the A.M.A. meeting and also at the meeting of the American Society of Clinical Pathologists. After speaking before the section on surgery of the A.M.A., Dr. Walters went on to Vancouver, B. C., to deliver a series of talks at the summer school of the Vancouver Medical Association.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR JULY

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 9:45 o'clock every Saturday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

July 2—Artificial Respiration.
July 9—Body Temperature Regulations.
July 16—Summer Complaint.
July 23—Art of Relaxation.
July 30—Teething.

AMERICAN CONGRESS OF PHYSICAL THERAPY

An intensive course in physical therapy will be held September 7-10, 1938, at the Palmer House, Chicago, just preceding the 17th annual convention of the Congress of Physical Therapy. The course will consist of lectures, conferences, clinics and demonstrations arranged primarily for physicians but open to a limited number of technicians properly sponsored. Applications should be sent to the Congress headquarters, 30 N. Michigan Avenue, Chicago. Upon acceptance, a fee of $25.00 will be required.

EAST CENTRAL MINNESOTA SOCIETY

The East Central Minnesota Medical Society met at Pokegama Sanatorium at Pine City on May 27, 1938. Dr. Walter P. Gardner, Anoka, and Dr. Edward J. Coffman, Anoka, were accepted as transfers into this society.

Dinner was served and in the evening a scientific program was presented by guest speakers. Dr. O. H. Wangensteen discussed thoracic surgery and a discussion of his subject was presented by Dr. D. Greth Gardiner. Dr. R. E. Hultkrans spoke on "Chronic Low Back Pain" and Dr. Stewart Shimonek followed with a short discussion of this subject.

SCOTT-CARVER SOCIETY

At the annual meeting of the Scott-Carver Medical Society held at Mudbaden, June 14, Dr. C. A. Stewart, of Minneapolis, spoke on "Dietary and Nutritional Problems in Pediatrics."

The following officers were elected for the coming year:

President—Dr. Earl Crow, Arlington
Vice President—Dr. Harold Havel, Jordan
Secretary-Treasurer—Dr. B. F. Pearson, Shakopee
Delegate—Dr. C. F. Cervenka, New Prague
Alternate—Dr. J. C. Klein, Shakopee
Censor—Dr. Alvin Westerman, Montgomery

Meeting of April 13, 1938

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, April 13, 1938. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 by the president, Dr. R. T. LaVake.

There were fifty-seven members and two guests present.

Minutes of the March meeting were read and approved.

Dr. H. E. Hullsiek read the Necrology Committee's Memorial to Dr. John T. Rogers, and a motion was carried that it be spread upon the records of the Academy and a copy sent to the family.

JOHN THOMAS ROGERS*

1867-1938

The Civil War was in every sense a social revolution. Through the sweep of the conflict the planting aristocracy of the South was as completely ruined as were the clergy and the nobility during the French Revolution. The very economic foundations of the planting system, including slavery itself, were destroyed.

Even before the unrest associated with the freeing of the slaves, the South had at no time a static population, and to the migrating groups Kentucky had ever added her share. Beginning with the settlement by Daniel Boone in 1775, through its admission to statehood in 1792, and up to 1890, it had been first an outpost, and finally a point of departure for those seeking fortune elsewhere. By 1880 it was no longer frontier, but a great commonwealth with thousands of prosperous citizens. Still the blue-grass state annually sent out many who could not resist the beckoning will-o-the-wisp of fortune. The last great migration occurred between 1880 and 1890. This exodus was the result of the moral and material disintegration incident to the great war. In this decade 50,000 souls left the state which, during its history, furnished the rest of the Union with some twenty governors, many senators, attorney-generals, justices, and other high officials. It was at this time that the Rogers family left Kentucky for Minnesota.

William Edward Rogers was born at Cane Ridge, Bourbon County, Kentucky, on August 12, 1835. On June 10, 1857, he married Margaret Vernon, descendant of Jacob Spears, revolutionary soldier. The fifth of their eight children was John Thomas Rogers, born July 18, 1867, at Versailles, Kentucky.

There is nothing to indicate that John Rogers' childhood was in any way different from that of any son of a comfortably landed proprietor of the South. However, before he was far on his way to manhood, the aftermath of the great civil strife descended with a vengeance and, like so many others, William Rogers sought fortune elsewhere. It is not strange that in 1886 he chose Minnesota.

St. Paul was in its first exuberant flush of youth. The population was 110,000; it claimed 864 manufacturing establishments, while 18,000 persons and 142 trains passed through the union station daily. The Robert Street bridge and that to Dayton's Bluff were being built; 3,573 buildings of various types had been completed that year; and the city was served by thirty-five newspapers and periodicals. As a further mark of progress, it was noted that already some of the horse-cars had been powered with cables.

The Rogers settled in St. Paul after a brief sojourn in the Dakotas. Young John was left in Louisville to complete his studies at Transylvania University, after which he joined them. The first note of him in this hustling and rather awe-inspiring city of French, Germans, and Irish from down river, is a listing in the St. Paul directory for 1887. Rogers, John—clerk for W. E. Rogers, real estate, 42 Globe Building—boards with W. E. Rogers, Chatsworth & Owasco.* How long he was employed by his father is not definitely known, and for some time he clerked in a haberdashery on Robert Street. Both of these positions were temporary and it apparently was not until he met Dr. Charles A. Wheaton that plans for his future were crystallized. Neither is it known in what manner he met Dr. Wheaton, but it probably was as a patient since he was sent to Brainerd at the instigation of Dr. Wheaton, with a note to a friend of the doctor's, remaining in the north woods six weeks. It might easily have been otherwise, since his father's office and the doctor's were but a block apart.

In 1888 he is living with his family in St. Anthony Park, and is a student with the firm of Wheaton and MacLaren. Dr. Wheaton at this time lived at 351 Washington Avenue, facing Rice Park, some three blocks from his office. Coming to St. Paul in 1877, he was well established in practice and was one of the northwest's surgical leaders. Young John helped about the office, read in the doctor's extensive library, and made himself generally useful. He assisted at operations, slept in the office and, in the absence of telephones, answered the night-bell, notifying Dr. Wheaton and driving him on calls.

In 1881 the St. Paul Medical College had taken into its faculty certain Minneapolis men, had moved to Minneapolis, and became the Minnesota College Hospital. In 1885 the St. Paul members resigned and again started the St. Paul Medical School, while the Minnesota College Hospital reorganized and became the Minnesota Hospital College. In 1888 the St. Paul Medical School and the Minneapolis institution surrendered their charters and became the College of Medicine and Surgery of the University of Minnesota,

*Memorial to Dr. John T. Rogers, read at the regular meeting of the Minnesota Academy of Medicine, on April 13, 1938

*Now Fairmount Avenue.

with a faculty of twenty-nine and Perry Millard as dean. The course of lectures consisted of three years of six months each, and it was here that John Rogers began his medical education in the fall of 1888. Living in St. Anthony Park, he took the Great Northern train at Merriam Park each morning and rode to the 10th street bridge. Here he got off and crossed the river to the medical school which was on 6th street, across the street from the old St. Barnabas' hospital.

Now for the first time were felt the tremors of the impending social and economic upheavals that were to mark the end of an epoch, that of the end of the period of free land—the last of the frontier. The post-war deflation had set in and the Rogers family had not been long enough in the new surroundings to have become well-established in business. John's father and brother, Nat, were in the stock business at South St. Paul, but with little surplus money left for medical studies. His arrangement with Dr. Wheaton not only was an opportunity to observe the practice of medicine and surgery first-hand, but was important from an economic standpoint as well. The financial status of the young aristocrat from the south was at times a sore burden.

One of the many stories he told to the writer dealt with the time when, because of well-worn shoes, he found himself wellnigh walking on the ground. His chief, affluent and a smart dresser, had noted this and caused a pair to be made, ostensibly for himself, but actually to John's measure. He brought them to the youth apologetically, saying that they did not fit him, and wondered if the young man might wear them, since it seemed a shame to allow them to be wasted. To quote Dr. Rogers, "Doctor, I was a proud young fool, I was extremely humiliated. That night when I walked across the bridge on the way to dissect I dropped the shoes into the river. I borrowed two dollars from a classmate and bought a pair of very fine shoes with paper soles." He told Dr. Wheaton the others had been stolen. I have heard Dr. Rogers repeat this story many times, with considerable amusement. It is an evidence of the fierce pride which, tempered by experience and maturity, was so great an asset in later years, and which so often enabled him to hold fast to what he felt was right.

Assisting at operations both in and out of the city —these were the days of weekend excursions to smaller cities with hospital facilities, and included turkey-shoots, banquets, poker-games, and Sunday morning surgical field-days—answering the office night-bell, driving Dr. Wheaton, dissecting evenings, spending the summer of the final year at the City Hospital, thus went the three years of from 1888 to 1891.

In 1891 President Harrison's difficulties with restless labor were beginning. The populist party was organized, great talk went on of gold and silver, the slogan "16 to 1" was mouthed about, falling wheat prices brought ruin of thousands, and on the streets of Chicago a curious crowd watched a vehicle which rolled along with no horse attached to it. In the realm of medicine, Witzel was performing his first gastrostomy, Quincke introduced spinal puncture, Bier brought out his hyperemia, a general aseptic ritual for surgery was standardized, and for the first time Halsted announced the use of rubber gloves. With this year came the end of John Rogers' first struggle for a foothold in the practice of medicine. His hardest days were behind him. Licensed to practice on April 10, 1891, and graduated in June of the same year, he is now a full-fledged physician associated with two of the best known men in the city, Dr. Charles Wheaton and Dr. Archibald MacLaren. He has left the family home, probably to be nearer his work, and is living at the Seville Flats.

Those who know him are acquainted with his meticulous methods in the matter of records and correspondence. It is questionable whether John Rogers ever ended a day's work without having completed his records and attended to his correspondence. Thus it is not surprising to find in a small pocket diary (an advertisement by the Maltine Company), careful notes of his first patients. He graduated in June, 1891, and what is probably the record of his first private patient appears on the page for June 12th, as follows: Wm. Swab—bartender—incised wound of forearm made by dirty hatchet—treatment: wound scrubbed with 1/2000 bichloride—iodoform dusted on—wound sutured with catgut—no inflammation.

On July 16th occurs the following: Dutchman—porter in saloon—got in row with waitress who stabbed him in buttock with butcher-knife. Wound three inches deep, very painful, bleeding profusely. Treatment: irrigation with 1/1000 bichloride, one silkworm suture, iodoform gauze. Union by first intention.

Apparently his first operation was a tonsillectomy. On September 20th this appears: Morris J.—Tonsillectomy. Enlarged and frequently inflamed tonsils—both removed under cocaine—no pain—little hemorrhage—no attack several months afterwards. On January 5, 1892, a cervical repair, and in February a breast abscess. In April a fractured clavicle and in June a mastoid abscess, described as follows: Baby T., 6 months old. History unsatisfactory. Had been scarlet fever in home but baby had not taken it. Did well for two weeks when it began to bleed after a dressing. Local doctor called but it didn't succeed with acid—I saw child 48 hours afterward almost in collapse—still bleeding—applied compress—administered whiskey—hot applications to body—recovered.

And so the record goes, with careful notes, comments, his own explanations of failure to get desired results—on through 1892—an abscess of the femur, another mastoid, in October of that year the first of a remarkable—for that time—series of ectopic pregnancies, described with great detail and occupying two pages of small script, a repair of a cervix and perineum. On February 29th of this year, John Rogers joined the Ramsey County Medical Society.

At the age of 26 years, on April 4, 1894, he read his inaugural thesis before the Minnesota Academy of Medicine, entitled, "The Use of Wet Dressings and Poultices in Surgery." In this paper he cites his success with 1/3000 hot bichloride of mercury solution used as a wet dressing, as a substitute for the still-popular flaxseed poultice, which he condemns. He

states that a recent communication from one of the men at Johns Hopkins says that flaxseed poultices are still used in that institution in cases of stitch abscess. He ends by saying, "I believe the day is not far distant when adequate incisions will be small ones, large drainage tubes will be entirely dispensed with, and irrigations unnecessary." A bold statement for 1894!

By this time his case-book includes such operations as excision of the superior maxilla, extra-uterine gestation, repair of crushed foot, mastoid abscess, suture of tendons, amputation of leg, varicocele, pyosalpinx, curettage, appendicitis, hemorrhoids, pelvic abscess, varicose veins, hysterectomies, anal fistula, Dupuytran's contraction, compound fractures, hernia, amputation at the thigh, osteomyelitis, and others. A widely varied surgical practice for a young man four years after graduation.

In June, 1895, he was appointed Clinical Instructor in Diseases of Children at the University of Minnesota. On June 20th of that year he read before the Gynecological Section of the Minnesota State Medical Society the first of his papers on ectopic gestation, with a report of sixteen surgically-treated cases.

Considering that it was but six years since Tait had published his work on extra-uterine gestation, it is again an evidence of the young doctor's progressive spirit when he says he believes that this condition "could and should be diagnosed before rupture in a large majority of cases." He states that if the operation be in the hands of experts and the patient operated upon before rupture, the mortality should not be greater than 2 per cent. This number of cases was unusual for the time, and called forth a rebuke from a surgeon in an eastern clinic attended by Dr. Rogers. The young surgeon had taken part in the discussion following an operation for ectopic pregnancy, mentioning his experience and that of his colleagues in St. Paul. The eastern surgeon apparently felt that the young man from the raw middlewest was overstepping the bounds and remarked witheringly that if these doctors had sixteen such cases there must be very uncommon women in St. Paul. Dr. Rogers had the better of it. He took great glee in his reply, which was to the effect that the women in St. Paul were in no way unusual, but it was possible that the doctors were.

In 1897 he published a paper on the operative treatment of tumors of the upper jaw, and in May of that year was appointed Clinical Instructor in Surgery at the University of Minnesota. It was also in this year that he and Dr. A. B. Stewart of Owatonna were sent as delegates to the meeting of the American Medical Association in Philadelphia, one being certified to attend the International Medical Congress in Moscow. They left St. Paul in May, sailed on the City of Rome, arriving in Edinburgh on June 16th, after two or three days in Glasgow.

Here they took courses in practical pathology, morbid anatomy with Alexander Bruce, and had the run of the Surgeon's hall and the Royal Infirmary. In July they left Edinburgh on bicycles for Vienna by way of Dublin, London, Paris, Lausanne, Berlin and Prague, arriving after a six-week's trip. In Vienna they settled down for several months of study. They took courses in pathology, special dissection, general medicine, gynecology, and a course in blood disease with technic of staining specimens. Dr. Stewart says in a recent letter, "John was a diligent student and a delightful traveling companion. I learned much with him and from him."

Changes have occurred in the firm in the past three years. In 1897 it became Wheaton, Wheaton and Dennis, John Rogers having left January 1, 1897, to practice alone at 145 Lowry Building. Bob Wheaton having died suddenly in 1898, the firm became Wheaton, Rogers and Dennis.

In June of that year Dr. Rogers presented before the State Society a paper on contused wounds of the abdomen and their surgical treatment. Here he makes a plea for early recognition of intra-abdominal injuries resulting from contusions, emphasizing the point that this condition had not been adequately dealt with in the literature, which he says is "incomplete and unsatisfactory in its treatment of this condition." He hopes to create more interest in this type of serious injury, leading to further study and more frequent reports of cases, since, as he says, ". . . the advances in modern surgery have made it possible to explore the abdomen with impunity and almost with safety." In the year 1901 Dr. Rogers was elected President of the Minnesota Academy of Medicine.

It is now 1902. The Spanish-American war has come and gone with its scandals and profiteering, the beginning of the Roosevelt ascendency, and the beginning and end of the United States' short-lived fervor for foreign expansion. John Rogers is now associated with Dr. Wheaton, the firm name being Wheaton and Rogers. Reading papers at meetings, giving talks in and out of the city, participating in both development of the education and economic side of medicine as well as the purely scientific, he was adding rapidly, through ability as well as personality, to what had already become a large following. Two more papers on ectopic gestation, one reporting twenty cases, both plead for earlier diagnosis and proper treatment, showed that when John Rogers believed himself to be right the chips might fall where they would. He handled without gloves those who, he felt, through failure to grow with medical science were failing in their duty. A paper written on cancer of the breast, one read at the Academy on surgical cases, immobilization of the lower jaw, and one on tumors of the upper jaw and their operative treatment had appeared. The last mentioned was written six years after graduation, and reported several personal cases.

In 1903 the firm became Wheaton, Rogers and Gilfillan, with offices at 170 Lowry Arcade, and in 1905 Wheaton, Rogers and Colvin. During these years we find Dr. Rogers appearing before assemblies with papers on such subjects as tuberculosis of the kidney, differential diagnosis of gallstones, surgery of the bileducts, surgical treatment of the gallbladder, gunshot injuries of the brain, gastric ulcer, intussusception. One article, entitled, "The Health Instinct," appeared in *Popular Science Monthly.*

During this, the gilded age in American scientific,

economic and social development, with revolution occurring with disturbing frequency in all branches of thought, John Rogers was not only an interested onlooker but an enthusiastic participant. The progress in science, the frequency of innovation in medical and surgical circles, the swiftness with which yesterday's beliefs were cast aside for today's, were staggering, and taxed one to keep abreast. Dr. Rogers' writings through these years show not only an attempt to do so, but a reasonable success.

The volume of surgery done in those days by any one or a group of surgeons is worth noting. At the time under discussion more of the work of this group was done at St. Luke's Hospital than at other institutions. We know that it was not all confined to one institution, and also that there were the above-mentioned weekend excursions to smaller towns, with operations on Sundays. Yet, in one of these years, over a hundred patients were operated upon by this firm at St. Joseph's Hospital. During the years from 1880 to the early 1900's much of the surgery from Minnesota to the West coast was done in the Twin Cities, as is shown in the variety of the cases. No one city could have furnished certain rather uncommon types of cases in such numbers as the records show.

Dr. Wheaton, having retired by 1912, the firm became Rogers and Colvin. At this time the City Hospital staff was reorganized with Dr. Rogers as chief. When the American College of Surgeons was founded in 1913 he was one of the founders. In January of this year he became Assistant Professor of Surgery at the University of Minnesota; and, in 1914, he married Lillian Hallam Cooley, making a European trip as his honeymoon. In 1914 he was president of the Minnesota State Medical Association. In his presidential address he dealt with such subjects as the liquor question, medical licensure, legislation, medical defense and expert testimony, ending with a discussion of the then burning question of medical education and the Medical School. Here again, his remarks show a refusal to compromise with what he believed to be wrong. In 1915 the Rogers-Colvin partnership was dissolved and Harry Zimmermann entered Dr. Rogers' office as surgical assistant, the firm becoming Rogers and Zimmermann. In 1916 he was made Associate Professor of Surgery.

Through all these years, the seed of an idea was growing in the mind of one of St. Paul's pioneer business men, the development of which was to be of untold benefit to those less favored than himself. This man was Charles T. Miller, erstwhile clerk for J. J. Hill and one-time partner of W. F. Davidson in the steamboat business. It had long been Mr. Miller's wish that a hospital be built and named for the one whom he held in such high regard and esteem—John Rogers. Dr. Rogers refused to accede to this wish, insisting that the hospital be named for its donor. Mr. Miller died without having carried out his plan, but it was periodically discussed by his widow and Dr. Rogers. When she died several years later, she made a bequest of $1,400,000 for the building and equipping of a hospital, a board of trustees being named at the same time. The sole stipulation was that there were to be fifty free beds, with no distinction as to color, race or creed. Dr. Rogers was named chairman of the board.

In 1917 a site was purchased and plans drawn for a hospital of 150 beds. According to the estimates made at the time, this could be built for $400,000, leaving $1,000,000 for a maintenance endowment. In the months intervening between the planning and the actual time of construction, the war had forced building costs so high that it was seen that the building as planned could not be erected and equipped and the endowment left intact. It was thus decided to postpone the building to a more favorable time, and allow the fund to grow.

Meanwhile, we had entered the war. In the summer of 1918, Surgeon General Gorgas arrived in St. Paul on a tour of the country in search of hospital facilities for American soldiers soon to return from France. After examining the Miller Hospital plans he advised the Board that if they would increase the number of beds to 250 and complete the structure, the government would take it over for a term of years. Patriotism and expediency finally caused the Board to accept this offer. The contract was let, construction rushed, and by the fall of 1918 the building was well under way.

In November 1918 came the armistice. With neither warning nor explanation, a telegram arrived unqualifiedly cancelling the afore-mentioned offer. The Board now found itself in a difficult position. It was obvious that the increased size of the hospital, together with still high construction costs, would leave little of the endowment fund for maintenance. After months of effort and after finally believing their troubles to be over, the Board suddenly found themselves, through a combination of circumstances, in a worse situation than before. Insurance, fire-protection, interest, heating, and other costs were mounting alarmingly. Permission was finally obtained from the court to use the endowment fund for the completion of the building, which was finished in November, 1920.

In order that the hospital might open, it was necessary to borrow, for the purpose of equipment, approximately $150,000. This was accordingly done, and the hospital opened its doors to the first patient on December 1, 1920.

The Charles T. Miller Hospital was not named for John Rogers, but those of us who know him realize that it is as much a monument to the dogged persistence, untiring effort, and almost fanatic devotion to an ideal, of one who was carrying out the wishes of a friend, as though the institution were named for him. It is safe to say that the only time in his life that John Rogers incurred the displeasure of anyone, was during the planning and building of this hospital, and then only because he held out against any and all influences which in his mind might in any way obstruct the furtherance of a great project. Fortunately, it was but a short time before all ill-feeling toward Dr. Rogers and the Miller Hospital was dissipated. From the time of its inception to the time of his death, John Rogers made the Miller Hospital his one thought. His com-

plete success is shown, I believe, in the fact that in no year since its opening has the hospital cared for less than 1,000 free patients, reaching a high mark of 1,775 in 1937.

From the several months of conferences with his confrères who were eventually to be financially responsible for the hospital's opening, came the idea of an association to practice medicine in a group. From this grew the Miller Hospital Clinic which was organized in 1922 and continued for the practice of medicine and the training of younger men until it was dissolved in 1934.

In looking back over my years of association with Dr. Rogers, I should say there were, of his many good qualities, three that were outstanding. The one obvious to all was, of course, his great personal charm, which instilled in those meeting him for the first time a feeling of respect and trust. The second, and not so obvious, was his tremendous capacity for work, with apparently little effort. John Rogers had a powerful physique, one which most of his life enabled him to outdo physically not only his contemporaries, but often younger men. As a woodsman he was indefatigable. His hunting partners for thirty years will testify to this. It was well known to his associates that he could do twice as much work as most, see an astonishing number of patients, and at the same time give the impression of being quite at leisure. At any time he was ready and willing to help with another's problem, be he intern, nurse, doctor, or friend—for John Rogers was interested in people. And, lastly, he was honest.

Had Dr. Rogers neither prescription-pad nor scalpel, I believe he could still have accomplished more for ailing humanity than many physicians. He had the very rare and precious quality which enabled him to do for a patient the one thing that a patient wants done when he consults a doctor—that of being made to feel better. Meeting and talking to John Rogers had that effect. Samuel Bard said one hundred years ago—"The physician who confines his attention to the body knows not the extent of his art. If he knows not how to soothe the irritation of a troubled and enfeebled mind, to calm the fretfulness of impatience, to rouse the courage of the timid, and even to quiet the compunction of an over-tender conscience, it will very much confine the efficacy of his prescriptions; and these he cannot do, without he gain the confidence, esteem, and even the love of his patients." I know of no one having incorporated in his makeup to a greater extent these qualities than had John Rogers.

The last three years of his life he was far from well. Following the death of his wife he was beset with evils of body as well as spirit. He had the misfortune to break his leg and was confined for some time. A year ago he had a rather severe gastric hemorrhage, which he feared might be of malignant origin, but which was later proven not to be. He refused to cease entirely seeing patients although he spent increasingly more time away from his office. But a year ago he made a world tour with his daughter. He had been about as usual and the news of his sudden death from heart failure came as a surprise on January 2, 1938.

In the year 1755 a little girl walked with her mother along a London street. Jostled to one side and being too tiny to see, she complained to her mother. The occasion was the passing of Samuel Johnson and some friends along the narrow sidewalks of Temple Bar. "Hush, child," said the mother to the little one, "a great man has passed by."

Upon ballot the following men were elected as candidates for membership in the Academy:

Dr. Albert Snell, Rochester, Associate Member.
Dr. Gilbert Thomas, Minneapolis, Active Member.

It was decided to have a non-scientific summer meeting at the country home of Dr. Archa Wilcox, and that Dr. Wilcox and a selected committee should decide just when the meeting is to be held.

The scientific program followed.

SPINA BIFIDA CYSTICA OF THE PELVIS

Diagnosis and Surgical Treatment

ALFRED W. ADSON, M.D.
Rochester, Minnesota

(See page 468, this issue)

Discussion

DR. F. C. RODDA, Minneapolis: We have had the following experience. Operation for the repair of spina bifida in infants two to four months of age, in which the hydrocephalus seemed to be quiescent, has been followed by a very sharp and rapid increase in the size of the head. On the other hand, where the operation has been delayed until the child has reached the age of ten or twelve months, we have not had this difficulty. It would appear as though the sac acted as a sort of safety valve in the early months of life. I should like to ask Dr. Adson if that is a factor in his selection of a nine months' age limit.

DR. F. R. WRIGHT, Minneapolis: What is the general outlook as to prognosis of these cases? Do they recover and make physiologically healthy individuals, or do they recover just sufficiently to be taken care of by somebody else?

DR. ARNOLD SCHWYZER, Saint Paul: I rise to discuss this paper because Dr. Wright has asked the question as to whether these patients are any good afterward. I saw, a few weeks ago, a man who came in with his mother who was sick. She said, "You know, I think some twenty-three or twenty-four years ago you operated on our baby. This fellow here is that baby." In this case there was a large meningocele in the upper cervical region, and this young man was a regular giant in size and strength. His neck showed a somewhat irregular scar. The worst forms are the myeloceles where the whole medullary canal is open. Inside of the edge of skin there is the zona serosa and, in the center a granular looking surface, the medullary tissue. In the median line above and below, one can see a little dimple which represents the entrance to the medullary canal. I have operated on two such cases, but there is not great opportunity to do much for the condition. Both babies lived, but the paralysis of the lower extremities persisted. The cord lies open in the center. For a couple of days before operation we try to get the area clean by using saline irrigations and a salicylic acid solution. Then the myelocele is closed. Both of these patients were paralyzed and stayed paralyzed, so far as we know, except that one of them, the child of a doctor, has shown considerable im-

provement in the feet. They are not entirely paralyzed.

(Note: Inquiry after the meeting from the father of this child with myelocele and an open central medullary canal reveals that the child can move the thighs and stretch and bend the knees. The feet are being treated orthopedically, and there is a grave sensory deficiency.)

Of tumors of the anterior area of the sacrum, Dr. Adson mentioned chordomas and teratomas. The first surgical case I had in my practice was a man sent to me by another doctor. The lesion was congenital. At birth it had apparently fluctuated, was incised by the attending physician, and never healed. The man was a poor farmer's helper and had always slept in the hay out in the barn because there was such a terrific odor about him. He was 18 years old when he came to see me. His was a presacral teratoma, between the sacrum and rectum.

A case of chordoma which I had in this area was brought before this Academy some time ago. [Meeting of October 7, 1936. Published in MINNESOTA MEDICINE, 20:15, (January) 1937.]

I should like to ask Dr. Adson if the sac in his case was injected with an obliterating fluid like alcohol.

DR. F. E. B. FOLEY, Saint Paul: This is one of the most interesting papers I have heard presented before the Academy. Dr. Adson has presented the subject of meningocele in a way most instructive and helpful to those concerned with the clinical surgical problem. My own interest is more in the physiology and pathologic physiology of the condition. This interest carries over from experimental work on the physiology of the cerebrospinal fluid done in association with Dr. Harvey Cushing in 1920. I would like to ask some questions bearing on this phase of the matter.

Is not the hydrocephalus developed following removal of a large meningocele always of the communicating type? Obstructive hydrocephalus due to occlusion of the aqueduct or the foramina entering the subarachnoid space should exist independently of the meningocele and not be influenced by its removal. Does occurrence of a communicating hydrocephalus in response to removing a meningocele indicate that the lining of the cyst had been a pathway for absorption of fluid and had protected the individual from hydrocephalus? Is removal of this absorbing surface directly responsible for the hydrocephalus?

In commenting on hydrocephalus secondary to removal of a meningocele, Dr. Adson mentioned the theory of Morgagni. This theory presupposes that the choroid plexus behaves as a secreting gland and that the cerebrospinal fluid is a true secretion. The experiments which I devised and carried out in Dr. Cushing's laboratory disprove this. They showed conclusively that the choroid plexus is not a secreting gland and that the fluid is a product of purely physical factors—filtration, osmosis and diffusion. A mixture of solutions of iron ammonium citrate and potassium ferrocyanid was supplied to the subarachnoid space from a manometer. The animal was then given a hypertonic salt solution intravenously. Incident to the increased absorption of cerebrospinal fluid and fall of fluid pressure thus induced, a considerable volume of the citrate-ferrocyanid mixture was displaced from the manometer into the subarachnoid space. On perfusing the animal with formalin containing hydrochloric acid, insoluble granules of Prussian Blue were precipitated from the mixture at the sites to which it had reached. It was found that a reversal of flow in the aqueduct had occurred and that fluid now moved from the subarachnoid space up the aqueduct into the ventricles. There was a heavy deposit of Prussian Blue over the ependymal cells of the choroid, between these cells and in the choroidal vessels. The experiment proved that the increased osmotic value of the blood had reversed the flow of fluid through the choroid plexus which now ceased production of fluid and became a pathway of fluid absorption. Some years later these experiments were repeated and verified by Freemont-Smith. They show conclusively that the fluid is a product of purely physical factors and is not a true secretion. May it not be possible to put this fact to good purpose in the surgical treatment of meningocele?

DR. ADSON, in closing: In reply to Dr. Rodda's question as to whether or not a balance develops between the secretion and absorption of cerebrospinal fluid in communicating hydrocephalus, I wish to say that it is my opinion that a balance does develop when there is not too large a difference between the factors involved; that is, when the absorption mechanism is capable of absorbing most of the fluid secreted.

In reply to Dr. Wright's questions as to whether or not surgery is worth while, I wish to emphasize the point that I made in the paper. This was that the surgical treatment of spina bifida cystica is not indicated in the presence of an extensive hydrocephalus, nor is it indicated in the presence of a syringomyelocele when extensive paralysis is manifest. In the remaining group of cases it is definitely indicated and worth while.

I doubt if surgery is of material value in the treatment of spina bifida occulta. Occasionally, adhesions may be relieved and a fatty tumor found which, when removed, may give some relief; more often than not, however, nothing can be done from the surgical point of view. The symptoms most usually are the result of a myelodysplasia.

In reply to Dr. Foley's question as to whether or not the choroid plexus is a secreting gland, I wish to state that I am familiar with his experimental work and agree with him that the cerebrospinal fluid is not a secretory product of the choroid plexus but is a transudate as a result of various physical phenomena. However, the point that I wished to make was that the cerebrospinal fluid was eliminated by the choroid plexus into the lateral ventricles and had to find its way into the subarachnoid spaces. Otherwise a hydrocephalus would result.

CASE REPORT

FREDERIC E. B. FOLEY, M.D., and
JOHN E. DEES, M.D. (by invitation)
Saint Paul

The case to be reported is that of a married woman, aged fifty-five (Ancker Hospital record No. A6941). The patient had been treated for three years in the cardiac clinic of the Ancker Hospital for auricular fibrillation. She was admitted to the hospital on January 8, 1938, complaining of severe pain in the left flank and back for the preceding thirty-six hours. The onset had been sudden. The pain was severe and constant, being localized in the left costo-vertebral region and flank. There was no downward radiation. On three occasions since the onset of the attack she had noted gross blood in the urine. There had been no other urinary symptoms, no chills or vomiting.

On admission significant findings on physical examination were a temperature of 100° F, marked obesity and extreme tenderness to palpation over the left flank and costo-vertebral region. No mass was palpable. There was a rapid auricular fibrillation with an apical heart rate of 160 per minute, the blood pressure being 120/90. Except for a few râles in the bases of the lungs, there were no signs of decompensation.

Laboratory examinations showed the hemoglobin to be 78 per cent, leukocyte count 25,800, sedimentation rate 55 mm./hour, urea nitrogen 28 mmg. per cent.

The urine showed an occasional leukocyte and granular cast, no erythrocytes, l-albumin, no sugar and it was sterile on culture.

On January 10 x-ray of the abdomen was negative for a rather large left renal shadow. Intravenous urography showed a well functioning, apparently normal right kidney with no excretion of dye from the left kidney in thirty minutes. Cystoscopy was then carried out. The bladder was negative. A No. 6 catheter was easily passed to the left kidney. There was no drainage of urine from the catheter but irrigation of the left renal pelvis with normal saline solution reproduced the patient's pain. The catheter was left in place for five hours at the end of which time it was removed as there had been no drainage of urine through it. Retrograde pyelography was not carried out at this time as the patient's temperature was 102° F.

The temperature subsided slowly from a maximum of 102 on January 10, reaching normal on January 18, the tenth day of hospitalization. Spontaneous pain in the kidney disappeared by the fifth day of hospitalization and tenderness to pressure by the seventh day.

On January 18 the left ureter was again catheterized. There was no drainage of urine nor could any be aspirated from the renal pelvis. The ureteral catheter was removed and a bulb catheter wedged into the left ureteral orifice. A pyelo-ureterogram was made after the injection of 11 c.c. of 20 per cent hippuran solution, which amount reproduced the patient's pain. The resulting picture showed an essentially normal, unobstructed ureter and kidney pelvis. A diagnosis of massive embolism of the left renal artery was made at this time.

Two days later cystoscopy was again carried out. Indigo-carmine appeared in good concentration in three minutes from the right ureter but none during ten minutes observation was seen to come from the left side. A No. 14 bulb catheter was wedged into the left intramural ureter and left in place for thirty-five minutes during which time there was no drainage of dye or urine through it.

The patient left the hospital on January 23. At this time there were no symptoms referable to the urinary tract. The urine contained many erythrocytes and leukocytes. The tachycardia had disappeared under digitalis.

The patient has been re-admitted for study on three occasions since discharge, two, three and four and one-half months respectively after the onset of her illness. Intravenous urography and cystoscopy after the injection of indigo-carmine intravenously as well as ureteral catheterizations have consistently showed an absence of excretion of dye or urine by the left kidney. Bulb pyelo-ureterograms have shown a progressive decrease in the capacity of the left renal pelvis and ureter from 11 c.c. on January 18 to 4 c.c. on May 16, The size of the pelvis and renal shadow have decreased markedly, the general configuration of the pelvis being preserved in miniature. There have been no urinary symptoms or evidence of other embolic episodes.

Cursory review of the literature in connection with this case report discloses publications on the subject beginning in 1856 when Traube first reported the condition. Schultz, five years previously, had ligated the artery in an experimental animal and observed atrophy of the kidney. Blessig, in 1859, in a similar experiment concluded that the renal artery was necessary, not only for the function, but for the nourishment of the kidney. He found that its ligation was followed in the first few days by venous engorgement and that this might cause actual hemorrhage if thrombosis of the vein also occurred. This latter observation is difficult or impossible to explain reasonably. With total occlusion of the artery, hematuria should be expected only in the presence of a patent vein. In such event venous pressure in the cava being higher than in the venules of the kidney, there should be engorgement of the kidney with diapedesis and blood in the urine the result. Why bleeding should occur in the presence of occlusion of both artery and vein is hard to understand and would seem to indicate fault in the experiment.

Buchwalden and Littin, in 1876, ligated the renal vein and found initial enlargement of the kidney with shrinkage of the kidney beginning by the sixth day and finally with establishment of collateral venous circulation through capsular renal vessels and lumbar veins with some preservation of function. This was corroborated in 1913 by Morrell and associates. These investigators found that following ligation of the artery rapid necrosis, atrophy and death of the kidney invariably resulted.

Westerborn, in 1937, reported careful observations and operation in a case very similar to the one here described. He also made some animal experiments. He found that one and one-third hours is the longest period of arterial occlusion that will be followed by total recovery of the kidney. He reports that occlusion of an hour and a half invariably results in impaired function. He concludes that embolectomy if done at all should be done in the first hour and certainly not later than two hours.

Eisendrath, in 1934, reviewed the reported cases of both arterial and venous occlusion—some forty cases in number, and concluded that of them only twenty-five were acceptable examples of the condition.

The numerous publications do not sharply distinguish between total occlusion of the main renal artery, multiple occlusions of its smaller branches and venous occlusion. For this reason it is difficult to know the exact character of the vascular occlusion or combination of occlusions that was responsible for the clinical findings in the reported cases.

Consideration of the reports of massive renal infarct makes it appear that the characteristic onset is one of sudden severe pain, usually localized to the kidney region although at times being epigastric. The pain is without remission or radiation and usually of such severity as not to be relieved by morphine. In the majority of cases gross hematuria occurrs. Apparently it may be present with primary arterial as well as primary venous occlusion.

The reports are agreed that there is exquisite tenderness of the affected kidney with or without spasm of the overlying muscles. Albuminuria is the most frequent laboratory finding occurring in roughly 60 per

cent of the cases referred to. It tends to decrease or disappear by the sixth day.

The papers to which we have had access disclose only three cases closely analogous to the one here reported—that is embolism or sudden arterial thrombosis with complete occlusion of the whole renal artery. None of these reported cases contains detailed information concerning frequently repeated observations following the event though in two cases subsequent cystoscopy and pyelography are reported with findings similar to ours. The case we have described appears to be the most complete and detailed observation of the condition as clinically encountered.

The meeting adjourned.

Meeting of May 11, 1938

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, May 11, 1938. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 by the president, Dr. R. T. LaVake.

There were forty-nine members and three guests present.

Minutes of the April meeting were read and approved.

The scientific program followed.

NON-TUBERCULOUS SPONTANEOUS PNEUMOTHORAX

E. V. Kenefick, M.D.
Saint Paul

Abstract

Spontaneous pneumothorax may be caused by tuberculosis, lung abscess, bronchiectasis, emphysema, empyema, carcinoma of the lung, lung cyst, and silicosis. Fracture of the ribs and puncture wounds of the chest were responsible for the first reported cases. Tuberculosis is the most common cause and is present in 70 to 80 per cent of all cases. Another small group without obvious cause are classed together because of a common symptomatology and course. Benign pneumothorax, idiopathic pneumothorax, and non-tuberculous pneumothorax are the various terms applied to this condition. It is this group I wish to discuss.

The various types of spontaneous pneumothorax encountered may be classified according to the degree to which the lung is collapsed. The collapse may be partial or complete, with or without mediastinal displacement. If the pressure continues to increase a tension, pneumothorax may develop. Recurrent attacks are common. Simultaneous bilateral pneumothorax may occur and is much more serious than the unilateral form. Hemopneumothorax is also a serious type, due to the presence of large amounts of blood in the pleural space.

The close relationship of pulmonary tuberculosis to spontaneous pneumothorax has been an accepted dictum for many years. Several reasons may be advanced to prove this is not true in all cases. Spontaneous pneumothorax occurs usually in the late stages of tuberculosis. If it does occur due to the rupture of a solitary focus in the pleura, a pleural effusion invariably results. In spontaneous pneumothorax, pleural effusion is not present and follow-up studies do not reveal the presence of pulmonary tuberculosis. Kjaergard has studied fifty-one cases, some of which were followed for as long as eighteen years, and found only one patient had developed active tuberculosis. Morriss studied twenty-six cases over a period of from three to eleven years, and found no tuberculosis. The more general employment of the tuberculin test and routine x-ray examination of the chest has demonstrated that an antecedent tuberculous infection is not necessary in the development of spontaneous pneumothorax.

The condition occurs most frequently in young males between twenty and thirty years of age. Physical effort or strain does not play any part. Ranking, Pitt, Hayoshii and Fisher have reported finding vesicles at the apices of the lung surrounded by areas of emphysema or retracted areas due to scar tissue. No evidence of tuberculosis was present in any of their autopsied cases, six in number. Fisher and Hayoshii ascribe the pneumothorax to the rupture of a vesicle, usually situated at the apex, which is surrounded by either scar tissue or emphysematous tissue, closed by a valve at the base. The valves develop from inflammatory processes with resulting scar tissue formation, producing a constriction of the lung tissue or bronchiole.

Case histories of seven patients with spontaneous pneumothorax were presented together with the results of tuberculin tests and x-ray studies of the chest. These studies failed to reveal evidences of tuberculosis in any of the patients. The follow-up period was five years in all cases. Mantoux tests were negative except for one patient with a plus reaction three years after the attack of pneumothorax. Fever was not present and there was no evidence of pleural effusion in any case. All patients completely recovered in from two to six weeks with simple bed rest and symptomatic care.

CONCLUSIONS

1. Non-tuberculous spontaneous pneumothorax occurs in healthy young adults without demonstrable cause and runs a benign afebrile course with complete recovery in a few weeks.

2. The condition is caused by the rupture of a pleural valve vesicle either emphysematous or scar tissue in nature.

3. Tuberculosis is not a factor in this type of spontaneous pneumothorax.

4. Roentgenology and tuberculin tests are extremely valuable aids in the diagnosis and treatment of this condition.

Discussion

Dr. E. V. Goltz, Saint Paul: I recently had an opportunity of observing just such a case as Dr. Kene-

fick reports, and his paper has been very interesting to me because of this recent experience, for his cases simulate mine very closely. It seems to me the interesting observation here is the etiologic factor. While it is true that some claim 80 per cent of their spontaneous pneumothorax cases to be tuberculous, I think this probably holds true more in hospitals and sanatoria. In private practice I think one can not claim so high a percentage. The problem is to prove that these young people who have these benign spontaneous pneumothoraces are not tuberculous. Dr. Kenefick has shown very definitely that his group is not tuberculous; and, if this can be proven, it is certainly very much worth while in the prognosis.

Dr. S. Marx White, Minneapolis: One patient of mine at the age of 32 first had a spontaneous pneumothorax in 1928. He had two subsequent recurrences, each after about a year's interval, and two of the three attacks were brought on apparently by riding horseback. At the time of the first attack minor symptoms of a chronic type of arthritis were present, and subsequently a moderately severe extensive Strümpel-Marie type of spinal arthritis has developed. The Mantoux reactions have all been negative, and repeated x-ray films, taken at the time and subsequently, to the present time have been negative to tuberculosis.

A fact of interest is that a paternal uncle had very marked and extensive cystic disease of the lung, found at autopsy. In the x-ray films of this patient, however, we have not been able on careful search to find anything indicative of cystic disease of the lung, even though this was searched for at the time of the attacks.

Dr. Max Hoffman, Saint Paul: In the last two years I have seen three cases of spontaneous pneumothorax. None of them showed much air in the chest and in all cases the symptoms were minimal. There was some pain in the chest underneath the clavicle on the affected side, but there was much less air than in the cases Dr. Kenefick reported tonight. That would make one feel that spontaneous pneumothorax of mild degree is fairly common. The pain may last for a day or two and the condition may heal quite quickly. Last year I read an article in which the author had injected 25 per cent glucose into the thoracic cavity for this condition. He felt it was very effective in preventing a return of spontaneous pneumothorax. I have not had a chance to use this treatment.

Dr. C. M. Carlaw, Minneapolis: I was very glad to hear Dr. Kenefick's paper. It has taken me back many years. About the year 1890 at the Montreal General Hospital, Dr. George Ross, then Professor of Clinical Medicine at McGill, in one of his clinical lectures to the class of which I was a member, explained and demonstrated to us the use of the "Coin Test" in the diagnosis of pneumothorax. The second year after I was graduated I came to Minneapolis. One night shortly after, I was called to see a young man who was suffering with severe chest pain. I could not at first arrive at any diagnosis. Suddenly, however, I remembered Dr. Ross' lecture on the "Coin Test," tried it, and there was a pneumothorax as plain as the nose on his face. I made some inquiry into his family history and found that his mother had died of consumption, also an uncle on his mother's side. The patient looked as though he might have it too. That man got well after about two weeks' rest in bed. He is now an officer in one of our Minneapolis banks, has reared two fine healthy children, and has just been blessed with a fine big grandson; and he (grandpa) still does not show any signs of tuberculosis.

Dr. Kenefick, in closing: I want to thank the members for their kind discussions. There are a few points I wish to mention. Dr. White mentioned the possibility of lung cysts as a cause of pneumothorax. A number of these cases have been reported. I know of two cases where x-rays taken at the time of the pneumothorax showed a cyst which had ruptured and remained after the lung collapse. I believe in Kjaergard's monograph there is a nice picture of a lung cyst with a pneumothorax.

Dr. Goltz mentioned the differences of opinion as to the incidence of tuberculosis in these cases. I think that is perfectly true. Men who are doing most of their work with tuberculosis in institutions have an idea that these are all tuberculous because they are dealing mostly with tuberculosis. On the other hand, in private practice one probably sees many more cases of the simple type.

Dr. Hoffman mentioned the injection of glucose. This is recommended in cases of hemopneumothorax to cause the blood to clot. The injection of sterile water or glucose, or almost any foreign protein, seemingly causes coagulation and stops the hemorrhage.

These cases are mainly of interest because of the prognosis. If one takes for granted that these patients are tuberculous and keeps them in bed for a long time with the stigma of tuberculosis, naturally they lose much time. With the use of the Montoux test, a large percentage of these cases are proven not to be tuberculosis.

The meeting adjourned.

A. G. Schulze, M.D., *Secretary.*

ACUTE LYMPHATIC LEUKEMIA WITH REMISSION (CASE REPORT)

(Continued from Page 501)

area of consolidation or dulness in the left base had disappeared entirely by April 9, leaving normal breath sounds. The child seemed to gain a little in strength, her color improved, she was brighter, she responded better and on April 6 began to eat rather generous amounts of solid food, the first solid food she had taken for two weeks. Her pulse became somewhat slower, changing from 140 and 150 to 130. The temperature, however, was never less than 100 by axilla and it would rise very easily to 104 by axilla. On April 9, her white count was 64,000, a reduction of almost 100,000 cells per cm. over a period of ten days. The blood smear continued to show the typical picture of acute lymphatic leukemia. From March 30 to April 10 eight injections of liver extract were given. April 9, a pink generalized maculopapular eruption was first observed. This persisted until her demise five days later.

April 10, the patient began definitely to lose ground. Bleeding from nose, mouth, and rectum began. Breathing was rapid and shallow. The pasty pallor returned and the responses were very poor. There were a few scattered leukemic infiltrations in the skin still remaining, but neither did these increase nor did any areas of dulness return to the chest. Indeed, the skin nodules from the time they began to subside until exitus continued to do so although much more slowly the last few days. April 11, the child had a few mild convulsions. General appearance was one of pallor, bloating, extreme toxicity. Exitus occurred April 14.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

HANDBOOK OF ORTHOPÆDIC SURGERY. Alfred Rives Shands, Jr., M.D., and Richard Raney, M.D. 593 pages. Illus. $5.00. St. Louis: Mosby, 1937.

I find this an adequate outline covering the subject adapted to the needs particularly of students. The drawings illustrate deformities and bone pathology in many cases better than the average photographs of radiographs. The bibliography is comprehensive and well organized and the index accurate.

S. W. Shimonek

MODERN TREATMENT AND FORMULARY. Edw. A. Mullen, M.D. 707 pp., $5.00. Philadelphia: F. A. Davis Co., 1936.

Anyone interested in the essentials of treatment including numerous authenticated prescriptions, and diet lists, tables of differential diagnosis, and other valuable data and tables, will find these compactly embodied in this well-organized and readable volume. It should prove a valuable handbook, particularly for the general practitioner.

Thomas Myers, M.D.

MANAGEMENT OF THE SICK INFANT AND CHILD. By Langley Porter and Wm. E. Carter. 5th Ed., 874 pp. $10.00. St. Louis: C. V. Mosby Co., 1938.

This excellent discussion has been justly popular, having gone through six printings in sixteen years. Despite its title, the work is not limited solely to a discussion of treatment, but also devotes ample space to etiology, symptomatology, and description of the various manifestations of diseases. Over two hundred pages are devoted to a well-illustrated discussion of methods of treatment, briefly and simply outlined. Diets in disease and health are competently described, and appropriate recipes and tables are included. A valuable chapter on drugs with appropriate prescriptions and dosage in various conditions completes this volume. The typography and excellent paper used make the book easily readable. Certainly this is an indispensable addition to the library of anyone treating children.

Thomas Myers, M.D.

INJECTION TREATMENT OF VARICOSE VEINS AND HEMORRHOIDS. H. O. McPheeters, M.D., and James Kerr Anderson, M.D. 315 pages. Illus. $4.50. Philadelphia: F. A. Davis Co., 1938.

The section on injection of varicose veins by H. O. McPheeters is a very comprehensive treatise on the anatomy, embryology, etiology and diagnosis of this condition. There is an excellent and clear description of the physiology involved and of the Trendelenburg test. The chapters on treatment are extremely clear and easily followed. The few hours necessary to read this is time well spent.

The section on the injection treatment of hemorrhoids by James Kerr Anderson is the clearest, most concise, and most thorough description of this subject that one can find. The chapters are written with clearness and brevity that is welcome. Obscure points are brought forth in easily understood terms and there is no doubt in the reader's mind as to the author's meaning. It is well worth reading by everyone who contemplates injecting or is injecting hemorrhoids. The reading time is a little over an hour.

Wallace P. Ritchie

IN MEMORIAM

(Continued from Page 513)

whom I have ever known. Intolerant of anything but the highest type of professional conduct, he was never influenced by anything commercial in his professional life. He maintained in his surgical diagnosis and technic a perfection that few attain.

The life and work of the medical man are brief and often too soon forgotten but the great principles of ethical conduct to which he was committed are age-old and permanent. I like to believe that the memory of Dr. Wiese will live for all time in these great principles.

Claude C. Kennedy, M.D.

L. G. Wilberton

1853-1938

Dr. L. G. Wilberton, a practicing physician at Winona for fifty-eight years, died at his home there on May 29. Dr. Wilberton was reared in New York State, and was a graduate of Hahnemann College at Philadelphia, in the class of 1880, coming to Winona directly after his graduation. Surviving him are his wife and two children, Mrs. Ernest E. Shepard of Winona and George L. Wilberton of Seattle, Wash. Dr. Wilberton was a member of the American Institute of Homeopathy and for a time was vice president of the Minnesota State Homeopathic association. He was the oldest homeopathic physician in Minnesota.

CARCINOMA OF THE COLON AND RECTUM*

IRVIN ABELL, M.D.

Louisville, Kentucky

MALIGNANCY of the large bowel is a frequently noted lesion and, as with carcinoma elsewhere, the picture is not a bright one. The age at which its greatest incidence is observed and the relentless character of the disease with its consequent reduction of an already waning vitality combine to make the operative mortality a high one, while the number of patients remaining permanently free from disease following operation is discouragingly small. Unfortunately, with few exceptions, this is the usual history of cancer in other parts of the body; and yet there are certain features about cancer of the colon, notably its slow growth with tardiness of metastasis to readily removable groups of lymph nodes, which should make the outlook more favorable, with the opportunity for radical treatment which an early diagnosis affords. This study is presented as a plea for the early recognition of the disease and its radical removal, the two factors which in the light of our present knowledge offer the only hope of its eradication. The material upon which this paper is based comprises 200 patients with carcinoma of the large bowel, including the rectum, observed since 1915, the growth being in the colon in 125 and in the rectum in seventy-five. Of this number, eighty-nine (sixty-four in the colon and twenty-five in the rectum) were subjected to radical operation. In sixty-nine, some type of palliative operation, colostomy or a short circuiting ileocolostomy or colo-colostomy was done. In three the lesion was removable, but the operation was declined, while in thirty-nine the condition was such as to preclude any advantage from operative measures. The fact that but 44.5 per cent of patients came under observation at a time when radical measures could be instituted, 34.5 per cent at a time when palliative measures only could be employed and 19.5 per cent when neither method of possible relief was available, indicates a woeful disregard of symptoms on the part of the patient and a failure on the part of the physician to appreciate their significance, meaning that 54 per cent of the series were denied the chance of cure which surgery offers. Of the 125 patients in whom the growth was found in the colon, two were in the second decade, one a boy of seventeen with a colloid carcinoma of the transverse colon, the other a girl of nineteen with the lesion in the cecum; four were in the third, eleven in the fourth, twenty-six in the fifth, thirty-one in the sixth, thirty-five in the seventh and fourteen in the eighth decade, with the age not stated in two. It will be noted that fifty-seven, or approximately 62 per cent, were between the ages of fifty and seventy, a period in which the duration of life alone takes its toll in the wear and tear upon the vital functions. Of the seventy-five in which the lesion was situated in the rectum, two occurred in the third decade, in women of twenty-one and twenty-eight, four in the fourth, sixteen in the fifth, twenty-five in the sixth, sixteen in the seventh and twelve in the eighth decade. It will be noted again that forty-one, or 54.7 per cent, occurred between the ages of fifty and seventy, and fifty-three, or 70 per cent, between the ages of fifty and eighty. This great incidence of the disease in advanced life serves in part to explain both its high operative mortality and the paucity of five and ten year cures.

*Presented at the eighty-fifth annual meeting of the Minnesota State Medical Association, Duluth, Minn., June 29, 1938.

The carcinoma was situated in the cecum in thirty-six, in the cecum and transverse colon in two, in the ascending colon in thirteen, in the hepatic flexure in thirteen, in the transverse colon alone in fourteen, in the transverse colon and right ovary in one, in the splenic flexure alone in ten, in the splenic flexure and right ovary in one, in the descending colon in eight, in the sigmoid colon in twenty-seven, in the rectum alone in seventy-four, and in the rectum and breast in one. Sixty-four were in the right colon, fifteen in the transverse and 121 in the left colon and rectum. It will be noted that five patients are recorded as having multiple foci, two with carcinoma of the cecum and transverse colon, two with carcinoma of the colon and ovary and one with carcinoma of the rectum and breast. Together they present a fertile field for speculation as to whether or not they represent primary multiple foci. The conception that cancer is primarily local in origin, the secondary tumors developing as the result of metastatic transplantation, is so definitely fixed that one accepts the idea of multiple primary foci with a certain amount of reserve. Billroth formulated three conditions to be fulfilled by multiple cancers before their acceptance as individual and independent tumors: (1) there should be histological differences of such degree as to preclude the interpretation of the two growths as representing different stages of development; (2) each growth must spring from its parent epithelium; and (3) each growth must have its own group of metastases. Mercanton adds a fourth condition to the effect that if, after the removal at one operation of two cancers, the patient remains free from disease, it is practically certain that the two growths were independent, since had either been a metastasis it would be entirely reasonable to assume the presence of other metastases, a state of affairs incompatible with life.

Of the two instances in which cancer was noted in the cecum and transverse colon, one probably represents metastasis by transplantation; the other may represent multiple primary foci. The former, a woman of sixty, presented a large carcinoma of the cecum with two polypoid tumors distal to it, one in the hepatic flexure and one in the transverse colon. Both of the distal tumors showed a microscopic structure identical with the parent growth. No other metastases were found. This patient is now living and well six years following operation. The second patient affords a somewhat different picture. A man, aged 40, had a tumor of the cecum 3.2 inches in its greatest diameter, and one of the transverse colon 2.4 inches in its greatest diameter. Microscopical examination revealed the cecal tumor to be a colloid carcinoma, the transverse colon tumor to be an adenocarcinoma. No metastasis to the lymph nodes was found. The size of the tumors, their histological structure and the duration of life following their removal suggest the possibility primary multiplicity. Metastasis commonly occurs by a path leading away from the tumor, but there is always the possibility of metastasis by retrograde or other circuitous routes. Lymphatic metastasis may occur by way of the mesentery to its root, and, finding continued progress in this direction blocked, may extend by retrograde route to another point in the colon. Dissemination or implantation metastasis is recognized in which cancerous cells float off in the peritoneal fluids and produce secondary growths in the pelvic peritoneum. Similarly, cells from a parent growth involving the mucosa of the colon may become implanted and give rise to secondary growths distally situated from it. Such growths are usually smaller, indicating more recent origin, and they present the same histological structure as the parent tumor. This mode of transmission accounts satisfactorily for multiple growths of similar structure which involves the lumen, with the exception of those observed in polyposis. The colloid cancers observed in the colon are fundamentally adenocarcinoma in which the cells, while retaining the power of forming mucin, are nevertheless unable to excrete it properly. Microscopically they differ from adenocarcinoma in that the acini are filled and more or less distended with hyaline or granular basophilic mucin.

It is generally accepted that metastatic tumors from primary ones which produce colloid may continue to produce material like the primary tumor, or may fail to do so; and, in addition, that metastatic tumors very seldom or never produce colloid, if the tumor from which they have arisen does not produce colloid material. The difference in structure and the fairly wide separation of the two tumors argue for primary multiplicity. This patient was operated upon in 1927, the terminal ileum and the right half of the colon being removed to a point beyond the

location of the second growth. He remained well for six years, returning in 1933 with an adenocarcinoma involving the descending colon which at that time was removed. At the present time, eleven years after the first operation and five years after the second, he shows no evidence of further growth, affording interesting material for speculation as to whether each tumor represented a primary focus, or as to whether the second and third ones were but instances of mucosal implantation with the third one showing unusually slow development. Both cases could well seem to bear out the hypothesis that carcinoma of the colon originates in polyps and that each growth represented a separate and primary focus.

Of two patients with cancer of the colon, one a scirrhous adenocarcinoma of the transverse colon, the other an adenocarcinoma of the splenic flexure, both presented papillary adenocarcinoma of the right ovary. The difference in histological structure and the widely separated sites of origin in unrelated organs strongly suggest primary multiplicity.

The fifth instance in which multiple foci were noted occurred in a woman of fifty-nine who presented a tumor in the rectum and one in the breast. Microscopical examination showed the rectal tumor to be a colloid carcinoma, columnar cell, arising from the mucosa and not the mucous glands. The breast tumor was an adenocarcinoma, polygonal cell, primary in the mammary gland. The coincident development of the growths in widely distant and non-related organs, the one a polygonal cell, the other a columnar cell colloid carcinoma, together with the similarity between the cells of the neoplasms and those occurring in their respective sites, would argue for their independence, while their basic structure, adenocarcinoma, introduces an element of doubt which cannot be convincingly eliminated.

But one instance in the series showed carcinoma developing in diffuse polyposis. A man, aged 29, gave a history of intermittent bleeding since the age of twelve. Sigmoidoscopic examination showed the presence of multiple polyps in the upper rectum and lower sigmoid, varying in diameter from one-eighth to one-fourth inch. X-ray film of the colon showed a diffuse polyposis with a defect in sigmoid suggestive of carcinoma. The rectal polyps were destroyed by fulguration and the colon excised. It presented extensive polyposis from the ileocecal valve to the rectum with adenocarcinoma in the sigmoid. It has been argued that all cancers of the colon and rectum have their origin in polyps, an hypothesis in which, from our experience, we cannot concur. Doering noted that carcinoma occurred in 43 per cent of cases of polyposis and pointed out that this accounts for some of the cases of carcinoma occurring in early life. It is recognized that polypi are the most frequent precancerous lesions noted in the colon and rectum, but it is not possible to state with assurance that they invariably precede the development of cancer in these situations.

Of the 125 patients with cancer of the colon, eighty-eight were males and sixty-seven were females. The symptoms in this group have shown rather wide variation. Digestive disturbances have been the rule, in some instances constituting the sole complaint causing the patient to seek relief. Weakness and pallor were given by five as the only complaints. Weight loss has been noted in more than 50 per cent, varying from several to ninety pounds. Diarrhea with and without bloody stools has been noted in lesions involving all parts of the colon, the diarrhea being more frequent when the cancer involved the right colon, the bloody stools more frequent when the left colon was the site of the growth.

Constipation and obstipation were noted in but eighteen of the sixty-two cases in which the growth was situated in the right half of the colon, but were frequently present when the lesion involved the left half of the colon. Pain was the chief complaint given by forty-one; in most of these, this symptom was to be attributed to a partial obstruction. Obstruction was noted in fifty-nine, or 62.5 per cent, thirty being of the acute and twenty-nine of the chronic variety; sixty-six, or 57.8 per cent, presented no obstructive symptoms. While obstruction occurs with lesions in all parts of the colon, it was more frequent in the left than in the right half, the explanation being found in part in the fluidity of the feces in the right colon as compared with the solidity of the feces in the left colon. Again the annular, scirrhous or fibrocarcinoma, producing marked constriction of the lumen of the bowel, has been in our series more common in the left than in the right half of the colon. The anatomical arrangement of the angles favors the development of obstruction when these parts are

the seat of growths. This is especially true of the splenic flexure, acute obstruction not infrequently being the first subjective symptom of cancer at this point. The cecal and ascending colon cancers as a rule have been either the soft medullary adenocarcinomas or of the colloid type, the former more frequent than the latter. The soft, medullary growths occurring in the cecum and ascending colon produce rather large tumors, the early ulceration and infection of which lead to rather marked anemia, disturbance of digestion and weight loss, although they may still be limited to the bowel and readily operable. The blood picture has been somewhat significant, the greatest percentage of low counts being found in involvment of the cecum and ascending colon. In fifty-one patients with the growth in these situations the lowest hemoglobin was 32, the highest 90, the average being 72 per cent. The red cells varied from three to five million, the average being slightly under four million. The average hemoglobin in growths of the transverse colon was 76.3; splenic flexure, 77.2; and in the sigmoid, 72.8; the red cell average was, respectively, 4,250,000, 4,350,000, and 4,000,000.

Perforation of the growth with abscess formation was noted in three instances: in two, the growths being of the medullary type situated in the cecum and in one of the scirrhous type in the descending colon. Perforations may occur in any type of cancer and at all points of the bowel, adding greatly to the difficulty and danger of removal, granting its operability. In one of these, nothing more than a palliative colostomy could be undertaken, the patient surviving eight months; in the remaining two, recession of the growth and sinus in the abdominal wall was carried out. One patient died from postoperative peritonitis, the other at the end of four weeks from wound infection. A palpable mass was present in sixty-five, none being detected in sixty. The distention accompanying acute obstruction as a rule effectively hides the mass; in the non-obstructed cases, the growths situated at the flexures and the annular, stenosing ones in the descending colon and sigmoid do not readily lend themselves to detection by palpation, particularly in the presence of a thick abdominal wall. The masses in the ascending and descending colons are usually detected in the abdomen at points corresponding to the usual course of the bowel. Those at the flexures are fairly constant in their situation due to the fixation of the bowel at these points. The mobility of the transverse colon is such, at times, that masses originating therein may be felt at any part of the abdomen; cecal masses usually remain in the right lower quadrant, but in the event of the tumor originating in a mobile cecum quite a range of motion and consequently of location will be permitted. X-ray examination has shown constantly two manifestations, filling defects and obstructions, upon neither of which alone can the diagnosis of cancer invariably be made. Syphilis, tuberculosis, pericecal inflammations and diverticulitis may each and all, at times, give x-ray manifestations indistinguishable from those produced by cancer. The barium enema rather than the barium meal has been employed, since the distention of the bowel wall by the former gives clearer definition both under the fluoroscope and on the film. Sigmoidoscopy will reveal growths too low to be shown by the x-ray and too high to be felt upon digital exploration of the rectum, and should constitute a step of the routine examination. A correlation of the history with the physical, laboratory, x-ray and sigmoidoscopic findings will reduce to a minimum the chance for error in detection and diagnosis. Of the sixty-four patients with cancer of the cecum, ascending colon and hepatic flexure, including two with additional tumors in the transverse colon, thirty-eight were subjected to radical and fourteen to palliative operations, twelve being classified as non-operable. The radical operation has consisted in the removal of six to eight inches of the terminal ileum and the colon from the cecum to the junction of the proximal with the distal two-thirds of the transverse colon. In two patients whose cecum and transverse colon both contained tumors the resection was made to include the proximal two-thirds of the transverse colon.

The reasons for such extensive removal when the growth is situated in the right half of the colon are to be found in the embryological, physiological and anatomical differences between it and the left half. Embryologically, the ileum and right half of the colon as far as the midportion of the transverse colon are derived from the midgut, whereas that portion of the colon distal to the midportion of the transverse colon arises from the hindgut. The lymphatic drain-

age of the right colon is relatively scant, whereas that of the left is more abundant. The blood supply of the right half, through the ileocolic artery is very constant; that of the left half is variable. The contents of the two halves of the colon also differ. In the proximal colon the contents are fluid and less septic, whereas in the distal colon the fecal contents are more solid, are formed and contain a larger number of organisms. These factors conduce to the maintenance of a more satisfactory technic and to the safe removal of the ileocolic and right colic glands. In addition, there is greater ease and safety in securing union between the small intestine and colon, as contrasted with resection of the cecum and ascending colon, in continuity. In the earlier cases closure of the ends of both colon and ileum with side-to-side anastomosis, suture method, was done. Later, closure of the end of the colon with end-to-side anastomosis with Murphy button was employed, and latterly, closure of the end of the colon with end-to-side anastomosis with Rankin clamp has been practiced. All three methods are satisfactory, but the latter has the advantage of simplicity, ease of execution and greater freedom from infection.

There were ten operative deaths, three on the fourth day and two on the fifth day from peritonitis. One seventy-six-year-old man died from anuria on the ninth day. A portion of the ureter had been removed on account of its incorporation in the tumor, the proximal end being ligated. One patient died on the twenty-first and one on the thirty-fifth day from myocardial failure. A man whose abdominal wall was resected because of tumor perforation died at the end of the fourth week from infection, and one from bronchopneumonia at the end of the fifth week. Eight of the deaths occurred in twenty-six one-stage resections, a mortality of 30.7 per cent, as contrasted with two deaths in fourteen two-stage resections, a mortality of 14.2 per cent. In thirty-four patients in whom the neoplasm was situated in the splenic flexure, transverse and descending colon, radical operation was done in eighteen, a palliative operation in thirteen, and three were classed as inoperable.

Of the eighteen radical operation, ten were two-stage and eight were one-stage procedures. There were four operative deaths, three following one-stage operations, two on the third day from peritonitis and one on the thirtieth day from pulmonary abscess following septic infarct, and one following a two-stage operation.

Of the twenty-seven patients with cancer of the sigmoid, thirteen had radical and eleven had palliative operations, three being inoperable. Of the radical operations, seven were one-stage resections, five were two-stage resections, and one consisted of colectomy for diffuse polyposis with carcinoma in the sigmoid. There were four operative deaths, one from myocardial failure eight hours after operation and three from peritonitis, on the first, sixth and eighth day, respectively.

Resection of the left half of the colon in continuity undoubtedly carries a higher primary mortality than the Mikulicz operation and was selected because of the opportunity it affords for removing the mesocolic glands and avoiding the 7 per cent of abdominal wall metastases noted in the latter procedure. It is believed that the added ultimate security given by such removal justifies the primary increased risk. It is generally conceded that in the presence of obstruction a decompression by means of an enterostomy or ileocolostomy proximal to the barrier offered by the growth, followed by rehabilitation before carrying out the resection of the involved segment, will greatly enhance the safety of the secondary procedure. The absorbed toxins lower the resistance of the patient, the thickening and edema of the obstructed intestine interfere with its vitality and render asepsis difficult to maintain, while the abdominal distention hampers both technic and manipulation. Decompression and rehabilitation will save lives that would be lost if the radical operation were attempted under such adverse conditions. The same principle has been widely applied in all resections of the left half of the colon. Our experience leads us to the belief that the application of this principle in the treatment of all cancers of the colon, regardless of their location, is a necessary factor in the further reduction of operative mortality.

Of the seventy-five patients with cancer of the rectum, twenty-nine were males and forty-six were females. The symptoms were pain, tenesmus, constipation, bleeding and discharge with secondary disturbances of digestive function and obstruction appearing late in the course of the disease. The average duration of symptoms was fourteen months; the shortest, one

month; and the longest, six years. The blood picture varied with the stage of the disease and the extent of the bleeding. Little need be said about the diagnosis since the rectum is susceptible of both palpation and visual examination In sixty-two of the seventy-five, a mass could be palpated upon digital examination, while but thirteen required the proctoscope for detection. It is only when one fails to employ these two measures that the lesion can be overlooked. The microscope may be required for the positive determination of malignancy, the eye and the finger being sufficient for the determination of the presence of tumor. Some excuse may be offered for delay in recognizing cancer of the colon, none for failure to recognize cancer of the rectum. The one in a closed cavity may elude any but the most careful examination, the other sufficiently near the surface to be seen and felt will be detected if looked for. The so-called conservative operations for cancer of the rectum in which an attempt is made to retain the sphincter muscle have been disappointing in that recurrence frequently follows. Conservatism, when dealing with malignancy, conserves the disease, not the patient. There are two potent objections to the Kraske operation in that it does not afford access to all of the lymph nodes to which the rectal lymphatics pass and in that it leaves the artificial anus in a most inconvenient site. The two-stage operation evolved by Coffey, in which a permanent colostomy is first made and later followed by removal of the distal portion of sigmoid, mesosigmoid, rectum, perirectal fat and lymph nodes, appeals as being based on sound principles in that it removes the rectum and cancer-bearing lymphatics that drain it. The first stage affords opportunity for accurately determining the operability, enabling one to avoid unnecessary resections. The Miles one-stage operation offers the same opportunity of recognizing inoperability, insofar as removal of the growth is concerned, and of selecting a palliative procedure based upon the pathology revealed upon abdominal section. Of the seventy-five patients in this group, twenty-five had radical operations, twelve two-stage and thirteen one-stage; twenty-eight had palliative colostomies, nineteen were inoperable and three, while operable, refused operation. In the twenty-five radical operations there were six deaths, one at the end of twenty-four hours following the first stage, cause unknown; two from peritonitis at the end of fifty hours following the second stage, one on the ninth day from cardiorenal failure, and two from broncho-pneumonia.

Operations done for cancer of the colon and rectum, as is true of all operations for cancer, must be complete in that the tissue involved and the tissue apt to be involved must be removed in all cases if a satisfactory percentage of cures is to be expected. This necessitates a knowledge of the characteristics of the growth, the methods of spread and the paths it takes as well as a thorough knowledge of the anatomy and physiology of the part involved. The blood supply and lymphatic distribution of the colon and rectum necessitate and permit of radical removals, the loss of such part or parts being readily physiologically compensated. The operability of the growth, except in advanced cases, cannot be accurately forecast until the incision is made; it will then be determined by the local attachments and visible spread of the growth and by distant metastases. Attachment to adjacent organs does not always contraindicate radical ablation if the attached and involved organ is susceptible of removal. Such extension militates against the probability of permanent cure, but the prolongation of life and comfort thereby obtained makes the removal worth while. We have resected the ureter, the ileum, the uterus, the vagina, and the abdominal wall without influencing the immediate result. The enlargement of adjacent lymph nodes often presents a problem not soluble without microscopic examination. The nodes tributary to the right colon are commonly enlarged when the cecal growth is ulcerated and infected. Microscopical examination has shown both metastatic deposit and toxic lymphnoditis, it having been impossible in some instances to make the distinction on other grounds. In view of such findings the presence of enlarged lymph nodes at this point should not deter one from doing a radical removal. This is true in far lesser degree in cancers of the left colon. In our experience the hard dense nodular enlargement indicative of metastatic deposits has been more frequently noted.

A summary of the results in the 200 cases coming under observation before 1938 shows that eighty-nine were subjected to radical operation and sixty-nine to palliative operation, while

in forty-two the lesion was so advanced that surgery offered no relief, or was refused. The eighty-nine radical operations done during this period show a total operative mortality of 27.4 per cent. There is, however, an appreciable difference in the mortality of operations done during the first fifteen years of this period, contrasted with those done during the last decade. In the first period, one-stage operations without utilization of modern methods of rehabilitation was the rule, while in the latter period multiple-stage operations with decompression, transfusions and other methods of increasing resistance have reduced the total mortality to approximately 12 per cent. As an immediate cause of death, bronchopneumonia takes first place, with peritonitis and uremia accounting for an equal number in the second division; shock was a cause of death in two instances and pulmonary emobolism in one. Of the patients surviving the operation, approximately 60 per cent have survived for five years and 24 per cent for ten years or longer. The percentage of five and ten-year cures, 60 and 24 per cent, respectively, is gratifying, but the saving of life has been pitiably small when the total number of cases under observation is taken into consideration. It is to be hoped that the widespread interest manifested in the cancer problem today, together with the reassuring knowledge that the disease within certain limitations is curable, may result in bringing an increasingly greater number of patients under professional scrutiny sufficiently early to give them the chance for cure which surgery offers.

PROBLEMS ASSOCIATED WITH THE CLINICAL RECOGNITION OF PULMONARY HYPERTENSION

THOMAS J. DRY, M.B.

Rochester, Minnesota

A VARIETY of pathologic conditions, some of which are admittedly rare, result in increased pressure within the pulmonary circuit. Since there is no practical method of determining the blood pressure of the lesser circulation, the clinical recognition of pulmonary hypertension depends on the recognition of secondary effects resulting from its presence and on a knowledge of the different etiologic factors capable of producing pulmonary hypertension.

In some instances the primary disease of which pulmonary hypertension is a part or a consequence may somewhat obscure and distort the picture, but, if a deliberate attempt is made, the essential findings can usually be readily elicited. Since the presence of pulmonary hypertension affords information of prognostic importance, its recognition is of more than mere academic interest.

Physiologic Considerations

In discussing conditions affecting the pulmonary arterial tree it is important to visualize clearly the functional continuity and the anatomic relationship that exists between the systemic and pulmonary circulations (Fig. 1). The physiologic purpose of the right side of the heart is to convey venous blood to the alveolar system of the lungs, where gaseous exchanges occur. The physiologic purpose of the left side of the heart is to distribute the same blood after oxygenation to the systemic circulation. These two units are inseparable and a disturbance of function in one will sooner or later influence the other.

Another important consideration in understanding pulmonary arterial disease is the concept of a "vascular reserve." The pulmonary arterial tree, like the remainder of the vascular system, is endowed with a vascular area and a capillary bed greater than ordinary functional demands can exceed.

Among experimental subjects, Haggart and Walker have shown that 52 to 66 per cent of the pulmonary circulation could be cut off without significant variation in the general circulatory condition. The point at which failure occurs is sharply defined, and beyond this point circulatory collapse is precipitated by even a minute increase in the arterial obstruction. Underhill sums up the position as follows: "The healthy heart, therefore, can accommodate itself with-

*From the Section on Cardiology, The Mayo Clinic, Rochester, Minnesota.

out difficulty to sending the same volume of blood through one lung only, in a given time, as it previously sent through both."

The presence of structural changes in the pulmonary circuit, therefore, does not imply necessarily that there has been any limitation of function. As long as the "reserve" is not encroached on to a serious extent, symptoms may be in abeyance and the cardiorespiratory apparatus may adapt itself to new conditions and remain compensated.

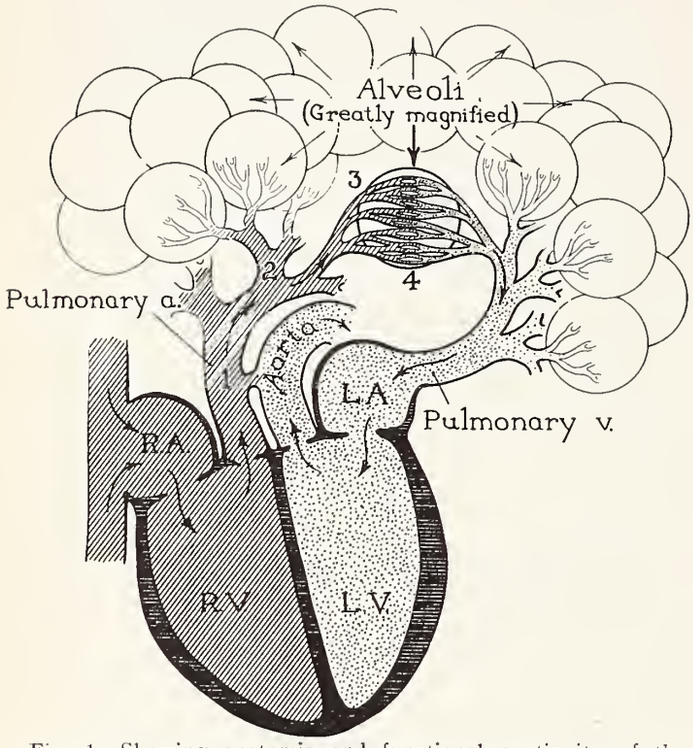

Fig. 1. Showing anatomic and functional continuity of the systemic and the pulmonary circulation. Pressure in the pulmonary circuit is increased when the left ventricle fails, when there is obstruction either at the mitral orifice or within the pulmonary circuit itself and when an extra quota of blood is shunted into the pulmonary circulation. This diagram further suggests the conception of a "vascular reserve."

The Results and Effects of Pulmonary Hypertension

Any mechanism which leads to increased pressure in the pulmonary circuit, irrespective of its mode of production, increases the work of the right ventricle and, if sustained, as it usually is, will lead to hypertrophy of that chamber. As secondary effects on the pulmonary vessels themselves, there follow arteriosclerotic changes in the main pulmonary arteries and added obstructive effects in the arterioles. Over a period of time, when the reserves are exhausted, failure of the right side of the heart may ensue with resultant dilatation, venous congestion and edema. When pulmonary hypertension is the result of obstruction within the pulmonary circuit, the interference with ventilation and the resulting anoxemia eventually exert deleterious effects on the nutritional status of the left side of the heart, and so set up a vicious cycle. As Waring and Black point out, the collateral circulation which may be afforded by the bronchial arteries cannot, in any way, compensate for the respiratory difficulties, inasmuch as those vessels carry oxygenated blood.

Etiologic Factors and the Manner in Which Each Causes Pulmonary Hypertension

The conditions resulting in increased pressure within the pulmonary circuit are varied, but they can be arranged conveniently into two groups, depending on the mechanism involved: (1) obstruction to the pulmonary circuit either beyond or within the pulmonary system and (2) arteriovenous shunts in certain cases of congenital heart disease.

Obstruction of the pulmonary circuit.—Obstruction beyond the pulmonary circuit. Mitral stenosis constitutes the classic example of a mechanical obstruction to the circulation beyond the pulmonary circuit. This results in increased pulmonary pressure. Oxygenation is not interfered with until compensation fails, because the obstruction is beyond the alveolar system. Enlargement of the left auricle eventually results.

A failing left ventricle, for any cause, be it systemic hypertension, aortic disease or myocardial degeneration, results in a similar train of events. With rise in pulmonary pressure, the right ventricle is compelled to contract against an increasing load. Dilatation of the left ventricle in the process of failure may be associated with two events which further embarrass the right side of the heart, namely, mitral insufficiency and bulging of the interventricular septum into the right ventricle, constricting its capacity and thereby interfering with emptying of the right auricle. Thompson and White have shown that the effects on the right side of the heart resulting from left-sided strain alone may proceed to preponderant hypertrophy of the right ventricle and, in some cases, electrocardiographic examination gave evidence of right axis deviation. Accentuation of the second pulmonic sound in the course of hypertensive heart disease represents the clinical counterpart of such a state of affairs.

Obstruction within the pulmonary circuit. The obstruction may be at various levels of the pulmonary arterial tree.

I. The main pulmonary vessels.

A. Acute cor pulmonale. The sudden closure of a large pulmonary branch results in an equally sudden pulmonary hypertension, presumably because of arterial spasm in the associated pulmonary radicles. If the accident is not fatal, the evidence of strain of the right side of the heart usually can be elicited clinically and electrocardiographically.

B. Thrombosis of the pulmonary artery. A number of cases have been reported which presented clinically a picture of pulmonary hypertension and culminated in hypertrophy and failure of the right side of the heart. At necropsy, multiple thrombosis, the origin of which was obscure, was found occluding many of the larger pulmonary branches. The reader is referred particularly to the reports of cases of Means and Mallory, Montgomery, Jump and Baumann, and Barnes and Yater exemplifying this group. In the last named case, the history suggested that the arterial occlusions were of embolic origin.

II. Small and medium-sized pulmonary branches.

A. Sickle-cell anemia. The occurrence of cardiac enlargement, systolic murmurs and a palpable liver simulating rheumatic heart disease, has been noted frequently in asociation with sickle-cell anemia, when, at necropsy, evidence of valvular heart disease was not discoverable.[6] The assumption that these findings were the result of the anemia of itself has been questioned by Yater and Hausmann, who have reported illustrative cases in which the picture of failure of the right side of the heart was shown to have been caused either by thrombotic occlusion of the small and medium-sized arteries of the lungs or by thickening of the walls of the small and medium-sized arteries and the arterioles of the lungs with reduction in the size of their lumens, but without thrombotic occlusion. Capillary stasis, owing to distortion and agglutination of erythrocytes, was felt to be the essential factor in producing these arterial lesions.

B. Carcinomatous lymphangitis associated with obliterative pulmonary arteritis resulting in failure of the right side of the heart was described by Girode as early as 1889 according to Greenspan, who, in addition to reporting four such cases, gives an excellent and extensive review of the literature. The essential picture consists of widespread occlusion of arteries and arterioles apparently secondary to perivascular lymphatic infiltration with carcinomatous cells and proliferation of connective tissue incidental to this. Carcinomatous emboli occur within the vessels but play a relatively unimportant rôle in the obliterative process. By far the majority of cases result from a spread by way of the lymphatic vessels from a primary lesion in the stomach. The clinical course in such cases is much less protracted than in all other forms of chronic cor pulmonale, and, thus, the term subacute cor pulmonale, as applied by Brill and Robertson, seems entirely justifiable.

C. Schistosomiasis (Mansoni) has been shown to cause granulomatous pulmonary lesions within or related to the blood vessels. On examination, many small arteries gave evidence of extreme concentric thickening of the intima with diminution of the size of the lumen and hypertrophy of the media in the case reported by Clark and Graef. Right ventricular hypertrophy and congestive heart failure were present and there was no other ascertainable factor which might have caused pulmonary hypertension. It will be recalled that infection occurs through the skin and that the parasites are carried by the bloodstream to the lungs, through which they are carried to be distributed by the systemic circulation, but ending mainly in the portal system. However, residual infestation in the lungs apparently can occur with secondary effects in the pulmonary vessels sufficiently widespread to cause pulmonary hypertension.

III. Pulmonary arterioles.

A. Secondary pulmonary arteriolar sclerosis occurs in association with a wide variety of conditions such as those already discussed, in certain cases of mitral stenosis, emphysema and pulmonary fibrosis, but these changes are not always sufficiently widespread to cause pulmonary hypertension in themselves.

B. Primary pulmonary arteriolar sclerosis is a rare and interesting entity in which no cause for these widespread arteriolar changes is ascertainable in either the pulmonary system or the cardiovascular apparatus (Fig. 2).

IV. Capillary system. When obstruction occurs to radicles of the pulmonary artery at levels proximal to the capillary bed, it is apparent that

the corresponding sets of capillaries also are put out of commission automatically. Similarly, when the left side of the heart fails, capillary function is interfered with even if the capillaries are not

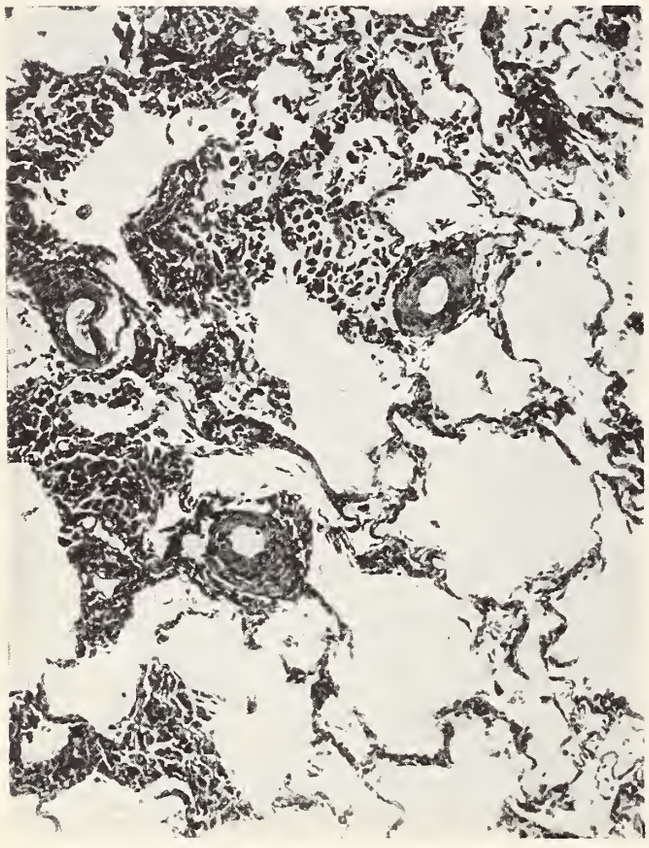

Fig. 2. Pulmonary tissue; sclerosis of the pulmonary arterioles with considerable diminution in the size of their lumens.

altered structurally. Obliteration of portions of the capillary bed results further as a consequence of a group of pulmonary diseases, chief among which are emphysema (through destruction of the interalveolar walls) and widespread pulmonary fibrosis (which destroys portions of pulmonary tissue). Both these conditions, as a rule, are associated with chronic bronchitis, also asthmatic bronchitis and emphysema coexist in many instances. It is apparent that obliteration of the capillary bed must be much more widespread and extensive in order to exhaust the vascular reserves and to cause pulmonary hypertension than when the larger radicles of the pulmonary arterial tree are involved in such a process. This is an important point to grasp because it has a direct bearing on the controversy concerning the rôle of emphysema in the production of pulmonary hypertension.

The association of emphysema and asthma with hypertrophy of the right side of the heart and congestive heart failure finds expression in the literature of the later Eighteenth Century and out of these observations the term "emphysema heart" was born. The historical background of our present conception of emphysema and its effects on the heart was adequately described by Parkinson and Hoyle in a recent article. This problem cannot be pursued without incorporating two important observations in the discussion. The first is that advanced pulmonary emphysema may not be attended by hypertrophy of the right ventricle, increased venous pressure or other evidence of congestive heart failure and the circulation time through the pulmonary circuit may be within normal limits even in the terminal stages of the disease. There may actually be some venous engorgement associated with emphysema without any increase in venous pressure; however, this venous engorgement is the result mainly of increase in the intrapleural pressure which interferes with drainage of the venous blood into the right auricle. The second observation is that whenever pulmonary arteriolar obliterative changes are found, irrespective of the circumstances, hypertrophy of the right ventricle is present in a high percentage of cases with or without congestive failure.

It would seem that, if emphysema of the so-called obstructive type, which is a relatively frequent disease, were obstructive in the sense that it always impedes the pulmonary circulation, there should be a far closer correlation between the degree and duration of emphysema on the one hand and evidence that the right ventricle has worked against resistance on the other. Most of the literature relative to the subject has failed to take into consideration the part which vascular changes (apart from capillary destruction) may have played in these cases in which hypertrophy of the right ventricle was found and was accompanied by congestive failure. One ventures to predict that when representative surveys of cases of emphysema are completed, results will show that emphysema of itself does not cause pulmonary hypertension, for, although the obliteration of capillaries is extensive in cases of advanced emphysema, it is extremely unlikely that it ever reaches a degree capable of exhausting the vascular reserve. In addition, evidence of failure of the right side of the heart, when it occurs, is usually owing to a second factor. This factor is either pulmonary arteriolar

sclerosis, left ventricular failure from any cause, or valvular heart disease (such as mitral disease) in itself not developed sufficiently to have produced symptoms earlier. Also, it must be recalled that emphysema most frequently occurs among individuals who have reached the decades when hypertensive disease and disease of the coronary artery are frequent.

It is more than of academic interest to determine whether pulmonary hypertension is present in cases of emphysema and pulmonary fibrosis or not, because it influences the prognosis very materially, and, in borderline cases, estimation of venous pressure may be necessary to decide this point. Patients who have uncomplicated emphysema, although they are forced to live a life of extreme limitation of activity, often give evidence of very little progression over several years, but as soon as evidence of pulmonary hypertension can be elicited, the course is likely to be progressively downhill, eventually with uncontrollable congestive failure.

Kyphoscoliosis. Kyphoscoliosis presents another interesting problem. The observation that the majority of "hunchbacks" ultimately succumb to heart failure often has been made. In 154 cases studied by Bachmann, eighty-seven gave evidence of hypertrophy of the right ventricle, twenty-seven of the left ventricle, and forty of both ventricles. Here, we are probably dealing with several factors rather than with any single mechanism. Thus, large portions of lung often are atelectatic and are associated with other regions of compensatory emphysema; chronic bronchitis is frequent and the mechanical effect of kinking of the great vessels unquestionably plays a part in producing a picture which tends to terminate in failure of the right side of the heart.

Arteriovenous shunts.—Any anatomic arrangement which permits of a shunt of blood from the arterial side into the pulmonary circulation may create increased pressure in the pulmonary circuit, depending on the volume of blood shunted.

Congenital arteriovenous shunts.

I. Patency of the ductus arteriosus. Because of the higher pressure in the aorta an extra quota of blood escapes through this channel into the pulmonary artery with each cardiac cycle.

II. Septal defects. In most cases of septal defects, the reflux of blood from the arterial to the venous side is not enough to cause any circulatory embarrassment unless a secondary factor supervenes which increases the arteriovenous shunt. A classic example of this type is so-called Lutembacher's disease consisting of a combination of mitral stenosis and a patulous foramen ovale. In such cases, extreme degrees of pulmonary hypertension with dilatation of the pulmonary artery to aneurysmal proportions may result.

III. Tetralogy of Fallot and other congenital anomalies associated with pulmonary stenosis result in a chronic cor pulmonale. Although an admixture of venous and arterial blood usually occurs in this group through imperfect septa, the pulmonic stenosis is the main etiologic factor concerned.

Acquired arteriovenous shunt. In rare instances a condition analogous to patency of the ductus botalli is created by the gradual rupture of an aortic aneurysm into the pulmonary artery. Such an event may be associated with the roentgenologic and electrocardiographic evidence of pulmonary hypertension and with a bruit simulating that caused by a patent ductus botalli.[5]

A Discussion of the Clinical Picture of Chronic Cor Pulmonale With Special Reference to Differential Diagnosis

In short, the clinical picture of chronic cor pulmonale is that of pulmonary hypertension plus the features contributed by the factor responsible for the pulmonary hypertension. In cases of so-called primary pulmonary arteriolar sclerosis, the distinct syndrome of pulmonary hypertension occurs without the presence of any such discoverable factor to obscure or to distort the clinical picture. There is usually a history of gradually increasing dyspnea as the obliterative process progresses. The resulting interference with ventilation gives rise to cyanosis, which also increases as the disease advances. The striking symptom, then, is dyspnea, which is prominent even in the absence of congestive heart failure and is out of all proportion to other evidence of congestive heart failure, when the right side of the heart does fail. In short, it is the dyspnea of interference with ventilation and this in itself immediately should suggest its pulmonary origin. It is a characteristic of all pulmonary diseases in which the function of oxygenation is limited.

By the time these patients present themselves

for examination, the secondary manifestations of pulmonary hypertension usually can be elicited. The individual often looks older than his chronologic age would imply, and this is accentuated by the cyanosis which is present. The striking auscultatory finding is an accentuated second pulmonic sound. The clinical evidence of a hypertrophic right ventricle is afforded by a systolic pulsation to the left of the sternum best elicited by firm palpation in this region. This is accounted for by the fact that, as the right ventricle becomes hypertrophic, it comes to form, more and more, the anterior surface of the heart and approximates the anterior wall of the thorax more closely. On auscultation, the lungs are likely to be clear even in the presence of congestive failure, because the obstruction is proximal to the alveolar system. It is only when the left side of the heart fails secondary to the effects of anoxemia that congestion of the bases of the lungs comes into the clinical picture.

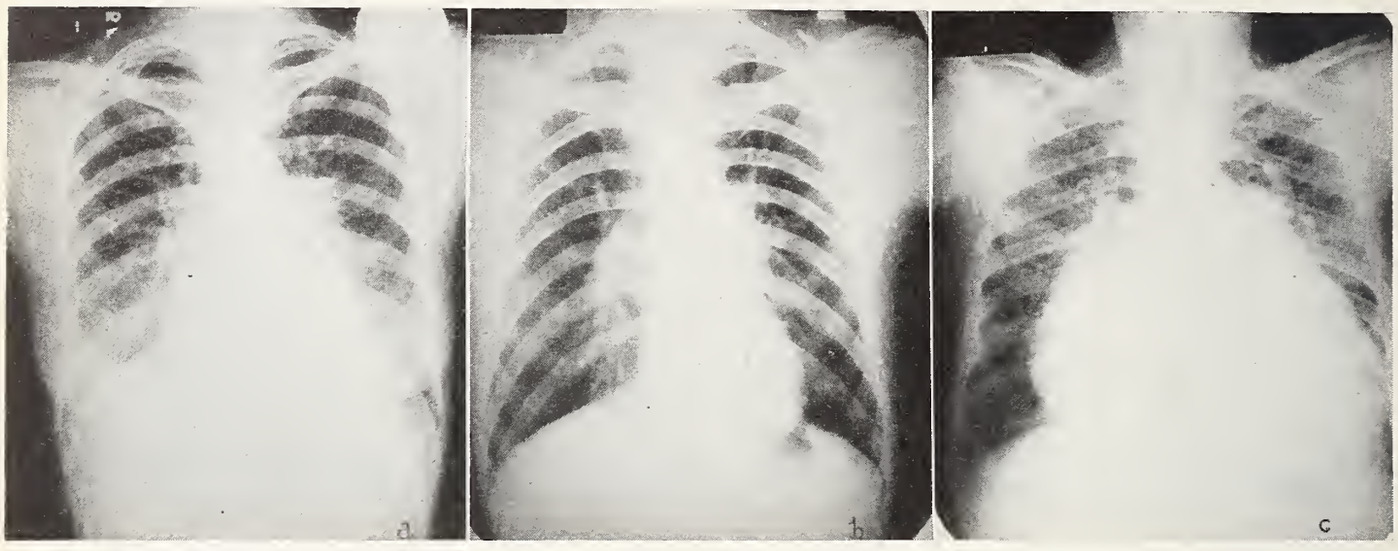

Fig. 3. Chronic cor pulmonale, representing three different mechanisms which can produce pulmonary hypertension: *a*, Obstruction beyond the pulmonary circuit by mitral stenosis (proved at necropsy); *b*, obstruction within the pulmonary circuit by pulmonary arteriolar sclerosis (proved at necropsy); *c*, arteriovenous shunt in widely patent foramen ovale (proved at necropsy). Points in common to all three types of chronic cor pulmonale are an aortic knob which is less prominent than normal, an enlarged conus shadow. There is enlargement through the auricles, especially the left auricle, except when the obstruction is within the pulmonary circuit when the left auricle is normal.

Confirmatory evidence is afforded by laboratory procedures. Roentgenologic examination reveals a prominent pulmonary conus, an enlarged right ventricle and auricle and unusually clear pulmonary fields. Pulsation of the vessels in the pulmonary hilus sometimes can be elicited. An important distinguishing feature is the absence of enlargement of the left auricle which distinguishes it from obstructions beyond the pulmonary circuit, as in cases of mitral stenosis (Fig. 3, *a, b, c*). Finally, the characteristic electrocardiographic pattern indicative of predominant right ventricular strain affords corroborative evidence (Fig. 4 *a, b*). This consists of right axis deviation which is usually definite and if changes in the T wave occur, they will consist of inversion in the second, third and fourth (standard) leads. There may be secondary polycythemia, the result of anoxemia.

With failure of the right side of the heart, venous congestion, hepatic enlargement, peripheral edema, ascites and increasing cyanosis are added to the picture and it is characteristic of this disease that, when congestive failure supervenes, the subsequent course is invariably rapidly downhill, a type of congestive failure unusually refractory to therapy.

This description holds essentially for pulmonary hypertension owing to any cause, the provoking disease, either in the pulmonary system or cardiovascular apparatus, adding its quota to the symptoms and findings described. Pulmonary hypertension secondary to diseases of the left side of the heart and to the congenital lesions enumerated needs no special comment because the corresponding clinical picture in each case bears hallmarks sufficiently well recognized to establish a diagnosis.[7]

The ability to distinguish between the various processes which cause pulmonary hypertension by obstructing various levels of the pulmonary

arterial tree depends on (1) a knowledge of the possible pathologic conditions which are capable of producing such obliterative vascular disease, (2) an understanding of the mechanism involved in each case, that is, the life history of the disease, and (3) a deliberate attempt to elicit evidence of pulmonary hypertension when diseases are encountered which are known to be capable of producing pulmonary hypertension. Because some of these diseases are likely to obscure the characteristic findings of pulmonary hypertension, valuable prognostic data may be overlooked unless a special effort is made to search for such evidence.

In short, these general principles are essentially the same as the methods employed in distinguishing between conditions which obstruct other hollow muscular viscera. The clinical course and the speed with which symptoms and signs develop often give a clue to the pathologic nature of the obstructing mechanism.

With special reference to the pulmonary circuit, we may lay down three principles which afford indirect evidence of the nature of the obstructing lesion: (1) The more proximal the obstruction, that is, the larger the vessels that are occluded, the more profound are the effects. (2) The more rapidly progressive the primary disease, the equally more rapid will the picture of failure of the right side of the heart supervene. Thus, in cases of carcinomatous lymphangitis, the course of failure of the right side of the heart is so much more rapid than in other cases of chronic cor pulmonale, that the term subacute cor pulmonale has aptly been applied to it. (3) Multiple factors which individually may place an inconsequential burden on the right ventricle, when acting together can become a serious threat to the integrity of the right side of the heart. Frequently, mitral stenosis of minimal degree that has been tolerated perfectly well terminates in congestive heart failure because a disturbance of ventilation such as that caused by emphysema, which in itself would not be incapacitating, is superimposed on it. The term Ayerza's disease purposely has been omitted from the discussion because this name has been linked with so many varied pathologic and clinical entities that it contributes neither etiologic nor differential diagnostic information.

Summary and Conclusions

Pulmonary hypertension is a secondary manifestation of a wide variety of conditions which exert their effects either by obstruction of the lesser circulation in or beyond the pulmonary circuit, or by shunts of arterial blood into the pulmonary circulation in certain cases of congenital cardiac anomalies.

The pulmonary circulation is endowed with a rich vascular reserve. Lesions obliterating the larger radicles of the pulmonary arterial tree curtail this reserve and produce pulmonary hypertension more readily than lesions affecting its more peripheral elements. By the same token, exhaustion of vascular reserve to the extent of causing pulmonary hypertension requires an extremely widespread, obliterative process, if the obstruction is at the capillary level. Thus, emphysema of itself seldom, if ever, causes pulmonary hypertension. Failure of the right side of the heart in the presence of capillary obstruc-

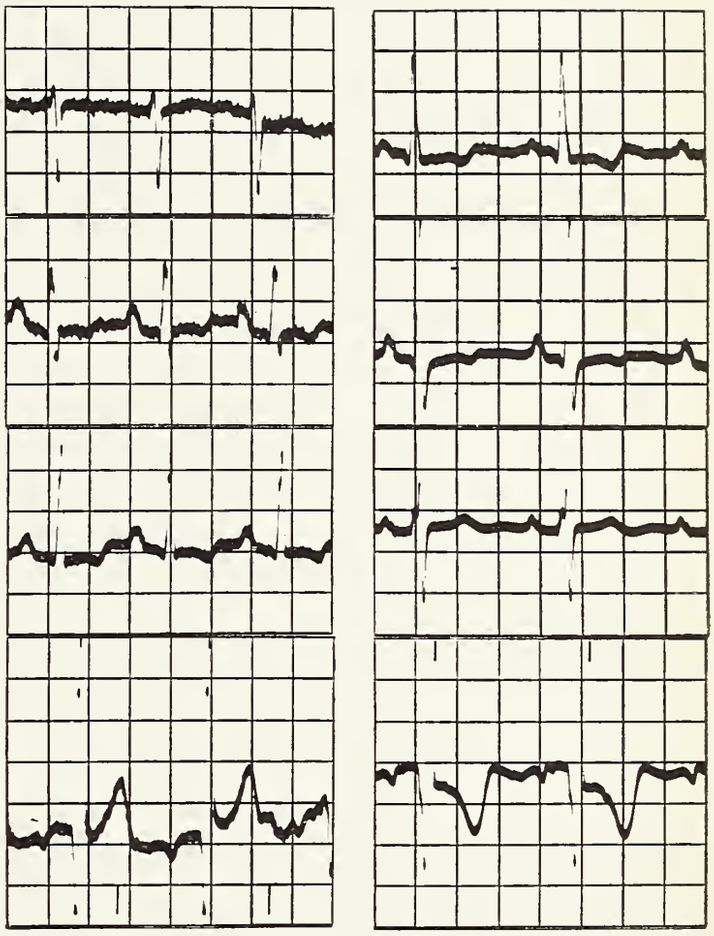

Fig. 4. Electrocardiograms: showing *a*, right ventricular strain resulting from pulmonary hypertension with right axis deviation, inversion of the T waves in leads II and III and a positive T wave in lead IV (Wolferth) and, for comparison, *b*, left ventricular strain with left axis deviation and inversion of the T waves in leads I and II. The fourth lead (Wolferth) is normal.

tion may be assumed to be associated with a second factor, either an associated obliterative process, proximal to the capillary level, or independent cardiovascular disease throwing an added burden of "back pressure" on the pulmonary circulation and on the right side of the heart. The increased incidence of both emphysema and degenerative cardiovascular disease after middle life must be kept in mind.

Irrespective of the mechanism responsible for its production, pulmonary hypertension is recognized by the secondary effects on the cardiorespiratory system, eventuating in right ventricular hypertrophy, characterized by accentuation of the second pulmonic sound, prominence of the pulmonary artery and conus roentgenologically and the electrocardiographic pattern of right ventricular strain. Absence of enlargement of the left auricle places the obstruction within the pulmonary circuit. Dyspnea is the prominent symptom and is usually progressive. When the obstruction is situated within the pulmonary circuit, dyspnea is caused by interference with ventilation and is usually prominent even in the absence of congestive features and out of all proportion to other evidence of congestive heart failure, when the right heart does fail. Under these circumstances, too, the pulmonary fields are likely to be unusually clear.

The final syndrome depends on the symptoms and signs that are contributed to this picture by the disease provoking the pulmonary hypertension. The differential diagnosis depends on a knowledge of the possible pathologic conditions capable of producing obliterative pulmonary vascular disease, a knowledge of the clinical behavior of these conditions, and on a deliberate attempt to elicit evidence of pulmonary hypertension when diseases are encountered which are known to be capable of producing pulmonary hypertension.

UTERINE CANCER*

ROLAND S. CRON, M.D., F.A.C.S.

Milwaukee, Wisconsin

EVIDENCE is gradually accumulating to prove that cancer in the United States is increasing. The cancer death rate, the number of deaths per 100,000, has increased from 63 per 100,000 in 1900 to 108 per 100,000 in 1935. A part of this increase may be related to the lengthened span of life and also to more accurate diagnosis, but most of it is due to its more frequent appearance. Its increase is viewed with alarm and by many it is considered our greatest menace. Further analysis of the situation shows that not over one out of every four treated cases of genital cancer in women remains cured for five years or more. This is not a very encouraging showing. It has not changed even with the lowered mortality resulting from the introduction of x-ray and radium therapy. Is it any wonder that, with the general instruction of the public, so many women have become cancer conscious and not a few developed a definite

*Presented at the eighty-fifth annual meeting of the Minnesota State Medical Association, Duluth, Minn., June 29, 1938.

phobia? Even so, there is no object in throwing up one's hands in horror, but, instead, let us do as Te Linde suggests, continue to hew away at the problem and thereby reduce the mortality little by little. Cancer of the cervix is the most common variety of uterine cancer, occurring about eight times to each fundal cancer. It is a disease of middle life, but has no respect for age periods. It has been seen in the first and last decades of life but its greatest incidence is in the years immediately preceding and including the menopause, the menopausal period being assumed to occur between the ages of forty and forty-five. The writer, however, has been impressed with the frequency of the disease during the second and third decades. He is of the opinion it is making its appearance at earlier ages. Cancer of the corpus in contrast is distinctly a disease of the menopause and postmenopausal period.

Etiology

Formerly, we considered cervical cancer a rarity in the woman who had never experienced pregnancy. This is not true. Cervical and especially fundal carcinoma are frequently found in the nonparous uterus. Cervical lacerations and erosions have never been proven to be precursors of cancer, but a lacerated, eroded and discharging cervix is not only a definite focus of infection but also a menace. Cautery, repair or excision of such a lesion will act as a prophylaxis against cancer and make detection of any malignant lesion in the future much easier. Vaginal pessaries when worn for correction of retroversion or prolapse of the uterus do not cause cancer. For hygienic reasons, they should be removed and cleansed at frequent intervals. It is also wise, at that time, to inspect the vagina and cervix and to treat any lesion present. That so-called chronic irritation of the cervix is not the cause of cancer is well borne out by the infrequency of its incidence in prolapse of the uterus. In a study of 200 cases of uterine prolapse not a single cancer of the cervix was found.

Cancer appearing in the cervix following subtotal hysterectomy is frequently the result of a faulty diagnosis before or at the time of operation. It is often present in the cervix at that time and is either not recognized by the operator because of his inability to do so, or not diagnosed because of his negligence to visualize and study the cervix. The argument that such errors could be rectified by performing total instead of subtotal hysterectomies is an unsound one. True, such a procedure will cure early cervical cancer and prevent the subsequent development of one, but it will also increase the operative mortality. There is no question but that, in the hands of operators doing the large majority of hysterectomies in this country, the supravaginal operation is the safer and simpler of the two. Also the reduction in morbidity, injured intestines, bladder, and ureters will compensate many times over for any increase in cervical stump cancer. And finally an eroded, infected, degenerated or lacerated cervix can be treated very satisfactorily through the vagina.

Uterine fibromyomata and strictures of the uterine canal are occasionally associated with corporal cancer. Oesterlin and the author found that 20 per cent of fundal cancers were associated with myomata. In the majority of cases, it was coincidental, but in at least one uterus a calcified nodule impinged upon a malignant area directly opposite to it. Strictures by damming back infected secretions may also be factors in the etiology of cancer.

Evidence is accumulating to show that heredity is a factor in the appearance of cancer. There is a greater incidence in brother and sister relationship than in husband and wife. Cancer families are a definite entity. Experimentally, Maud Slye has proved that cancer susceptibility in rodents is hereditary. The least one should do is to speculate on the possibility that this is a recessive Mendelian characteristic.

Hormones have been suggested as the cause of cancer. There is an amazing similarity in the chemical formula of estrogenic and carcinogenic substance. One has only to switch a few radicals of the chemical formula of estrin and one has the stimulus necessary for carcinoma. It has also been observed that hyperplasia of the endometrium during the menopause is associated with the excretion of estrin in the urine. Novak states that a postmenopausal endometrium subjected to persistent estrogenic stimulation is predisposed to adenocarcinoma. Such observations have opened an entire new lead in cancer investigation. It may not be a mistake to bring up the problem of the indiscriminate use of the endocrines in the treatment of the many ailments of women. The long continued substitutional

administration of any glandular product may result in atrophy of the organ treated.

Pathology

Cervical cancer is most commonly epidermoid. Early in its metamorphosis it appears as a circumscribed, easily bleeding, slightly elevated lesion. Only very occasionally it is seen or recognized at this stage. Later, it is an excavated ulcer or a cauliflower-like mass. These three types of lesions make up 90 to 95 per cent of all cervical cancerous lesions. The other 5 to 10 per cent are adenocarcinomata. They arise in the canal and cannot be distinguished macroscopically from epidermoid cancer. They are almost always far advanced when diagnosed, due to the fact that the vaginal portion of the cervix remains intact, while the growth extends into the neighboring structures.

A few pertinent facts in regard to the grading of malignant tumors are worthy of presentation. Broders, in 1920, was the first to correlate the different microscopic pictures of similar cancers with their clinical course. Thus, he was able to divide, histologically, all cancers into four groups or grades. This also covered the clinical outcome from those which could be cured to those which were hopeless. The principle of grading is based upon an estimation of the ratio of mature to immature cells within the tumor. In Broders' classification, a grade one carcinoma contains 0 to 25 per cent immature or undifferentiated cells. This is the least malignant lesion. A grade two cancer has 25 to 50 per cent immature cells; a a grade three 50 to 75 per cent immature cells and a grade four 75 to 100 per cent immature cells. This last is the most malignant lesion.

A study of the incidence of cervical cancer has shown that very few if any can be classified as grade one where most of the cells are mature or differentiated; that only 15 per cent are of grade two; and that 85 per cent are grade three and four, where the cells are for the most part immature or undifferentiated. The chief characteristic of these immature cells is that the chromatin of the nucleus is deep staining and granular and stands out most prominently. Mitosis is very active. The nucleolus is also proportionately greatly increased in size. Fundal cancer can be graded in a similar way, but there are many more that can be classified as grades one and two than is the case in cervical cancer. Correspondingly, more than 60 per cent of fundal cancers remain cured five years or longer.

Ewing has divided corporal cancer into adenoma malignum and adenocarcinoma. The incidence of the two are about equal but the percentage of three-year cures is about ninety-three for adenoma malignum against thirty-nine for adenocarcinoma. Fundal cancer, in either case, has a much better prognosis than cervical cancer. It remains confined to its site of origin much longer than does cervical cancer.

A correlation of the grade of cervical cancer and end-results of treatment shows that, independent of the stage or advancement of the disease, grade two cancers when treated by x-ray, radium, surgery or a combination of any of the three have resulted in 53 per cent of five-year cures. On the surface this result appears encouraging, but on further analysis one finds that only 15 per cent of cervical cancers are grade two cancers. Grade three cancers, when treated, result in 21 per cent cures and grade four in 9 per cent five-year cures and since 85 per cent of all cervical cancers are in these two groups the average of five-year cures has never advanced much beyond 25 per cent.

Diagnosis

The early diagnosis of uterine cancer depends upon two factors. First, the consulting of the physician by the patient. Even in spite of the immense amount of publicity and propaganda that has been carried on during the past years many women, suspecting or having cancer, still prefer to remain in ignorance of their condition. Then, they report to their physician only long after their doom has been sealed. Stovall, in an editorial, summarized the situation as follows: "This is due to the public's fear of cancer. They are aware of the fatality of the disease commonly recognized as cancer and cancer is commonly recognized as a late process. The public thinks of the doctor in connection with critical illness only. The way to change this attitude is to give them the basic facts on which to diagnose early cancer. The thoughtful consideration of this will lead them to the acceptance of the advice that early cancer is curable."

The part the physician plays. He must be able to recognize the disease in its incipiency or, at least, before it has involved adjacent structures or metastasized. To accomplish this he must

obtain a thorough and complete history. The earliest symptom of uterine and cervical cancer is bleeding. It may be only a show or it may be profuse. It may occur before, during, or after the menopause. Its outstanding characteristic is that it frequently follows trauma such as coitus, douching, or instrumentation. Bleeding after the menopause in over 50 per cent of cases is due to cancer. It may be associated with a watery and foul discharge, but this is usually a complaint of a more advanced stage. Pain is a late symptom.

Every woman consulting a physician for a health examination or because of any illness should have a gynecological examination. This examination should consist in not only bimanual palpation (single finger) but also visualization of the cervix. The examination is then completed only after tissue from any questionable area has been removed for microscopic study. Thus, one may be able to diagnose incipient and very early cervical cancer. No gynecological examination is complete without rectal palpation. The number of anal and rectal cancers casually diagnosed by this procedure is surprising. More important is the assistance it affords the examiner in determining the extent of involvement of the broad and sacro-uterine ligaments and rectum by an inflammatory reaction or carcinoma. Occasionally, it is the only means of ascertaining the size and mobility of the uterus and adnexa. It is always a great help in evaluating one of these problems.

Hinselman and others by magnification of the cervix have described the characteristics of early cancerous lesions. These are: (1) leukoplakic patches; (2) slightly elevated prominent pale areas with uneven surfaces and richly supplied with blood vessels; (3) a slightly irregular area with a tendency to bleed readily and having appearance of an erosion; (4) very small ulcerations, shallow with slightly elevated margins and friability detected on palpation.

Schiller uses the iodine test to aid in the detection of early cancer. The cervix is painted with Gram's iodine solution. Cancerous and all other tissue deficient in glycogen will not take the stain, while the rest of the epithelium takes on a chestnut brown. Unfortunately, inflammatory areas, erosions, nabothian cysts, hornified areas and cervical canal epithelium fail to take the stain.

Whether one uses the colposcope, Schiller's test or the naked eye the final diagnosis must be accomplished by removing tissue and examining it under the microscope. When obtaining tissue it is wise to remove a generous piece including suspected cancerous as well as healthy tissue. One may obtain this with the knife followed by cauterization of the cut surface or by the use of surgical diathermy. There is very little if any danger of disseminating cancer by curettage or biopsy. Squeezing or manipulating a growth is much more likely to produce metastases. Endocervical and fundal carcinoma is diagnosed by examination of tissue obtained by curettage.

Treatment

The greatest opportunity in treatment of cervical cancer still lies in the field of prophylaxis. Thorough eradication of benign cervical pathology by whatever means indicated, be it cauterization, conization, plastic repair, amputation or total hysterectomy, will prevent the development of cervical cancer. The author does not know of a single case of malignancy developing in a healthy cervix. Infection and inflammation are more important predisposing causes of cancer than are lacerations and scars. It is even conceivable that prophylactic treatment may cure very early unrecognized cancer.

Epidermoid cervical cancer is most successfully treated by x-ray and radium. Experience has proven that preliminary high voltage deep therapy x-ray followed by topical and intracavitary radiation produces the best end-results. Initial x-ray exposures through six ports with cross firing brings about amazing shrinkage of the tumor, reduction in the amount of infection and sealing of the lymphatics. It is also more effective if administered before the cancer becomes radioresistant from the influence of the radium.

Radium can be administered either in one or two doses or frequent small ones. In either case, it should be well distributed and applied where it will accomplish the most good. It should be carefully screened and the adjacent structures well protected. This is especially true when using massive doses.

Fundal and early cervical adenocarcinoma is most successfully treated by complete extirpation of the uterus, followed by roentgen-ray therapy.

When surgery is not feasible, treatment with x-ray and radium has afforded good results.

Injuries to bladder, bowel, ureters and small intestines have resulted from x-ray and especially radium therapy. Many times, these injuries do not appear until later in the disease or after an apparent cure. Swelling of the broad ligaments, the result of local inflammatory reactions, produce difficulty with elimination. Temporary or permanent bowel obstructions and interference with ureteral function are common. Occasionally, rectal and ureteral dilatations are indicated. Bladder injuries are distressing. Various fistulas are usually the result of malignant tissue destruction but many times the radium therapy is unjustly blamed. Cancer fistulas are generally irreparable.

Prognosis

The grade of the malignancy of uterine cancer is by far the most important factor to consider in prognosis. Tumors of low grade mean slow growth, late metastases, less radiosensitivity and a greater percentage of cures. On the other hand, tumors of high grade have a faster growth, earlier metastases, more radiosensitivity but a shorter length of life. Other factors being equal, the more immature the cell in the tumor (higher grade), the more radiosensitive is that tumor. It is this type of lesion that one should treat most intensively, first with x-ray, and then radium.

Of course, there are other factors which influence the outcome of treatment. The younger the patient the more virulent the disease. Epidermoid cancer of similar grade in a woman of sixty is not as serious a lesion as if it were present in a woman of thirty. The local extent of the lesion is likewise of great importance. Cancers involving only the portio vaginalis of the cervix or the endometrium of the fundus in adenocarcinoma are lesions most amenable to treatment. Metastases and extension, of course, are most important determining factors. Finally, it is up to the clinician to combine his knowledge of all of these factors and after that to give a fairly accurate prognosis.

SULFANILAMIDE IN UROLOGY*

EDWARD N. COOK, M.D., and HENRY A. BUCHTEL, M.D.

Rochester, Minnesota

SULFANILAMIDE (p-amino-benzene-sulfanilamide) is a new drug which is proving its value in the treatment of many and varied diseases. A certain skepticism has accompanied its introduction, and rightly so; but when it is used under the careful and diligent supervision of the physician, a minimum of serious complications has developed.

The antecedent of sulfanilamide was discovered in 1908, but it remained for Domagk, in 1935, to revive interest in it. He was able to demonstrate its therapeutic activity and in a very short while many other investigators had corroborated his work with the various forms of this drug.

Sulfanilamide has been tried in all fields of medicine, and urology is no exception. During the past five years, the treatment of infections of the urinary tract has been taken from its place in the hit or miss file and assigned to a respectable position in the scientific therapy of disease. We have learned the value of frequent and careful bacteriologic investigation in every case of infection of the urinary tract. Depending on the results of Gram's stain and culture of the urine, we have planned our treatment, and sulfanilamide is a welcome addition to our armamentarium. The importance of this drug to the urologist is becoming well known.

Mode of Administration and Dosage

When sulfanilamide is given to man, it is practically entirely eliminated in the urine in a free state and in a conjugated form, as paraacetyl amino benzene sulfanilamide. When given orally, the rate of absorption of the drug varies somewhat in different cases; two or three days usually are required to establish equilibrium between the amount ingested and the amount excreted. Following the taking of this drug, concentrations which are but slightly lower than

*From the Section on Urology, The Mayo Clinic, Rochester, Minnesota.

those in the blood occur in the prostatic secretion, pleural and peritoneal effusions, and spinal fluid.

The dosage of this drug in urologic conditions varies and is greatly different from the dosage in its general use. When treating infections of the urinary tract, we feel it advisable to begin with the maximal dosage in order to build up an adequate concentration of the drug in the body as quickly as possible. What this initial dosage will be depends on the age of the patient, the general condition of the patient, and the nature of the disease. Clinically, in a series of more than 600 cases, we have observed that the elderly patient rarely will tolerate a dosage greater than 40 grains (2.59 gm.) daily. Fortunately this dosage is frequently sufficient to sterilize the urine, and an increase is not necessary. In cases in which the patients are debilitated, the drug must always be given with care. In certain cases in which it is not advisable to give this dose, even smaller doses have produced some benefit, and it is wise to limit the dose. In cases in which the patients are young and strong, daily doses of 60 to 75 grains (4 to 5 gm.) of sulfanilamide are well tolerated and are advised. Our usual procedure is to give 60 grains (4 gm.) each day for two or three days and then reduce the dose to 40 grains (2.59 gm.) daily; the latter dose is maintained for the entire period of treatment, which usually lasts eight to fourteen days. Administration of the drug should be stopped at the end of this time, regardless of the condition of the urine. If sterilization of the urine has not taken place, a similar course of therapy is repeated in ten to fourteen days. When treating gonorrhea, we usually use a dose of 75 grains (5 gm.) daily for two or three days, then 60 grains (4 gm.) daily for a similar period, and then 40 grains (2.59 gm.) daily until a period of fourteen days has elapsed since the beginning of treatment. A second course of treatment may be necessary after a rest of ten to fourteen days without medication.

Clinically, the effectiveness of this drug is attended with many of the limitations which attended the use of the ketogenic diet or the administration of mandelic acid in the treatment of infections of the urinary tract. Nevertheless, the drug is of great value in a few cases in which these latter forms of medication failed entirely.

We will consider the use of sulfanilamide in a variety of urologic conditions.

Uncomplicated Infections

When the causative organism is any one of the bacilli usually found in the urinary tract, the use of this drug is attended with great success. Even in cases in which organisms of the genus Proteus are found, the results have been good, as we have not had to contend with the factor of pH, as we did with mandelic acid.

In cases of infection of the urinary tract in which there is no complicating factor, such as obstruction to the flow of urine, stone, tumor, or cicatricial deformity of the renal pelvis and calices, sulfanilamide is of great value. Eighty-two patients who had uncomplicated infection of the urinary tract and who were treated at The Mayo Clinic were followed in great detail. In seventy of these cases a bacillus was the causative organism, and in twelve cases a coccus was found. In sixty-four cases in which the infection was caused by a bacillus, the urine became sterile while the patients were on sulfanilamide therapy. In two cases there was definite improvement, and in four cases no benefit was noted. Of the twelve patients who had infection caused by a coccus, nine were definitely cured and three did not obtain benefit at all.

Complicated Infections

When a bacillary infection of the urinary tract is associated with chronic prostatitis, our experience in the past has been that the efficacy of mandelic acid or the ketogenic diet was definitely reduced. Fortunately, this is not equally true when sulfanilamide is used. In our earlier work, we were able to show that the concentration of sulfanilamide in the prostatic secretion is only slightly less than that reported in the blood of patients taking the drug. We feel that this is the explanation for the increased efficiency of this drug in cases in which bacilluria is associated with marked chronic prostatitis. In almost all instances the same bacillus can be isolated in pure culture from the prostatic secretion. We feel that prostatic massage is clearly indicated in conjunction with the administration of sulfanilamide and have carried out the procedure in all our cases. There were ninety-eight cases of this type in our series: in sixty-two of these cases the infection was caused by bacilli and in thirty-

six cases it was caused by cocci. In the cases of bacillary infections, fifty-two patients had sterile urine at the end of the period of treatment and obtained a very marked improvement in the degree of prostatitis. Eight patients were improved, but the urine was not sterile, and in two cases there was no improvement. In the thirty-six cases of coccal infection, eighteen patients experienced very marked relief and the urine became sterile, eight were improved, but ten were not benefited by the administration of sulfanilamide. In more than half of the cases in which the patients were not benefited, the organism was the Streptococcus fæcalis, which, we knew, experimentally and clinically, would not usually respond to sulfanilamide therapy. More striking than the improvement in the urine or in the symptoms was the improvement of the prostatitis in this group of cases. Under the usual prostatic treatment, which consists of massage, heat, and urethral irrigations, it is very unusual to see an appreciable change in the number of pus cells in the prostatic secretion in less than six to eight weeks. When this local regimen was combined with the administration of sulfanilamide by mouth, a very definite change in the cell count was frequently noticed in seven to ten days. However, in the group of cases of nonspecific prostatitis in which there was no bacteriuria, sulfanilamide has had little or no effect on the degree of prostatitis.

Renal infections without any complicating factor, such as stone, obstruction, or cicatricial deformity, respond very well to this drug. There were eighteen cases of this type, and in sixteen cases the urine was rendered sterile. When the pyelonephritis is associated with any of the complications mentioned, the results are not nearly so good. In fifty-eight of the eighty-two cases of complicated renal infection, bacilli were found in the urine. In twenty-two of these cases the urine became sterile, and a similar number of patients noted improvement; in fourteen cases there was no change. Of twenty-four patients who had a coccal infection, only four had sterile urine after treatment, and ten did not improve. The same number, however, did experience relief of symptoms with some improvement in the urine, although the cultures remained positive.

In cases of prostatism, sulfanilamide must be given with care because of the age of the patients. When the drug is administered as a preliminary measure, before any surgical procedure is directed to the relief of obstruction at the neck of the bladder, it rarely will produce a sterile urine. In a considerable percentage of cases, some improvement may be noted, but there usually is not much benefit. However, the drug is worthy of trial when the urine is very cloudy. Gaudin, Zide and Thompson have carefully studied the value of giving this drug postoperatively to patients who have undergone a transurethral prostatic resection. As a general rule the drug was usually poorly tolerated by the patients. However, there seemed to be less infection in the urines of these patients at the time of their dismissal from the hospital than there was in the urines of a group of patients who were not taking the drug. Again, the raw healing surface of the prostatic bed will preclude sterilization of the urine, and it seems advisable to postpone administration of sulfanilamide or any other strenuous attempts to eradicate the infection until healing has taken place. This seems to correspond with our experience with mandelic acid or the ketogenic diet, as previously reported.

Gonorrhea

In cases of gonorrhea our results have been just as good. From time immemorial the medical profession has sought some drug which, when given by mouth, would be destructive to the Neisseria gonorrhoeæ. Following the work of Dees and Colston, many workers have used this drug in treating gonorrhea with variable success. In our rather small series of cases, we discontinued all local treatment when giving the drug, in order to ascertain its true worth. However, we insisted on abstinence from alcohol and any form of sexual excitement. In twenty-one cases the patients were males and in twelve they were females. All but two of the males responded nicely to the drug. In some of these cases a second course of sulfanilamide was necessary before the cultures became negative, and each one had a follow-up course of the drug two weeks after the cultures became negative. Eight of the females obtained negative cultures within one month after the treatment was started, but in the other four cases repeated courses of sulfanilamide were ineffectual and fever therapy was resorted to. In one case this failed, and it was finally decided to give the patient large doses of sulfanilamide. When the concentration of the

drug in the blood was high, the patient was given a ten-hour treatment in the Kettering hypertherm and diathermy was applied to the pelvis for five hours during the period of elevated temperature. Following this procedure, the cultures became negative and have remained so since treatment was stopped seven months ago. Unquestionably, in this case we were dealing with a very resistant strain of the Neisseria gonorrhoeæ.

In a second group of thirty-eight cases of gonorrhea observed in the city dispensary, there were thirty males and eight females. Seven males had clear urine, no urethral discharge, and negative smears in twelve days. Fifteen of the patients showed very definite improvement during the first course of sulfanilamide, but the urine was still hazy and the smears were positive. In these cases a second course of sulfanilamide, however, produced negative smears and negative cultures in an additional twelve days. In eight cases there was little or no change in the symptoms or in the objective findings after the first course of treatment. We then used local treatment which consisted of instillations of mild silver protein (5 per cent solution of mild protein silver and 5 per cent solution of neo-silvol) or 1:3000 solution of merthiolate. Later, the patients again were given sulfanilamide and in all instances the symptoms were relieved and the smears became negative. In this group of cases the shortest period of treatment was two months and the longest was three months. All of these patients were seen at intervals of one week for a month after the smears and cultures became negative.

Of the eight females, two did not complete the treatment. In four cases the cultures became negative within three weeks after administration of the drug was started, and the cultures remained negative for two months, at which time the patients were dismissed. In two cases local treatment was instituted and the administration of sulfanilamide was repeated. In these cases all cultures were negative at the end of an additional eight weeks.

In regard to complications, one man had a swollen, tender right epididymis at the time of admission; within twenty-four hours after administration of the drug was started, the swelling had decreased a fourth, the tenderness was practically gone, and the urethral discharge had stopped completely. Another patient had a swollen, reddened left epididymis; this resulted in fluctuation, which necessitated incision and drainage in spite of sulfanilamide and fever treatment. We have seen a few cases of gonorrheal arthritis, and the results have been variable. If there is not a very marked decrease in the pain and swelling of the gonorrheal joint within three to six days after starting sulfanilamide treatment, we believe the patient should be subjected to fever treatment, as this method of therapy has been of the greatest value in such cases.

Complications

In reviewing our cases we have noted few untoward results with sulfanilamide therapy. Approximately 8 to 10 per cent of our patients have been unable to take the drug for any appreciable period. Some of these will have to stop taking it after the first few doses and others will have to discontinue taking it later because of marked cyanosis or skin reactions. We do not believe that tinnitus, headache, nausea, or a mild cyanosis necessitates discontinuing administration of the drug, but we do feel that these symptoms should demand close observation of the patient. If the physician will insist on frequent, regular visits of the patient, we feel certain that any probably serious reaction can be averted. Prolonged or intensive administration of sulfanilamide may produce methemoglobinemia or sulphemoglobinemia. The latter condition is of serious consequence and must be watched for. Granulocytopenia and acute hemolytic anemia have also been reported as occurring after sulfanilamide administration. If the drug is used extensively, it is well to examine the blood microscopically for evidence of destruction of the corpuscles.

Comment

Within a relatively short period, sulfanilamide has proved itself of inestimable value in the treatment of infections of the urinary tract. The drug is more efficacious in the treatment of bacillary infections than it is in the treatment of coccal infections. It has little or no effect on the Streptococcus fæcalis. The Neisseria gonorrhoeæ is definitely killed by the drug in the majority of instances.

The limitations of its use in treating infections of the urinary tract are well recognized, and

when complications of infection occur, such as stone, tumor, or obstruction, the effectiveness of the drug is greatly reduced. The use of the drug is not without danger. At least 10 per cent of patients will not tolerate the drug, and this is particularly true of elderly patients. Definite toxic signs do appear and must be watched for. The drug should always be administered under the diligent supervision of the physician, who should note any untoward reaction. This will practically always avert any serious reaction to the administration of sulfanilamide.

THE PRESENT STATUS OF GASTROSCOPY*

NORMAN GIERE, M.D.

Minneapolis, Minnesota

MUCH has been written concerning the procedure of gastroscopy since the introduction of the flexible instrument in 1932 by Schindler. Most of the literature has concerned itself with the phase of gastroscopy in which the worker was especially interested. Since so much was promised at its inception by the enthusiasts of the procedure whereas by the skeptics it was thought to be little more than an ultra refinement in gastro-intestinal diagnostic procedures, it might be well at this time to take stock as to what the experience of the various workers in this field has been, and thus to gain some conception of its present status in medicine.

Schindler[21] has said that in the field of gastritis gastroscopy will find its greatest usefulness. This statement is undoubtedly true for the reason that gastroscopic examination alone can accurately diagnose this condition in the usual case. Much work has been done by roentgenologists in attempting to diagnose gastritis by relief method,[3,16] and in the hands of experienced and critical examiners certain cases may be correctly diagnosed. It is safe to say, however, that the present consensus amongst radiologists is in agreement with Berg, who stated at the fifth international congress of radiology in Chicago that even careful study of the mucosal relief would often fail to indicate the presence of chronic gastritis. This disease entity has previously been a very indefinite thing. Acute gastritis was clearly shown by the famous observations which Beaumont made on his Canadian, St. Martin, through an open gastric fistula. Chronic gastritis, however, could not be shown to exist in such an objective and dramatic way and thus after a period of great enthusiasm the disease disappeared from routine diagnosis. Many pathologists[5] at various times thought they had found sections of gastric mucosa which demonstrated gastritic changes. In most instances, however, it was found to have been due to post mortem changes. Knud Faber was the first to inject a ten per cent solution of formalin directly into the abdominal cavity immediately following death, thus fixing the tissues and establishing the histological entity of gastritis. We are indebted to pathological specimen study and the gastroscope for not only definitely establishing the disease as an entity, but also for allowing us to conclude that it is very probably the most frequent cause of gastric disturbance.[6,7,17] Gutzeit[6] has stated that in his clinic gastritis was observed twelve times as frequently as was gastric ulcer and three times as frequently as was duodenal ulcer. Henning[15] stated that because of the frequency of gastritis he believes no diagnostic investigation of the stomach to be complete without gastroscopic examination. It is not the purpose of this paper to discuss the pathology of gastritis, but merely to suggest that experience has borne out the predictions as to the value of gastroscopy in diagnosing this condition. Observation of gastritis is important not only in order to manage the existing condition but because of the possible complications. If we are to agree with the gastritic theory as advocated by Hurst,[8] Konjetzny[10] and Knud Faber[5] as to the etiology of ulcer it is to be expected that by treatment of the gastritis many potential cases of ulcer might be prevented, and in cases where the ulcer process has already begun that treatment will be instituted earlier. If we believe with Schindler[20] that ulcer originates from a mucosal hemorrhage

*From the Department of Surgery, University of Minnesota College of Medicine.

either as a result of stasis due to protracted irritation of the vasomotor nerves or of traumatic origin, it can still be said that observation of these early mucosal changes will allow earlier and thus more satisfactory control of gastric ulcer. Hurst[9] and Konjetzny,[11] among others, also believe that atrophic gastritis generally precedes the development of gastric carcinoma. Hurst[9] has shown that anacidity is present not only in 75 per cent of gastric cancer as a result of chronic gastritis, but that it was present for years before the carcinoma developed. Thus, it seems reasonable to suppose that periodic observations of cases of atrophic gastritis may result in earlier diagnosis of gastric carcinoma. Recently, two cases were reported from the Mayo Clinic in which carcinoma developed within fifteen and four months respectively from a hypertrophic gastritis, which had been examined microscopically from biopsy taken at the first operation and which was seen to have been free from carcinoma at that time. In the report of these cases,[4] the statement is made: "The conception that chronic gastritis is the soil in which cancer develops in a large percentage of cases, if finally accepted, will influence greatly the methods used in the prophylaxis and early diagnosis of cancer."

In any branch of medicine it is usually conceded that the most satisfactory and exact means of studying the progress of treatment of a gross lesion is by direct inspection; this applies as definitely to gastric lesions as to those of other parts of the body. It may be added that since there is the possibility of a malignant change developing from a benign mucosal lesion the importance of direct inspection may be even greater than in some other cases. As a diagnostic procedure, gastroscopy is probably not as valuable in ulcer cases as is x-ray.[4] Both have their advantages and each can demonstrate the ulcer in certain cases where the other fails. In those cases where the lesions are visualized by gastroscopy we find the procedure to be of value in following their therapeutic management. Both Gutzeit[6] and Schindler[14] are of the opinion that clinically and roentgenologically the ulcer is apparently healed at a time that gastroscopic examination can clearly demonstrate its existence. Gutzeit believes this to be of great importance in the correct management of gastric ulcer and in the prevention of recurrence. Schindler[19] has stated that complete epithelialization of ulcer can be determined only by gastroscopy and that this completion may require as long as two months after refined x-ray compression has failed to visualize any abnormality.

At the international congress of gastro-enterology held in Paris this past September the question for consideration was early diagnosis of gastric carcinoma. Many speakers were enthusiastic about the value of gastroscopic examination in this respect. It must be stated, however, that practically all these statements were based on clinical impressions rather than on controlled study. Schindler states:[18] "There is much reason for thinking that a differential diagnosis between a benign and a malignant ulcer can be made much more easily by gastroscopy than by any other procedure." Other gastroscopists are not so sure that a correct differential diagnosis can be made in such a high percentage of cases (Moutier, Rodgers, Henning, Friedrich).[15] It is true that the circulating blood seems to facilitate the differentiation between benign and malignant ulcers. The floor of the carcinomatous ulcer is not the usual dull yellowish gray of the benign ulcer, but is rather dark brown or violet in color.[7] The edge is generally ragged and irregular instead of giving the sharp punched out appearance of the benign ulcer.[18] In addition, the transition from the ulcer to normal tissue is more gradual in cases of malignancy than is usual in benign ulcers. A controlled series of cases for differential diagnosis was studied by Schindler and the author in 1936 with the conclusion that in this particular series gastroscopic examination gave more correct and detailed information concerning differential diagnosis than did roentgen examination.[22] More controlled work must be done to determine the exact value of gastroscopy in differential diagnosis of benign and malignant lesions, but that it is of value can at this time be safely stated.

Up to the present time exploratory surgery has been very frequently carried out in cases of advanced gastric carcinoma. The end-results have, of course, been very poor. This fact not only makes surgical mortality figures for cancer cases as a whole unreasonably high, but helps to instill in the mind of the layman the attitude that surgery in all cases of gastric cancer is hopeless. It is reasonable to believe that all surgeons would welcome a method which would give the

needed information without the operative risk. It is possible that gastroscopy will to a large extent fill this need. Nine case of gastric carcinoma were studied in which the question of operability arose. The accuracy of gastroscopic examination in these cases as to demonstrating the operability of the lesion was not only found to be greater than by x-ray, but was, in fact, correct in every instance.[22] Inoperability of a gastric tumor may become evident by gastroscopy;[1,12,22] it may be shown that the tumor is not sharply defined and that the infiltration extends too high to allow even a radical operation.[10] Certainly, if these cases of obvious inoperability as shown by gastroscopy could be saved from exploratory operation, it is reasonable to suppose that the surgical mortality from gastric carcinoma would be lowered, which in turn might convince medical men and laymen that the prognosis of an early carcinoma of the stomach is a very different thing from that of an advanced case. They would understand that early cancer may be cured by surgery whereas it is not even attempted in cases of advanced cancer. It is possible that this would result not only in more operations in cases of gastric carcinoma, but particularly in a higher percentage of early cases in which definite cure is most likely to be brought about. By way of bringing about this end the following simple suggestions have been made:[22]

a. Patients over thirty-five years of age who have anorexia and loss of weight should be examined roentgenographically and gastroscopically.

b. All patients suffering from a gastric carcinoma, which is not diffusely infiltrating but is sharply limited, should be advised to undergo operation regardless of the location of the neoplasm, unless it is at the extreme cardiac end. On the other hand, a diffusely infiltrating tumor should be operated on only if it is small and if it is strictly confined to the pyloric region.

c. Exploratory laparotomy should be done only in those cases in which gastroscopy cannot definitely decide the operability of the lesion.

In addition to the above instances in which gastroscopy has proved its value, we have the further consideration of its potential value in investigative work of stomach diseases in general. Since it allows direct visual study we may hope to arrive at an understanding of disease processes which will ultimately prove to be of great practical value. In this connection we may speak of gastritis, which lamentably has no specific treatment. It is conceivable that the objective study which gastroscopy permits may disclose an understanding of the condition which may eventuate in control of the disease. Another great field for gastroscopic investigation is found in the study of cases which have undergone gastric surgery. The importance of this work lies in the attempt to determine the cause of the poor clinical results which frequently follow. In a study of the condition, it was found that the four principal morphological changes which may cause postoperative trouble following gastroenterostomy or gastric resection were the following:[22]

1. Recurrent or gastrojejunal ulcer. This condition was long thought to be the only complication in the postoperative stomach.

2. Chronic gastritis. This is now thought to be by far the most frequent cause.

3. Erosions and irritation caused by silk sutures remaining from operation and which have cut through the mucous membrane.

4. Carcinoma which develops at the stoma —very rare. Since gastroscopists[2,6,12,13] agree that chronic gastritis is a frequent and important cause of postoperative trouble, gastroscopy becomes important not only in the differential diagnosis but again in allowing an objective study of the condition.[2] The gastritis causes at least as much discomfort as recurrent ulcers and may even cause massive hemorrhages.[7,10,22] Some interesting findings have already come to light in this connection. In a series of thirty cases, four were found which did not present gastric changes, and in each case it was noted that the artificial stoma had developed a pylorus-like activity in contrast to the patent nonactive stomas of those cases showing gastritis.[22] It may be supposed that this pylorus-like functioning of the postoperative stoma may be a factor in inhibiting the development of this condition; it may be thought that the intestinal juices flowing into the stomach through this patent opening is in some way responsible. It is not known what the surgeon can do in resections to favor the development of this pylorus-like activity of the new stoma, but Schindler believes that in

cases of gastroenterostomy those carried out on the posterior wall near the greater curvature close to the pylorus are most likely to show this adaptability. More work is being done on this important question at the present time.

It seems then that on the basis of the experience of gastroscopists since the introduction of the flexible instrument the following points may be fairly stated by way of determining the present status of the procedure:

1. Gastroscopy offers a practical and safe objective method of gastric examination.
2. Gastroscopy offers the best method available in determining the presence of gastritis or other mucosal changes of the stomach.
3. Gastroscopy allows direct visual control of therapeutic progress during treatment of gastric lesions.
4. Gastroscopy gives valuable information in differential diagnosis of benign and malignant lesions.
5. Gastroscopy is of value in determining operability of gastric carcinoma, thereby making less frequent the necessity for exploratory surgery.
6. Gastroscopy has great potential value in investigative work of stomach diseases in general.

TUMORS OF THE LARYNX*

FREDERICK A. FIGI, M.D.

Rochester, Minnesota

TUMORS of the larynx constitute some of the most interesting and at the same time the most serious of the pathologic conditions that affect this structure. A number of different types of benign and malignant neoplasms occur. Some of these are met with frequently, and accordingly are of great clinical importance. Others are so rare that a laryngologist of even wide experience is not likely to see more than one or two during many years of practice. Early recognition and proper treatment of these growths is extremely important, since the likelihood of cure, particularly in cases of malignant tumor, is directly dependent on these two factors.

The possibility that a tumor of the larynx is present must be ruled out in every case in which chronic hoarseness, labored breathing, persistent cough, difficulty in swallowing or any symptoms referable to the lower part of the throat are encountered. These tumors may occur at any period of life but are most common in middle age. At times they are present at, or shortly following, birth. With few exceptions, those which occur among patients less than twenty years of age are benign. Malignant neoplasms at times are met with in the first and second decades, however. Since malignant disease is much more prevalent during the degenerative period of life than earlier, an increasing proportion of malignant tumors of the larynx is encountered with advancing age. Males of all ages are much more frequently affected by both benign and malignant tumors of the larynx than are females. The most

*From the Division on Laryngology, Oral and Plastic Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the meeting of the North Dakota Academy of Ophthalmology and Otolaryngology, Bismarck, North Dakota, May 17, 1938.

common benign laryngeal growths are, in the order of their frequency, papillomas, myxomas, cysts, inflammatory masses, epithelial hyperplasia and leukoplakia, angiomas and amyloid tumors. Fibromas, chondromas and xanthomas occur rarely. Among the malignant neoplasms, carcinomas (epitheliomas) are by far the most common. Sarcomas, hemangio-endotheliomas and adenocarcinomas comprise a small proportion of such growths.

Benign Tumors

The symptoms of benign tumors of the larynx depend on the situation, attachment and size of the growth. These neoplasms may be present for years and become large without producing symptoms sufficiently severe to cause the individual to seek medical aid. Many of them are, in fact, discovered in the course of routine examination of the throat while patients are undergoing a general physical examination. This is particularly true of the cysts which develop on the anterior aspect of the epiglottis. If these originate on the free border of the vocal cords, however, symptoms are noted promptly. Discomfort in the larynx, effort in speaking, hoarseness, dyspnea, cough and complete aphonia are commonly present. A small, sessile growth may impair the voice more than a large, pedunculated one, especially if it is situated on the anterior portion of a vocal cord. Repeated efforts at clearing the throat at times are made. Attacks of glottic spasm and a sensation as of a foreign body being present in the throat may be experienced. Severe paroxysmal dyspnea may be produced by a pedunculated neoplasm, but more frequently the respiratory difficulty associated with benign tumors in this situation is constant.

The diagnosis of benign tumor of the larynx usually can be made from inspection of the tumor, together with consideration of the history and the age of the patient. When there is any doubt concerning the nature of the mass, biopsy should be done.

Treatment and prognosis in these cases depend largely on the nature of the tumor and its extent, and will be considered individually for the different groups.

Papillomas of the larynx are usually multiple. They are the most common of the benign neoplasms which occur in this situation, and may be met with at any period of life from infancy to old age. They may even be congenital. If individuals are of middle or advanced age the growths may be malignant. They may occur in any portion of the larynx but are most commonly situated on the true or false vocal cords and in the subglottic region. Frequently they extend well down to, or beyond, the bifurcation of the trachea. This extension may occur while they are still present in the larynx, or after the larynx has been entirely freed of the growths. At times they fill the upper portion of the larynx and a large part of the hypopharynx, extending well up on the base of the tongue and pharyngeal wall, so that they are visible on looking directly back into the mouth.

Papillomas may appear as single, but usually as multiple, warty growths, often presenting as grape-like clusters. At times they form an almost flat, verrucous surface, again a large, irregular cluster of a whitish, pinkish or reddish color. They may be fibrous or very friable, and they range from 1 or 2 mm. to 2 or 3 cm. in diameter. Usually they grow slowly, but following incomplete removal or if an inflammatory process is present, growth may be very rapid. There is no associated pain and no invasion of the surface to which they are attached. They frequently produce respiratory obstruction and necessitate tracheotomy. Recurrence is likely following removal, especially if individuals are young. At times papillomas will become engrafted on traumatized portions of the larynx or pharynx and they may become malignant, even when the patients are small children. I have seen epithelioma develop on the basis of recurring papillomas in the larynx of a girl five years of age and, in several other cases, they developed in the first and second decades of life.

Removal of papillomas and electrocoagulation of their attachment by means of direct, indirect or suspension laryngoscopy offers the best chance of cure. This latter procedure is usually most satisfactory as it permits of a very good view and the surgeon is enabled to use both hands. Treatment by means of radium tubes held directly in contact with the growth in the larynx, or by means of externally placed radium packs, formerly was used a great deal, but has been discarded by most laryngologists because of the danger of perichondritis. Roentgen therapy is in more general favor at present, although it does not offer the possibility of cure that is offered by

electrocoagulation. While multiple papillomas at times disappear following infectious diseases, subsequent to a single external application of radium or after tracheotomy, more frequently they are extremely persistent and require repeated removal and electrocoagulation, especially if patients are young. With persistence and patience the prognosis is usually good, however.

Myxomas of the larynx are encountered frequently in our experience at The Mayo Clinic, next in frequency to papillomas. The patients usually are adults and the tumors most commonly are attached by a broad base to the free border or upper surface of the anterior portion of the vocal cords, where they exert the greatest interference with voice production. In most cases a tumor of this sort presents as a single, small, discrete nodule, measuring only 3 or 4 mm. in diameter, but the tumor may be diffuse and widespread, involving the entire length of both vocal cords and rarely the ventricular bands as well. The color is usually grayish, pink or deep red. At times the nodule is hemorrhagic and its appearance very strikingly resembles that of an angioma. Microscopic examination of the majority of these tumors discloses some inflammatory reaction in the myxomatous tissue.

Treatment of myxomas consists in removal and electrocoagulation of the base by means of either direct or indirect laryngoscopy. There is very little tendency for the growths to recur, providing they are cleanly removed. If involvement is diffuse, it is difficult entirely to eradicate the growth.

Cysts of the larynx are usually smooth, translucent tumors situated on the anterior aspect of the epiglottis, but they may occur on the ventricular bands, the aryepiglottic folds, the pharyngeal surface of the larynx, or, rarely, on the vocal cords. They most often have broad, sessile attachments and the color may be yellow, grayish, pink or red. At times they strikingly resemble lipomas. Their size varies from 1 to 4 cm. in diameter. While usually single, they may be multiple.

Unless cysts are of sufficient size to produce symptoms, treatment is often not necessary. Situated as they commonly are, in the vallecula, and attached to the anterior aspect of the epiglottis, they rarely cause trouble. When removal is necessary, the wall of the cyst should be excised and the base electrocoagulated.

Fibromas are said by Thomson to be next to papillomas in order of frequency of benign laryngeal tumors. This has not been true in our experience at The Mayo Clinic. Fibromas are encountered chiefly among adults and are usually attached to the middle or anterior portion of the vocal cords; however, they may spring from any part of the larynx. In color they vary from whitish or grayish to pink or even deep red. While they usually are firm, smooth, round, sessile growths, they may be soft, pedunculated and, at times, nodular. Tortuous blood vessels often stand out prominently on the surface of the growth. The diameter ranges from a few millimeters to 3 or 4 cm. We have encountered fibromas which had broad sessile attachments covering almost the entire laryngeal aspect of the epiglottis. In one such case the tumor completely concealed the glottis and produced moderate respiratory obstruction so that preliminary tracheotomy was necessary prior to electrocoagulation, using laryngeal suspension.

Singers' nodes should be mentioned in this connection for they are frequently assumed to be neoplasms. Actually they are merely the chief feature of a form of chronic laryngitis. The nodules are usually bilateral, localized portions of hypertrophic epithelium, but they may be fibrous. They are situated at the junction of the anterior and middle thirds of the vocal cords and are caused by faulty voice production. Often they develop promptly following strain of the voice, and they may disappear spontaneously in the course of some months with rest of the voice. They frequently require removal, however.

True angiomas of the larynx are rare; a total of only fifty-five cases had been reported up to 1919. These included forty-seven hemangiomas and eight lymphangiomas. They may occur primarily in the larynx but more often they are associated with similar conditions about the face, mouth or upper air passages. Cavernous hemangioma is the most frequent type. It usually involves the true or false cords and appears as a smooth, soft, compressible, dark bluish or purplish mass.

Unless angiomas are producing severe symptoms, no treatment other than irradiation should be carried out because of the danger of hemorrhage and secondary infection.

Amyloid tumors of the larynx are rarely encountered. They may occur either as part of gen-

eral amyloidosis in which other organs of the body are involved, or as a local condition. They are not true neoplasms. In the larynx the condition may exist as a diffuse subepithelial amyloid infiltration, localized amyloidosis with tumor formation or amyloid degeneration of a preëxisting tumor. The clinical picture of the condition is rarely sufficiently characteristic to permit of positive recognition without microscopic confirmation. The vocal cords, ventricular bands and subglottic region are most often involved.

Treatment of amyloid tumors consists in removal and irradiation if the involved portion is sufficiently localized, otherwise radium or roentgen therapy alone is employed.

Chondromas are among the more unusual of the benign tumors of the larynx. During the period of fourteen years preceding 1932, only six such tumors were seen at The Mayo Clinic, while approximately 600 malignant neoplasms were encountered. These six cases increased to seventy-seven, the total number reported up to that time. Most of these cartilaginous tumors arise from the cricoid and thyroid cartilages and more frequently from their inner aspects than elsewhere. A few originate from the epiglottis and arytenoid cartilages. Laryngoscopic examination of tumors of this type which arise within the larynx usually reveals a smooth, sessile mass covered with normal mucous membrane in which the blood vessels stand out prominently. This feature is especially striking, and of itself is strongly suggestive of chondroma. The tumor is hard on palpation and may be pedunculated, although it is more often sessile. Mechanical interference with the mobility of one or both vocal cords is commonly present.

The diagnosis of chondromas of the larynx at times can be made from the history, together with the physical findings and roentgenographic demonstration of the tumor; microscopic examination of the tissue, however, as a rule is necessary for confirmation.

Treatment of chondromas depends on the situation and size of the growth, the character of its attachment to the laryngeal cartilages and its activity. Surgical removal is, of course, necessary, but the usual benign character of these tumors justifies decided conservatism. Laryngectomy is indicated only in case the growth is so extensive that its complete removal would leave a nonfunctioning, collapsed larynx. Prompt recurrence is likely to follow incomplete removal.

Tumors of the thyroid gland are at times present in the larynx and are attributable to abnormal distribution of thyroid tissue. They grow slowly, are covered with normal mucous membrane and usually appear very vascular. Attempt at removal is, as a rule, inadvisable unless they are producing severe symptoms, for they may contain the only thyroid tissue that the patient possesses.

So-called prolapse of the laryngeal ventricle probably is not an eversion of the ventricle of Morgagni, as the name implies. The smooth, pinkish, fleshy tumor indicated by this term apparently results from hypertrophy of a portion of the mucous membrane of the ventricle. Electrocoagulation of the mass, using either direct or indirect laryngoscopy, is the most satisfactory form of treatment.

Certain infectious processes at times produce tumor-like masses in the larynx which must be distinguished from true neoplasms. Most important among these are tuberculosis, syphilis, blastomycosis, leprosy and rhinoscleroma. Solitary tuberculoma and gumma of the larynx at times strikingly simulate neoplasms. As these conditions are not neoplasms, however, they need not be considered here.

Malignant Tumors

Malignant tumors of the larynx alone present a big subject for discussion and only a brief consideration of them can be given here. These neoplasms are, with few exceptions, squamous-cell carcinomas and a discussion of these latter growths accordingly will suffice for the entire group.

Carcinoma of the larynx, while not a common disease, is encountered more frequently than are benign tumors in this situation. This, together with its seriousness, makes carcinoma of great clinical importance. An average of approximately sixty patients who had this condition have been examined at The Mayo Clinic in each of the past twelve years. The disease is about ten times as common among males as among females. The majority of these tumors affect patients between the ages of forty and seventy years and most of them occur when the patients are between fifty and sixty years of age. The disease, however, not infrequently is encountered in examination of patients who have not

reached forty or who have passed seventy years of age. I have carried out laryngectomy for squamous-cell epithelioma of the larynx which affected two boys, aged sixteen and nineteen years, respectively, and have met with the condition in several other instances in which the patients were in the second, or even in the first, decade of life.

Carcinoma of the larynx most commonly originates on, or in close proximity to, the vocal cords, usually on the upper surface of the anterior two-thirds of these structures. Extension, then, as a rule takes place along the length of the cord, and as this is at times a slow, gradual process, the lesion may remain operable for a considerable time, possibly for several years.

These tumors generally have been classified as intrinsic and extrinsic. The intrinsic tumors consist of those lesions which spring from the vocal cords, ventricular bands, ventricles, interarytenoid region and subglottic region. The extrinsic growths are those which develop about the epiglottis, aryepiglottic folds, arytenoid cartilages, pyriform sinuses and postcricoid region. In our experience it has seemed more logical to designate tumors of the epiglottis, aryepiglottic folds and arytenoid cartilages as "supraglottic" lesions, and those of the pyriform fossæ and postcricoid region as "laryngopharyngeal" or "hypopharyngeal" lesions. The supraglottic growths, with the exception of those which spring from the arytenoid cartilages, are less active, metastasize later, and offer a much better prognosis than do tumors of the laryngopharynx. In addition, surgical considerations in the two groups are vastly different. The majority of supraglottic growths spring from the epiglottis, especially its posterior aspect, and secondarily involve the aryepiglottic folds. They are usually fungating rather than infiltrating and commonly appear as cauliflower-like masses. Tumors of the laryngopharynx are prone to metastasize very early; this is in marked contrast to most of those tumors which originate within the larynx.

The earliest and most common symptom of carcinoma of the larynx, in the majority of cases, is hoarseness. Change in the voice of an adult, which persists for more than a few weeks, particularly if the patient is a man, always should arouse suspicion. Progression is gradual and usually painless until the lesion is well advanced.

The symptoms of advanced laryngeal carcinoma, that is, dyspnea, dysphagia, pain and hemorrhage, vary in their time of onset, depending largely on the situation and activity of the growth.

To an experienced laryngologist the picture of laryngeal carcinoma is recognizable on clinical examination in the majority of cases. Recent treatment or an acute inflammatory process will alter the picture to such an extent as to cause considerable difficulty and delay in diagnosis. In any event, even though the diagnosis appears obvious on clinical examination, it should always be confirmed by biopsy before treatment is initiated. Failure to obtain such confirmation has resulted in needless removal of more than one larynx.

The prognosis in carcinoma of the larynx depends on the situation, extent and activity of the growth, as well as on the thoroughness of treatment and the general condition of the patient. A fatal termination is inevitable without treatment and, as a rule, takes place in from one to three years. Death is usually the result of suffocation, dysphagia, hemorrhage, cachexia, sepsis or some intercurrent complication. Early intrinsic carcinoma of the larynx offers a very favorable prognosis. Lesions on the posterior aspect of the epiglottis and on the aryepiglottic folds also offer a satisfactory outlook.

Generally speaking, carcinoma of the larynx should be dealt with by means of radical operation, as only through an open operation can the majority of laryngeal carcinomas be clearly visualized. Lesions situated in the supraglottic portion of the larynx, especially those which spring from the epiglottis or the aryepiglottic folds, and which are commonly of an inactive type, often can be treated satisfactorily by suspension laryngoscopy; the lesion is electrocoagulated directly through the mouth. Pharyngotomy is at times necessary in this group of cases because of the extent, situation and activity of the growth. Preliminary tracheotomy may be required also. Thyrotomy, or laryngofissure, is the most satisfactory procedure for dealing with early, intrinsic carcinoma of the larynx. Laryngologists, however, hold widely divergent views concerning the usefulness of this procedure. One group, of which Sir St. Clair Thomson is the leading proponent, recommends laryngofissure "so long as the disease appears limited to the soft parts lining one-half of the larynx." The other group,

headed by the late Dr. Mackenty, has taken a much more radical stand, holding that the operation is indicated only for "middle third cord growths involving only the surface of the vocal or ventricular bands circumscribed and small in extent and of slow growth"; in all other cases, laryngectomy is advised. My own inclination is to reserve thyrotomy for cases of laryngeal carcinoma in which the tumor is inactive and not fixed, or, if active, the tumor must be in a very early stage and well localized.

Thyrotomy is decidedly preferable to laryngectomy if its use is consistent with safety, for it leaves the patient with a very useful and often an almost normal voice and does not alter the upper air passages. Thyrotomy consists in dividing the thyroid cartilage, usually in the median line, although when the lesion extends into the anterior commissure it is safer to open the larynx a little to the opposite side. The growth is then excised and the open wound thoroughly electrocoagulated. A cannula usually is introduced into the trachea at the same time because of the possibility of respiratory obstruction resulting from the local reaction following the operation. In properly selected cases laryngofissure offers an excellent chance of curing the disease. Of thirty-four patients whom we were able to trace following this operation at the clinic, twenty-eight (82.3 per cent) were living and well five years later.

When the malignant process involves both sides of the larynx or extends onto the arytenoid cartilage on one or both sides, especially if it is active or if there is fixation, complete removal of the larynx alone offers a reasonable chance of controlling the disease. Even though many of these tumors are highly malignant, laryngectomy will result in cure in a high percentage of cases, providing the disease has not spread beyond the larynx. In cases in which perforation or metastasis of a highly malignant tumor has occurred, especially if the patient is young, the prognosis is so poor that operation rarely is indicated.

Laryngectomy gradually has been perfected during the years until at present the mortality following the operation is remarkably low. Tapia, of Spain, a few years ago reported a series of 106 consecutive cases in which laryngectomy was performed without an operative death. At The Mayo Clinic the longest series without a fatality was sixty cases.

As is true of most of the other major operations on the upper part of the respiratory tract, laryngectomy is best carried out under cervical block anesthesia because of the lessened danger of pulmonary complications as compared with general anesthesia. We routinely perform preliminary tracheotomy, as we feel that this renders the operation much safer than it is when the preliminary procedure is omitted. While laryngectomy permanently deprives the patient of his normal voice, satisfactory speech is possible in all cases with the use of one of the several mechanical contrivances now on the market. With one of these, most of the patients suffer comparatively little handicap and are able to resume their original calling even though it entails considerable speaking. Moreover, with speech training many patients develop satisfactory speech by swallowing air and utilizing the pharyngeal muscles for production of the voice as the air is regurgitated. The exposed tracheal opening causes comparatively little inconvenience, and patients who have such an opening are no more subject to infections of the respiratory tract than are normal individuals. The marked mental depression following laryngectomy, described in some of the older textbooks, rarely has been seen at the clinic.

The end-results with regard to control of the carcinoma are very gratifying. Seventy-three patients who were subjected to laryngectomy were traced, and forty-one (56.1 per cent) of them were found to be alive and well after five years.

Radium and roentgen rays often are of considerable value as supplementary measures in the treatment of malignant tumors of the larynx. They rarely should be used to the exclusion of other measures, however, in the treatment of malignant laryngeal lesions that can be removed surgically. In recent years the Coutard fractional dosage method of roentgen therapy has been used a good deal in the treatment of advanced laryngeal carcinomas. Encouraging primary results have been obtained in some of the cases, but the results do not warrant substitution of this form of therapy for surgical measures in cases of operable carcinoma of the larynx.

FUTURE AIMS OF THE HOSPITAL LIBRARY*

GORDON R. KAMMAN, M.D., F.A.C.P.

Instructor in Neurology and Psychiatry, University of Minnesota

Saint Paul, Minnesota

IF there is any phase of the care of the sick in which our European contemporaries surpass us, it is in providing our hospitalized sick with suitable reading material and properly supervised reading programs. In this respect some of the Europeans are years in advance of us. One of the reasons probably is that here the medical profession is not fully aware of the therapeutic possibilities of reading when directed and supervised by one who is especially trained in that field of endeavor. Possibly the hospital administrators or even the librarians themselves are equally responsible for lack of interest in this field; but, regardless of on whom the responsibility lies, effort along this front several years ago would have resulted in significant advances. Proof of this assertion lies in the fact that in the comparatively brief time that the subject has been receiving attention in this country, great progress has been made in the field of hospital librarianship.

The first formal get-together of persons in the American Hospital Association and affiliated groups interested in hospital libraries was held in Philadelphia in September, 1934. At this meeting it was pointed out that the hospital library is a very important accessory service in the complete and rounded out care of the patient. It was further pointed out that in the minds of hospital people there was not the proper appreciation of the importance of this fact. I was honored by a request to address this meeting. In preparing my address I found that practicing physicians as a whole had even less appreciation of hospital library service than did anybody else. At the meeting there were papers on various aspects of hospital librarianship and in every one of them the need of hospital librarians and of trained librarians to supervise them was stressed. It also was pointed out that there exists a fundamental difference between public and hospital libraries. In the former, scientific accuracy and literary merit are the criteria of a book. In the latter, therapeutic effectiveness is the only criterion of a book. Thus a book may be a literary masterpiece and yet have little therapeutic value. It may even be harmful to the patient. By the same token, a book may be very inferior as a literary work, yet it may be very effective from a therapeutic standpoint.

The next meeting was held at the time of the American Hospital Association meeting at St. Louis, in September, 1935. There the meeting was much better attended than at Philadelphia, and in the transactions of the American Hospital Association for that year the discussion on hospital libraries covers ten more printed pages than the one at Philadelphia. There it was pointed out that in twenty-five States of the Union, there were 386 hospitals with library service, but that there were only forty-two trained librarians. At this meeting also, the necessity was mentioned for a scientific study on the reading habits of patients. Dr. Magnus Peterson, who is now superintendent of the State Hospital at Willmar, Minnesota, gave a very fine paper indicating how it is possible to establish reading curves for patients and in this way obtain insight into some of their psychodynamics, and also to evaluate the results of planned reading programs on controlled groups of patients.

By September, 1936, when the American Hospital Association met in Cleveland, the hospital library movement had grown, and this meeting was attended the best of all. By this time, under the stimulation and guidance of Miss Perrie Jones and her very able committee, the Quarterly Book List had been issued and been put on a subscription basis. Then there were 134 paid subscriptions, and I am informed by Miss Jones that there are now more than 250 paid subscriptions, a gain of nearly 100 per cent in less than two years. This is a very healthy sign. In this list are published each quarter fifty annotated titles each of fiction and nonfiction, plus scores of titles of inexpensive reprints, specially illustrated material, and a few entries for professional reading. At this Cleve-

*Delivered before Association of Hospital and Medical Librarians, Minnesota Hospital Association, Minneapolis, Minnesota, May 20, 1938.

land meeting, which was the last one I attended, it was also pointed out that somebody was necessary to establish contact between books and patients. This meant a trained librarian.

In this same year the American College of Surgeons recognized the hospital library movement, and at its meeting that year in Philadelphia there was a formal round table discussion of hospital libraries. This was led by Miss Perrie Jones.

The present situation here in Minnesota is, I believe, a healthy one. Here the Minnesota Association of Hospital, Medical and Institution Librarians is doing pioneer work. It is engaged in what is the first step of any new investigation. It is gathering together all of the available factual data having to do with hospital libraries in this state. This kind of survey is the first requisite of any intelligent approach to the consideration of a new project. One of the many things discovered is the fact that we have in this state 3,148 hospital patients who are without library service of any kind. My guess is that the incidence of patients who are not so supplied in other states is much higher. In order to supply the demand for trained hospital librarians, the Division of Library Instruction at the University of Minnesota now offers a course for training hospital librarians. To show the demand for people so trained, one need only to be reminded of the fact that every student taking this course last year (the first one given) was offered a position as hospital librarian within a very short time after she had finished the course. I feel that the ground work is being well laid here in Minnesota, and now a few remarks might be pertinent concerning the future aims of the hospital library.

The first question to be considered is: "Should each hospital have its own library?" I believe that the answer is: "Yes," unless as in Saint Paul, Minneapolis and other large towns in the state, the public or municipal library is able to furnish adequate hospital library service. Even then it would be preferable for the larger hospitals to have their own libraries independent of the municipal library. This is especially true in the case of the hospital for tuberculous patients. We all know how reluctant people are to send books to tuberculous people, and we also know how difficult it is to induce anybody to use a book which is known to have been in the hands of somebody suffering from tuberculosis. Furthermore, a hospital owning its own library has many advantages.

1. The Reading Room.—If a hospital owns its own books and keeps them in its own library, it is more likely that there will be a reading room set aside for the use of the patients. This promotes a community spirit among the patients and is conducive to an atmosphere of goodwill and of cheerfulness. I might add in passing that it is my firm conviction that the reading room should be kept absolutely separate from the room for occupational therapy, the room for social service, and the room for physiotherapy. Each of these activities is an important adjunct to the treatment of the hospitalized sick, and each one is an integral part of the hospital. However, while they are part of an integral whole, they should be separate departments within the hospital itself.

2. Equipment.—If each hospital had its own library, it could also have its own distinctive book carts and other equipment. This equipment could be designed to serve the particular class of patients cared for in each particular hospital. Every physician knows the importance of having meals served in an attractive manner on trays tastily arranged. By the same token it is necessary in order to interest patients in reading, to serve the books in an attractive manner. The book carts should be designed to excite the curiosity and to please the taste of the type of patient cared for in the hospital under consideration.

3. Planning.—If the hospital owns its own library, it is easier for the librarian to work out a reading program for each patient. She knows exactly what books are available and where they are. She can correlate that patient's reading with various other projects in the treatment program and can always calculate what books will be available to any particular patient at an approximate time. Furthermore, she can organize programs of group reading and of project reading. Group discussions, research reading, and reference reading are much more easily planned if the library is part of the hospital itself instead of being a separate institution.

4. A Resident Librarian.—If the hospital owned the library, the librarian could be a resident member of the hospital staff. She could live in the hospital, be available at all times for

consultation with the attending or the resident staff, and also supervise evening group reading activities.

This brings us to the second question: "What should be the relationship between the hospital librarian and the rest of the hospital staff?" In my opinion, the hospital librarian should be considered the same as any other therapist. The librarian should be a consultant in the same sense as the occupational therapist, the physiotherapist, or the medical social service worker. We frequently consult with the dietitian about the patient's diet, so why not consult with the librarian about the patient's reading? I like the idea of considering the hospital librarian as an expert in psychologic dietetics. The librarian should be known as the bibliotherapist. She should consult with the attending staff whenever possible, and in certain hospitals and under certain conditions sit in on staff conferences. This, of course, will vary with the kind of hospital and the particular set-up under consideration.

Everything that I have discussed thus far will necessitate launching a very active educational program among physicians. Dr. MacEachern says that doctors are very quick to take up anything once they are convinced that it is for the good of the patient. Doctors must be taught the importance of professional supervision of the reading programs of their patients. They must be taught the difference between recreational, educational and therapeutic reading, and the value and place for each one of them. They must be taught that it requires experience, training and skill to fit the right book to the right patient. They must be taught that a skilled bibliotherapist can help materially in reducing the patient's morbidity and in shortening his convalescense in a great number and variety of illnesses. This means that at medical meetings more papers should be read dealing with this phase of the care of the sick. Any well rounded plan for the care of the sick must contain bibliotherapy as well as occupational therapy, physiotherapy, dietotherapy and medical social service.

I may be visionary and very speculative on this subject, but I can conceive of a plan by which the patient could be furnished with a program of supervised reading even after he leaves the hospital. The day may come when the bibliotherapist will make regular visits to the patient's home after he has left the hospital, and, like the social service worker, aid in his rehabilitation. I am firmly convinced that today bibliotherapy is in the same stage of development as medical social service was a generation ago. As medical social service has grown into a major adjunct to the care of the sick, so will bibliotherapy grow in a like manner.

MELANOSIS COLI*

LOUIS A. BUIE, M.D.

Rochester, Minnesota

MELANOSIS coli of Virchow cannot be considered a pathologic disorder but one in which a form of pigment is deposited, chiefly in the tunica propria of the mucous membrane of the colon, as a result of some disturbance of its function, accompanied by slowing of its activity, development of a condition commonly classified as constipation or colonic stasis and the laxative habit. The condition may occur also in the colons of individuals who harbor obstructive lesions.

Although melanosis coli has been recognized since it was first described by Cruveilhier a full century ago, all studies which have been devoted to the subject had been based on postmortem investigations until Bockus, Willard and Bauk published their report in 1933. It remained, therefore, for these investigators to provide the first and, as far as I know, the only comprehensive record of the condition as it appears in vivo and of its clinical interpretation.

Virchow's description in 1847 followed that of Cruveilhier, and the report of C. T. Williams, twenty years later, was next in order. According to Stewart and Hickman, a description of a case of melanosis coli, in which the patient was a lead worker who died of chronic Bright's disease, was provided by G. N. Pitt in 1891, and Rolleston reported a similar case the following year. Noth-

*From the Section on Proctology, The Mayo Clinic, Rochester, Minnesota.

ing further of interest appeared until 1930, when Pick and Brahn furnished the first account of the morbid anatomy of melanosis coli. Stewart and Hickman, when referring to the study made by Henschen and Bergstrand in 1913, stated that they showed that "while gross examples of the disease are comparatively rare, microscopic pigmentation of the colon is of frequent occurrence."

Various ideas as to the source of the pigment and its method of entry into the mucous membrane of the colon have been advanced, but thus far there has been little agreement on these subjects, and it is doubtful if plausible explanations have been advanced. Some believe that the pigment is hematogenous; some maintain that metals such as mercury and lead are the causes, while others adhere to the conception that the deposit is melanin and occurs as a result of the action of a tyrosinase-like ferment on aromatic products of degradation of protein.

Incidence

Most estimates of the incidence of this condition are based on postmortem examinations and are, therefore, unsatisfactory as far as clinical value is concerned. Bockus, Willard and Bauk provided the only exception to this and I employ their figures for comparison with those which I have obtained from a study of similar cases at The Mayo Clinic. They found an incidence of 2.7 per cent in examination of 960 routine "office" patients. Among those patients who gave definite evidence of "colon stasis," they found that the incidence was 5.1 per cent. They also found that the incidence by age was practically the same as that observed among individuals who complained of constipation. Of their patients, 88 per cent were females. Of the patients who were subjected to proctoscopic examination at the clinic, from 1925 to 1934, inclusive, about half complained of constipation. About 25 per cent of those who were constipated were able to control their sluggish colonic function by dietetic measures or by taking only an occasional laxative, so that for comparison with the series of Bockus, Willard and Bauk, there are left 75 per cent of the constipated patients, and these represent, to a certain degree, the type of patient which Bockus, Willard and Bauk studied. In this group we found 571 patients with melanotic deposits in the lining of the colon, or an incidence of about 3.5 per cent, which compares favorably with 5.1 per cent found by Bockus, Willard and Bauk in examination of those patients who evidently had the more severe form of constipation termed "colon stasis." The incidence of melanosis coli in our entire series of patients was 1.3 per cent, which strikingly corroborates the estimate of 1.0 per cent furnished by Lockhart-Mummery (quoted by Bockus, Willard and Bauk). The age incidence in our study was also found to parallel the age at which constipation appears, and 74.1 per cent of our patients were between the ages of thirty and sixty years. The distribution by sex also agreed with that of individuals who suffer with constipation; 381 (66.7 per cent) of the patients who had melanosis coli were females, and 190 (33.3 per cent) were males.

Gross and Microscopic Appearance

One who sees this melanotic deposit in the rectal mucosa for the first time may be confused as to its nature, but once it has been observed and identified, there does not seem to be any reason why such difficulty should be experienced again. There is rather wide variation in the intensity of the color but its appearance otherwise, and its arrangement, are unmistakable and if the mucosal surface is rubbed with a cotton applicator, inflammatory or ulcerous change, with which the condition may be confused, will not be found. If inflammatory reaction is present, the pinkish stain of serosanguineous exudate will appear on the cotton applicator when the diseased mucous membrane is traumatized. If there is no such stain, the condition may be melanotic. The pigment may be light brown, dark brown or black. It may be scattered in the mucous membrane, or it may leave no part of the lining of the bowel uninvolved; it is rare for the condition to extend beyond the confines of the colon. On closer scrutiny it will be observed that the coloring is not solid but is divided by linear, yellowish markings, into small segments, usually several millimeters in diameter (scarcely ever as large as a centimeter). According to Pick and Brahn, the yellow striations are owing to the vascular pattern of the superficial blood vessels of the colonic wall, an idea which accords with Pope's description of the vascular arrangement of the colonic mucosa, and the lymph follicles account for the spots of yellow at the angles of the yellow lines. The segments may be square or irregularly polyhedral.

Grossly, it appears that the deposit is in the surface of the mucous membrane but on microscopic examination it will be found that there is no pigment in the epithelial cells. Instead, the entire deposit of pigment accumulates in the tunica propria of the mucous membrane, where it lies chiefly within the large mononuclear cells. Rarely it extends to the muscularis, and lymphatic involvement has been reported.

Etiology

In attempting to determine the source of these deposits, my reasoning is in accord with that of Bockus, Willard and Bauk, who expressed the belief that the pigment is derived from ingested food which is "phagocytized" by the cells of the intestine. I never have seen melanosis coli in examination of an individual who was not constipated and the frequency with which such a person habitually takes cascara is too striking to be disregarded. Bartle first called attention to the possible relationship between the constant ingestion of cascara and melanosis coli. And in Bockus' review, a complete record is given of the views of various authors on the significance of anthracene and other derivatives of anthraquinone, all of which "contain emodins or trioxymethylanthraquinone" and which, according to Sollman, Tappeiner and Brandl, act largely on the colon. My opinion in regard to the hypothesis that the condition arises as a result of phagocytic action of the mucosal cells agrees with that of Bockus only in so far as it applies to substances which may be picked up by this phagocytic action and does not relate particularly to foodstuffs as such. I believe that this pigment is obtained either directly from elements within laxative agents or from the products which develop as a result of the action of these chemicals on the intestinal content. When it is considered that practically all patients who have melanosis coli are constipated, the likelihood that colonic stasis and its effect on metabolism of foods may play significant rôles in the production of this condition becomes impressive. However, when it is recalled that more than 95 per cent of persons who are constipated, many of whom are not in the habit of taking cascara, show no sign of melanosis of the colon, one leans more toward the belief that this drug, or one of its constituents, or one of its effects, is of significance as a causative factor. With such a large number of constipated patients who do not have melanosis, it seems that the factor of stasis alone is not of great importance but that the limited group with melanosis represents those who ingest some particular chemical which causes deposits in the walls of the colon. Investigations are now being made in an attempt to discover the chemical nature of the material deposited in the colonic wall and its relationship to various laxatives, but unfortunately they will not be completed in time for inclusion here.

Clinical Significance

There is no evidence that the physician should be concerned over the presence of melanotic pigment in the walls of the colon. I never have observed features which suggested pathologic tendencies. The condition has been seen in examination of patients with carcinoma of various parts of the colon, but on each occasion it appeared to have developed as a result of the obstructive effect of the lesion, the consequent stasis above it and the necessity of taking laxatives; it has not seemed that melanosis coli was a cause of the carcinoma. Until the exact nature of the pigment is known, however, justifiable conservatism forbids that one should adopt the arbitrary position that it cannot produce harmful effects, either of a toxic nature or otherwise. But if clinical experience can be relied on, it can at least be stated that those symptoms experienced by patients in examination of whom the condition is found are owing to those disorders such as constipation, colonic stasis, laxative habit, and so forth, which probably are responsible for the presence of the pigment in the colonic mucous membrane.

HINTS ON THE USE OF THE MEDICAL INDEXES*

THOMAS E. KEYS, A.B., M.A.
Reference Librarian, The Mayo Clinic
Rochester, Minnesota

SOME outstanding physicians and surgeons have recommended from time to time that instruction be given to medical students on the use of the library and the indexes that synthesize the medical literature. Dr. John Shaw Billings felt that a course in medical bibliography was important from a practical point of view to teach the younger men the use of the implements of their profession. Dr. Harvey Cushing suggested that short talks on the use of the library for the benefit of the younger men might be made obligatory. And Dr. Bayard Holmes maintained that if medical students were trained in the use of the library they would read with a better sense of discrimination in the active years of a busy practice.

Librarians and editors have similarly felt that both the undergraduate and graduate student need instruction about library tools and library methods. To this end a few medical schools and special libraries have set up brief educational programs. When administrators realize the full value of bibliographic research more time will be spent by more schools on this fundamental instruction.

The medical indexes are the first library tools that the reader should be acquainted with for from them he can find what has been written, by whom, and where the material has been published. In the first place the reader should know how to use the library catalog. In medical libraries, generally the textbooks and monographs the library has are listed in the card catalog. These cards are filed alphabetically, similarly to the arrangement of words in the dictionary. If the reader's primary interest were pathology, for example, and he wished to know what editions the library had of Bell's *Textbook of Pathology,* he would look in the catalog under the B's and under Bell, Elexious Thompson, would be found the required information, one card for each edition of the book in question. If the reader wished to know what textbooks the library had on pathology he would look under the subject heading, pathology, in the catalog and there in alphabetic order would be listed the textbooks contained in the library.

Readers are interested in the articles found in periodicals chiefly for three reasons: 1. The new developments in medicine and surgery are first published in periodicals. 2. The investigator contemplating a new research problem needs to know what has been published in order to avoid duplication, as well as to provide a suitable background for his study. 3. The general practitioner and medical student desire to know at first hand the literature on particular phases of medicine. The chief sources of illumination for such readers are: The Quarterly Cumulative Index Medicus, The Index Medicus, The Quarterly Cumulative Index to Current Medical Literature, and The Index-Catalogue of the Library of the Surgeon General's Office, United States Army (Army Medical Library). Most medical libraries have these indexes and they should be studied carefully.

The best source for the recent literature is the Quarterly Cumulative Index Medicus. This is published by the American Medical Association. Since 1931 the entire cost of publishing this invaluable index has been borne by the association. It is published at a deficit of about $45,000 a year. In making this index available, the American Medical Association is rendering an inestimable contribution to international medicine and its scholarship. The subscription price is only $12.00 a year. More practitioners might well subscribe to this index, for their perusal of it will pay many times over the small initial cost.

The Quarterly Cumulative Index Medicus (here often referred to as the Q. C. I. M.) is issued four times a year. The January to March issue is paper bound and indexes the medical literature for the three-month period. The January to June issue is bound in cloth and is a permanent record. It incorporates the material included in the January to March index. The second half of the year is treated similarly to the first half, with the unbound numbers cover-

*Submitted for publication June 8, 1938.

ing material issued from July to September, and the bound volume covering material from July to December. Because of the large number of periodicals indexed and the mechanical problems of indexing, it is impossible for the bibliographers and publishers to keep the Index up to date. It will be noticed, therefore, that the Q. C. I. M. lags from two to four months. However, compared to other indexing tools, this is of little consequence.

The Q. C. I. M. includes the following items: 1. New books listed (a) according to author and (b) according to subject. 2. List of medical publishers. 3. List of journals indexed. 4. Index to the periodical literature. In the list of journals indexed the accepted abbreviations are given, and these abbreviations should be followed when it is necessary to make reference to the literature. Biographical notes and sketches are indexed under Biographies and also under Obituaries.

The reader consults the Q. C. I. M. as he would the dictionary or the library card catalog, for the index is arranged in one alphabet. This is much more convenient than having the index of authors and subjects at the end of the volume. Articles are listed under subject and also under author. Cross-references and "see also" references help guide the reader to the subject heading under which the articles are listed. It is true that some skill is required to extract all of the required references from the Q. C. I. M. Practical experience should develop an ability to use the index properly. Occasionally it is necessary to use the "trial and error" method before the material can be found. If the material is not listed under the accustomed heading, another heading should be tried. Of one thing the reader can be certain, nine times out of ten, there are good data available. Articles may be listed under general headings with more specific subheadings, for example, spondylolisthesis is listed under Spine—Dislocations. The literature is usually indexed under the simpler form of the name. For example, cancer is used instead of carcinoma. Cancer of an organ of the body is listed under the organ. Example: Breast—Cancer. Diseases that can be classed under the organs are so listed. Example: Eyes—Diseases. The heading, Ophthalmology, is used for the theory of diseases of the eye, apparatus, history and so forth. Some subjects are from necessity grouped under broad subject headings. Example: Acids, Bacteria, Hospitals, Instruments. If the approximate title is known, a good plan is to look under the key word that most adequately describes the paper. In case an article is to be used as a reference, for which correct bibliographic form is necessary, it must be remembered that the complete bibliographic reference is listed only after the author's name. Under the subject heading will be found an incomplete title. Often, for the purpose of ready reference, the title is reversed in form. Titles to foreign articles are translated for the convenience of the reader under the subject. If the title of an article is in a language other than English, French, German, Spanish, Italian, or Portuguese, it appears in translation under the author entry.

The Index Medicus, another important library tool, preceded the Quarterly Cumulative Index Medicus. It was started in 1879 by Dr. Robert Fletcher with the coöperation of Dr. John Shaw Billings, both of the Library of the Surgeon General's Office. The publication was issued monthly and was arranged according to medical subjects. The volumes were bound annually and an index both of authors and subjects was included in each bound volume. This index is hard to use because the numbers were not made cumulative, and consequently, the yearly indexes must refer to articles in twelve separate issues. However, the Index Medicus is very useful in locating an author's work for a particular year between 1879 and 1916; at the end of that period a new index made its appearance.

This new bibliographic tool, The Quarterly Cumulative Index to Current Medical Literature (1916-1926), was published by the American Medical Association. The bound numbers were cumulative and the references by both author and subject were brought together. Accordingly the Index Medicus was combined in 1927 with the Quarterly Cumulative Index to Current Medical Literature to form the Quarterly Cumulative Index Medicus, which has been discussed in detail.

The last bibliographic tool to be discussed is the Index-Catalogue of the Library of the Surgeon General's Office, United States Army (Army Medical Library).

The making and publishing of this index has been called, by some of the most distinguished physicians of the world, America's greatest con-

tribution to medicine. The "Index-Catalogue" is an analysis of the largest, and in many ways the finest, collection of the medical literature in the world.

The "Index-Catalogue" was begun by Dr. John Shaw Billings, father of the Army Medical Liabrary.[4] The first series of the catalogue (sixteen volumes) was completed by 1895. Two more series were completed by 1932. The fourth series of the index (1936-) is now being published at the rate of one volume a year. The advantage of the "Index-Catalogue" over the other indexes is that each series contains the medical literature for a great number of years instead of the literature for a short period. Books, chapters of books, pamphlets and theses are listed under subject and also under author. Under the author entry may also be found references to biographical information if this is available. The disadvantage in using this catalog is that references to articles are not indexed directly under the author's name but are found under the subject only. Because of the tremendous scope of the "Index-Catalogue" it would be hardly possible to list the articles as does the Quarterly Cumulative Index Medicus. The Index Catalogue is more complete than the Quarterly Cumulative Index Medicus, listing more books and journals, and is cumulative for a period of many years. It is ideal for a review of the literature. With the four series in front of him, the reader looks under the appropriate subject in four places (Series I, Series II, Series III, and Series IV), notes the date of the last article and completes the references from that time on by use of the Q. C. I. M.

In compiling a list of references to the periodical literature, the following suggestions are offered. For brevity they are stated imperatively. First of all, limit your subject as specifically as possible. If, for example, you are interested in therapy for pleurisy, consult only the heading: Pleurisy—Therapy. Do not bother with the other headings. However, if you are reviewing such a subject as sulfanilamide in all its different aspects and you desire a total bibliography, consult all the headings under Sulfanilamide and Sulfanilamide Derivatives. Besides this, consult all the "see" and "see also" references. In volume 22 (July to December, 1937) of the Quarterly Cumulative Index Medicus the "see" and "see also" references on this subject alone refer the reader to the following places:

Sulfanilamide and Sulfanilamide Derivatives

Effects: See also Meningococci, infections; Puerperal Infection, prevention.

In blood: See Blood, sulfanilamide and sulfanilamide derivatives.

In urine: See Urine, sulfanilamide and sulfanilamide derivatives.

Therapy: See also Abortion, criminal; Abscess, peritonsillar; Appendicitis, therapy; Arthritis, gonorrheal; Bladder, inflammation; Erysipelas, therapy; Gangrene, gas; Gonococci, infections; Gonorrhea, therapy; Infection, therapy; Jaundice, therapy; Lungs, abscess; Malaria, quartan; Malaria, tertian; Malaria, therapy; Meningitis, influenzal; Meningitis, meningococcic; Meningitis, pneumococcic; Meningitis, streptococcic; Meningitis, therapy; Meningococci, infections; Otorhinolaryngology, therapy in; Penis, gangrene; Pneumococci, infections; Pneumonia, therapy; Poliomyelitis, therapy; Puerperal Infection, therapy; Pyelitis, therapy; Pyelocystitis, therapy; Scarlet Fever, complications and sequels; Septicemia, therapy; Skin, diseases; Staphylococci, aureus; Staphylococci, infections; Streptococci, hemolytic; Streptococci, infections; Streptococci, viridans; Syphilis, therapy; Tonsils, infection, Undulant Fever, therapy; Urinary Tract, infections.

All the references must be consulted if a complete bibliography is desired. From the above examples it can readily be seen that the bibliographic problems for different subjects may vary widely. Experience with the indexes and personal judgment help a good deal in this bibliographic work. Generally the literature is so exhaustive that not everything can be read. The literature for the past five years should be enough to read for an ordinary article. The reader also should decide whether he wants the literature in all languages and should make his selections accordingly. Being acquainted with the outstanding men in a given field also should be of help in making a bibliography selective. Experience teaches that the caliber of certain journals is better than that of others. The journals that that are official publications of societies and those of national reputation should be read first; only then, if at all, journals that accept questionable advertising. Attention to the above points probably will save the reader and the library a great deal of unnecessary work.

I have found that the best way to use indexes is to start with the newest index and work backward. In so doing the reader occasionally picks up a good review article which may save

him considerable time. References to the literature are generally more accessible when made on standard bibliographic cards, and they are convenient for filing for future needs. When bibliographic cards are filled out the entries should be complete. They should include: 1. The name of the author and his initials (if he has two or more Christian names; otherwise, his full name. The full name always is written out if the author is a woman.) 2. The complete title entry. It should be remembered, here, that the complete title is filed only under the name of the author in the Quarterly Cumulative Index Medicus. 3. The name of the journal. This may be in the abbreviated form suggested by the Q. C. I. M. 4. The volume number, the inclusive pagination, the month and the year. This information is necessary if the bibliography is to be helpful to anyone else.

It is well to remember that the scientific quality of an original work can be judged somewhat by the excellence of its bibliography; that is, if the references are incomplete and inaccurately cited, the results of the author's original work may be thought to be unreliable. Of course, a great scientist may be a careless bibliographer, but the bad impression made by carelessness in any field is one good reason for taking pains in the first place and for verifying the references when a bibliography is compiled.

THE USE AND MISUSE OF MEDICAL TERMS: SOME SUGGESTIONS FOR IMPROVEMENT

H. E. Robertson, M.D., Section on Pathologic Anatomy: There is an old saying to the effect that those who live in glass houses should hurl stones with considerable discretion. . . .

With this in mind . . . I am proposing that we modify our employment of certain terms.

First I am advocating a change in the words "lymph gland" to "lymph node." "Gland" was perhaps permissible when no one knew the nature of these collections of lymphocytes. Now, whatever they really are, we feel certain they are not glands. Your first answer may well be, that the term "lymphadenitis" means "inflammation of a gland" but we use it exclusively to mean "inflammation of a lymph node." Right at the start I am in a bad position for I do not like "lymph noditis." But I still persist in suggesting the change to lymph "nodes."

My next proposal is concerned with the term "epithelioma," by which we usually mean a "squamous cell carcinoma." The word is illogically used, as all kinds of carcinomas are epitheliomas and hence the word loses it specific signification. Whatever term is employed to characterize carcinomas of squamous epithelial surfaces (and I suggest the name I have just used), "epithelioma" has no place in the nomenclature of tumors and should be dropped.

The adjective "colloid" which qualifies some of the carcinomas in our writings is inappropriate and inaccurate. It refers to the gelatinous appearance which some tumors possess, almost wholly owing to the presence of large quantities of mucus secreted by the epithelial cells of some cancers. A much better term would be "mucous" (not mucoid) carcinoma.

The word "mucus" brings to mind a much more debatable word, "myxoma," which we employ to designate certain connective tissue tumors which contain appreciable quantities of interstitial mucin. This form of mucin is found in all sorts of tissues other than tumors. It is a normal constituent of the walls of the arteries, it is the basis for the various myxedemas, elephantiasis and other chronic edemas and is often found in leiomyomas, so-called fibroma sand other fibrous tissue masses. There is probably no such entity as a "myxoma" in the sense of a specialized tumor. Instead we should describe such tissues, whether neoplasms or not, as "myxedematous."

In considering the "adenomas," I at once am in deeper water. Without entering too far into a discussion of this complicated group, I would suggest that we restrict this term as much as possible to neoplastic conditions. This would exclude its use for "nodular repair" of the liver in cirrhoses, for "nodular goiter" and "nodular prostate" in focal hyperplasias of these organs and limit the term largely to new growths of the pituitary, and adrenal glands and pancreatic "islands."

A favorite of even our more cultured confreres is the word "fibroid" meaning a leiomyoma of the uterus. When the true nature of these smooth muscle collections was not known, perhaps fibroid was permissible, but now it is, at its best, medical slang. Even the combination "fibromyoma" is probably not correct. Leiomyomas may partially be replaced by fibrous connective tissue, which in turn may be myxedematous, calcareous, osseous, or necrotic. Hence the correct designations might be fibrous, calcareous, and so forth, leiomyoma of the uterus, stomach, esophagus or other organs.

Medical slang is perhaps, as in all languages, a forerunner of future correct usage, but to these old ears much of it is, and probably always will be, an anathema. "The surgical abdomen," "he had a gallbladder" or "I did his gallbladder," "he had no temperature," "round cell infiltration" for collections of lymphocytes, "the liver showed malignancy" and so on with a list that has no ending, and against which medical editors thunder loud and often.

May I pause over one particular pet aversion—namely, the wrong use of the word "pathology." For example, often I hear the expression, "There was no pathology in the abdomen," or "the specimen showed (sic!) no pathology" or "the surgeon found pathology in the liver." Here the word is employed to mean "lesion," "disease condition" or "pathologic condition." When it is used in this perverted sense, it indicates to my mind, a distinct pathologic complex in the user's mental makeup, education, or mode of thought.

—Proceedings of the Staff Meetings of the Mayo Clinic, March 3, 1938.

MEDICINE IN WASHINGTON AND CHISAGO COUNTIES

(Continued from July issue.)

Beginning with the seventies, the history of the counties is easier to trace. Records of the Board of Health and of local medical societies, available periodicals of various sorts, some early directories, and the Transactions of the State Medical Society all supply bits of information.

The newcomers of the seventies were numerous. In 1870 Taylors Falls gained Dr. A. J. Murdock, and Stillwater Dr. B. G. Merry. Although Dr. Merry was a dentist, he did much research in mouth infections and wrote an excellent article on that subject which was published in the *Northwestern Medical and Surgical Journal.* He also served on the first Board of Dental Examiners for four years, the last year as president. In 1871 Drs. W. H. Pratt, Th. Roehrig, and David Sime, settled in Stillwater. Sime had graduated with honors from Glasgow University, and had attended both Glasgow and Edinburgh hospitals, being for some time resident physician and surgeon at the former. He stayed in Stillwater only a few months, however, before leaving for his former home. In 1872 Dr. Perry H. Millard arrived at Stillwater. Millard had studied chemistry at the University of Michigan, and after graduating had gone to Rush Medical College. He then settled in Chicago to practise, but left after the Chicago fire, which destroyed his office and everything in it. He came to Stillwater then, and stayed for many years, finally moving to Saint Paul. The same year three others arrived: Drs. George A. Lambert, R. F. Goodwin, and E. Cooley; the two latter were homeopaths. In 1873 Dr. Wm. A. Bentley and Dr. Q. C. Thompson settled at Rush City, Chisago County; as far as records show, they were the first physicians there. In the same year Dr. F. Hefti, a "practical physician," announced his presence in Stillwater. In 1874 Dr. A. H. Steen settled in Cottage Grove; Drs. Edson R. Wait and R. A. Livingston in Stillwater. All three of these were Rush graduates. Dr. F. L. Puffer, a graduate of the University of Michigan, came to study under Dr. Murdock of Taylors Falls. The year 1875 was rather uneventful. Two physicians, Drs. G. H. Hawes and C. Adams Sheeley, came to the valley but stayed only a few months each. Sheeley later moved to Pine City, then to Grantsburg, Wisconsin. At Harris, there was a Dr. Wilkes, but nothing is known of him save his name, and that he left in February at the request of his wife, who financed his departure on the condition that he never return. In 1876 Dr. E. A. Umland, a German, settled at Franconia, but a year later moved to Rush City where he became one of the most prominent physicians. Also a Dr. Zuercher settled at Stillwater and Wm. Olding, a Swedish cancer specialist who guaranteed a cure in every case, moved into Chisago County. In 1877 Dr. T. R. Austin came to North Branch; a Dr. Ogden to Center City, Dr. W. H. Caine to Stillwater, and Mrs. Sorenson, who specialized in female diseases, to Taylors Falls. The latter two were both homeopaths. In 1878 Dr. J. Reginald DeCousens moved to Rush City. He had been practising for some time before this in Isanti County, and was well known along the valley. He stayed at Rush City only a short time. A Dr. Lamb also came to Rush City in 1878, but stayed only a year. A Dr. J. N. Allen practised a short while in Stillwater. In 1879

Drs. Woodling and Chapman came to North Branch, Dr. Oscar Hallberg to Marine, a Dr. Hunter to Center City and Dr. C. F. McComb to Rush City. Dr. McComb later moved to Duluth and at one time was mayor of that city. These, then, were the newcomers of the seventies; they included in their number some of the most prominent physicians who ever practised in the valley.

The health of the people of the two counties during the seventies was in constant danger from a great variety of epidemics which were always present and showed remarkable persistence in spite of the many physicians. In addition to the smallpox alarm in March, 1870, there was a severe typhoid epidemic in all the towns in the valley. One elder at Stillwater was called on to attend six funerals in one week. Dr. Rhodes himself had a slight attack of it. In Volume II of the *Northwestern Medical and Surgical Journal,* in the report of the Committee on Climatology and Epidemics for 1871, Dr. Reiner reported in Washington County during the year sixty-five cases of fevers, twenty-three enteric and the balance entero-malarial; twenty-two cases of scarlatina, nearly all mild and no deaths; twenty-six cases of diphtheria with four deaths; fourteen cases of erysipelas; six cases of cerebro-spinal meningitis, with three deaths; thirteen cases of acute rheumatism. No account was kept of rubeola or dysentery, but all cases were mild and there were no deaths. The year 1872 was somewhat more healthful. Although there is no available report for the year, the newspapers mentioned only smallpox, which was reported prevalent at Taylors Falls in October. However, in April, 1872, an ordinance was passed by the city council of Stillwater as follows:

"Every practising physician or other person attending or having under his care or become directly or personally cognizant of the existence of smallpox, varioloid, cholera or any other infectious, malignant or contagious disease within the city of Stillwater must within 24 hours report to the city recorder or the chairman of the Board of Health the disease, the name of the afflicted person, and the house or place of infection."

The ordinance also provided for a fine of from $75 to $100 for anyone willfully neglecting to do so. It went into effect April 22, 1872. This ordinance and a severe quarantine system, helped but little in keeping down epidemics. The next year there were deaths from diphtheria, measles, spinal meningitis and typhoid. At Chisago Lake and Franconia there were four deaths and several other severe cases of scarlet fever in one month. Apparently, however, this was a comparatively healthful year, for at the State Medical Society's meeting in February, 1874, Dr. Reiner said that they had "a season of immunity from epidemic diseases during the year." The fall of 1874 was marked by measles and whooping cough epidemics at Taylors Falls, and the diseases persisted through the following spring. They were followed by a much more serious visitation of scarlet fever, which was precedent throughout Chisago County and lasted through 1875 and the early part of 1876. It died out for a year, and then in September of 1877 returned and for five or six months was extremely severe. Several schools were closed as a precaution. At one time there were as many as eighteen cases in the small town of North Branch, though most of them were mild. This epidemic was punctuated by smaller, contemporary epidemics of whooping cough and typhoid. By the time these were out of mind an epidemic of diphtheria visited Stillwater during the summer of 1878, and in January and February of 1879 touched North Branch and Rush City at the same time as typhoid, membraneous croup and pneumonia prevailed. When these were over, and the threat of the return of scarlet fever was past, Rush City came down

with a severe epidemic of measles which kept Drs. Umland and McComb busy day and night. At the end of the decade typhoid came again to Rush City.

In spite of all these diseases, the physicians seemed to have had plenty of time to take part in other activities besides practicing their professions. Dr. Carli found time to be city physician and chairman of the Board of Health, and in 1876 president of the St. Croix Old Settlers Association. In February, 1878, he bought and reopened the City Drug Store, which he had established twenty-five years before. Dr. Gaskill was one of the first supervisors of Marine, and for many years one of the inspectors of the state prison. Dr. Griswold was treasurer of the library association and chairman of the Republican county convention. Dr. A. J. Murdock was a charter member of the Temperance Society in October, 1877, and examining surgeon for the United States pension department, a member of the school board in 1877, and 1871 county physician. Dr. Reiner was a member of the board of education and prison physician at the time of his death in January, 1874. He was succeeded in this office by Dr. Lambert, who was in turn succeeded by Dr. W. H. Pratt. Dr. Rhodes was a member of the Board of Education and city physician in 1873 and 1874. Dr. Runge started a drug store in 1871. Several other physicians also conducted drug stores, among whom were R. F. Goodwin in 1875, Chapman at North Branch in 1879, and C. F. Forssman at Taylors Falls in 1870. Dr. Whiting was a delegate to the Republican district convention, was president of the St. Croix Bridge Company in 1874, to which position he was re-elected in 1875, and was several times elected president of the library association. Dr. Steen found time to collect a large and well selected medical library. Dr. Lamb was for three years government physician at the Pawnee and Winnebago agencies. The position of county physician was held by Dr. Pratt in 1874, and beginning March, 1875, by Dr. Livingstone, who held it until his death. In 1877 the position was held by Dr. Millard, and in January, 1879, the position was again given to Dr. Millard at a salary of $300 per annum. Millard also frequently served as a delegate to the State Medical Association, and in June, 1876, was delegate to the American Medical Association. Many of the doctors were enthusiastic hunters and fishermen, and Dr. C. F. McComb owned a particularly fine horse which won several races. Dr. DeCousens was a United States pension examiner and Dr. Umland sold insurance.

At Rush City, Dr. Wm. A. Bentley took an active part in civic affairs; he was one of the leading men in the temperance movement, was a United States pension examiner, was chairman of the Republican district convention, and in November, 1876, was elected representative from the district. While representative he introduced a temperance bill, which, though defeated, had the honor of receiving the largest vote any such bill had ever received up to that time. He was a member of the Literary Circle. In 1875 he gave two lectures to the Teachers Institute on "Hygiene in Our School" and "Physical Culture as the Legitimate Base of All Mental and Moral Development." He spoke at the State Medical Association meeting in February, 1876. Like most politicians, Dr. Bentley had enemies, among whom unfortunately was the editor of the *Rush City Post.* The editor was in the most advantageous position; he could say anything he pleased and spread it among the many readers of his paper, and he did so. Finally Bentley called at the editor's office in a fighting mood to settle the affair. He found the editor, Mr. Robie, prepared; the floor was carefully greased and a keg of diluted ink had been placed where it would do the most good. At the first blow the doctor's heels flew up, and the editor "lit on him like a grasshopper onto a cornstalk," at the same time upsetting the keg of ink. Robie got

his hands in Dr. Bentley's hair and proceeded to mop up the floor very effectively before friends separated the two. Suitable apologies and explanations were made, but Bentley left town not long afterward and never returned.

Mrs. Sorenson, in November, 1877, opened the first hospital in Chisago County. Just what sort of hospital it was is unknown, but she offered homeopathic and electrical treatment and free treatment in the eye and ear department on Thursdays. This hospital was kept up until Mrs. Sorenson was appointed county physician of Polk County, Wisconsin, and moved to St. Croix Falls. In April, 1879, she established a hospital there. During the seventies another medical society was formed in Washington County. Although it was apparently fully organized and existed for several years, its history is only known by a series of six newspaper items in the *Stillwater Gazette* and the *Stillwater Messenger.* The first item, published June 6, 1871, was as follows:

"We are requested to announce that a meeting of all the regular physicians of Washington county will be held at the office of Doctor Carli on Thursday evening of this week at eight o'clock. The object of the meeting is to take steps for the organization of a 'County Medical Society.' Every physician in the county is earnestly requested to be present."

The second item was published June 20, 1871:

"St. Croix Medical Society"

"The physicians of the St. Croix Valley are requested to meet at the office of Dr. J. K. Reiner on Saturday evening next June 24 at eight o'clock. A full attendance is desired, as it is the wish and intention to perfect the organization at that time."

The third item was a brief letter from Dr. Roehrig, published in the *Gazette* for August 15, 1871, announcing his withdrawal from the St. Croix Medical Society. Evidently there had been a misunderstanding of some sort, for Roehrig left town shortly after. Then on September 16, 1873, there was a report of a meeting at the office of Dr. Millard. A committee to prepare a fee bill was chosen, consisting of Drs. Millard and Pratt, and a resolution was adopted which provided that each member furnish a black list of patients whose bills were not paid, and that no other physician should render any medical service until such debts be settled. At this meeting it was decided to admit Dr. Lambert to the society upon presentation of his diploma. The next report was merely a statement that the St. Croix Medical Society of Minnesota meeting was held at Dr. Livingstone's office with full attendance. This was in March, 1875. The last item was the news of a special meeting on September 10, 1875, to adopt suitable resolutions on the death of Dr. Livingstone. These are the only records of this society. There is no way of telling who the officers or members were, but in the obituary of Dr. Reiner in the *Gazette* for January 20, 1874, it was mentioned that he was secretary of the organization.

During the seventies a board of health was organized in Stillwater. It was first appointed on May 5, 1874, and consisted of Dr. Carli, William Casey and Dan Fry. Dr. Carli held the position of chairman for several years. Taylors Falls and Rush City apparently had no boards of health at this time.

Several of the pioneer physicians died during this decade. Dr. B. F. Babcock passed away at Afton on September 19, 1870, and Dr. Henry I. Jordan of Stillwater on October 16 of the same year. It is not known what caused either death. On August 2, 1872, Dr. J. N. Ahl died of a paralysis after six days of illness. He was one of the earliest practitioners in the valley. Less than a year later another pioneer, Dr. H. F. Noyes, died at Milwaukee, where he had retired

two years earlier, because of his age, to live with his son. Noyes was a skillful surgeon in his day and did most of the surgical work at Stillwater when he was there. Exactly a year later, on January 20, 1874, he was followed by Dr. J. K. Reiner. Reiner had been assisting Millard, Pratt and Carli with an amputation and contracted blood poisoning. In 1875 came the tragic and untimely death of a young physician, Dr. Livingstone. On September 8, after suffering for some time from severe indisposition, he took a hypodermic of morphine. Feeling no relief, he also took five grains by mouth, remarking that he should have "a good night's sleep." About 11 o'clock his wife became alarmed and sent for her half-brother, Dr. Millard. Several other physicians were also called in, but could do nothing, and Livingstone died before morning. Another young physician who died was Edson R. Wait, who died of a severe cold combined with tuberculosis in February, 1877.

Several physicians left the valley during this decade, besides those previously mentioned. Kinkle left in August, 1876, moving to St. Cloud. Lambert left Stillwater—and a number of indignant creditors—behind him in December, 1875, and died the following August "after a protracted debauch." Puffer, after completing his study of medicine with Dr. Murdock of Taylors Falls, and having practiced there for a while, left in February, 1878, to settle at Beaver Falls. The other physicians presumably stayed in Washington or Chisago Counties.

During the early eighties an even greater number of physicians arrived in the valley. In 1880 Dr. Oscar Hallberg, who was a graduate of the Carolinan Institute of Stockholm and who spoke Swedish, German and English fluently, settled at Taylors Falls. Dr. Weiseman, or Wynsma—it may have been two different men, or merely a variation in spelling—came to Center City and stayed a year. A Dr. Jackson, who was also, conveniently, a reverend, came to North Branch. Dr. Chapman also spent the year there. Dr. M. P. Goodwin, physician and dentist, came to Taylors Falls from Hudson, but moved to Stillwater in October, and later to Clear Lake. Several others came to Stillwater: Drs. O. A. Watier, Alfred Fliesburg, Alexander Donald (a homeopath) and A. Chisholm. They were joined the next year by Dr. Mark Edgerton, who came and formed a partnership with Drs. Caine and Hood (both homeopaths) and Dr. Jurden, a "noted chronic physician" who cured cancer, heart disease, syphilis or anything else presented. A Dr. M. Whittier ran a stationery and musical store that year, and Mrs. M. C. Hancock, a nurse, stayed for a while. The most important arrival of that year, however, was that of Dr. T. C. Clark, who settled at Stillwater, where he remained for many years, later becoming surgeon in the State Soldiers Home in Minneapolis. Dr. H. C. Murdock, a brother of A. J. Murdock, came to Taylors Falls at that time to take care of his brother's practice when the latter was absent. Later he took over the practice entirely when his brother moved away. In 1882 Dr. Wm. Jenner stayed for a while at Stillwater. Dr. H. S. Hersey also practiced there until March of that year. Dr. Merrill came from Hudson to form a partnership with Dr. Millard, and in 1883 James Sinclair began to study medicine with Dr. Caine. About that time a Dr. Beardsley settled at Rush City, and a Dr. Robb at North Branch, who stayed about a year. In 1884 Dr. J. G. Hodgkinson, from Saint Paul, located at Taylors Falls, Dr. Geo. B. McGuin at North Branch, Drs. W. D. Bolles and Leonard Pitkin, and again the much-moving Dr. Kinkle, at Stillwater. Dr. T. J. Hutton was at Taylors Falls at this time. The next year Stillwater gained Dr. E. R. Jellison, Dr. Charest (who came from Montreal and stayed only a short time) and Dr. Sinclair, who had once studied medicine with Dr. Caine, and later at the Hahnemann Medical College. A Dr. Carpenter practiced at Marine.

If prevalence of disease attracts physicians, there was small wonder that so many new ones came at this time; besides mild annual epidemics of measles, frequent threats of an outbreak of mumps, whooping cough, scarlet fever, small pox, chicken pox and cerebrospinal meningitis, typhoid fever was constantly present and occasionally assumed alarming proportions. In September, 1882, there were some fifty cases of typhoid in Stillwater alone. The most serious disease was diphtheria. This disease, which killed fifty-nine persons out of a population of 7,997 in Chisago County in 1879, appeared as a severe epidemic and lasted until the winter of 1884, after which it very gradually died down until only an occasional case was reported. It was by far the most serious and longest epidemic the valley had ever had. Not only individuals, but often nearly all the children in a family died. In April, 1881, four children in one Taylors Falls family died. A year later the village council of Rush City was moved to order several barrels of chloride of lime and "proposed to disinfect the whole town." In July, 1883, one Stillwater physician alone reported ten cases under his care, and in August at the same place an undertaker reported that he had sold fifty-five coffins within two months. *The Stillwater Messenger* admitted that the disease was increasing. Dr. Carli's house was a regular hospital, two visiting relatives and a servant having contracted the disease. In Taylors Falls in November, 1883, not only were schools closed, but churches and Sunday schools did not meet. In Osceola, across and down the river, even the saloons were closed! In the family of John Ekegren of Stillwater, six children were prostrated at one time; a month later (January, 1884) four children of Jonas Grandstrand, who lived six or seven miles north of Marine, were buried at one time—three of them having died within twenty-four hours, and the fourth a few hours later. In Stillwater, in June, 1885, a girl, fourteen, and her brother six, died; several other members of the family had died during the two previous years, leaving only two children of a large family. Other cases were too numerous to mention. Quarantines were apparently enforced quite strictly at this time, but often the disease spread far before it was recognized. Often a well-meant visit to a friend with "a sore throat" resulted in a spread of diphtheria. In one case several neighbors dropped in to see if they could help care for a sick baby; the next day the baby died of diphtheria, and shortly afterwards the neighbors, and in turn their families, came down with the disease. In February, 1880, there were five cases of diphtheria in one family near Taylors Falls. The entire family lived in a one-room house, which was tightly sealed in the winter, and which had no sanitary arrangements at all. Naturally, if one member of the family contracted a contagious disease, the rest of the family could hardly hope to escape. Another case, which shows how the epidemics were carried, occurred at Fish Lake, Chisago County. A traveling Adventist minister, Mr. Carlson, came from Isanti County, where he had been in an infected house, praying over the body of a boy who had died of the smallpox. Taking no precautions, and without warning his host, he came to Fish Lake and stayed overnight at the home of a Mr. Almquist. That was on the fourth of December; on the fifteenth two daughters of Mr. Almquist were taken ill. The minister, who professed to have some knowledge of medicine, came again and assured them that it was only measles. However, he took the precaution of vaccinating the rest of the family. The vaccinations did not work, and Mr. and Mrs. Almquist and two other children caught the infection, which was, of course, smallpox. One of the girls died, though the rest of the family recovered. Another disease which was especially prevalent in 1885 and 1886 was scarlatina.

Unsanitary conditions, in at least some of the towns, greatly encouraged epidemics. During the earlier winters, before sewers were constructed, refuse of all sorts was merely thrown out on the snow, where it soon sank from sight. Most of the river towns were built on hillsides, so that when spring came and the snow melted, quantities of refuse was washed down the streets and scattered liberally throughout the town, often draining into cellars and remained there in stagnant pools. By the eighties this was partly remedied, but the *Stillwater Messenger* of July 14, 1883, reported that conditions were still "frightful." According to that paper, "Scarcely anything has been done in the way of cleaning up or disinfecting rear yards, alleys, open sewers, water closets, while in many places ponds of stagnant water can be found on which a thick green scum has formed. Unless immediate steps are taken . . . we will soon witness such a harvest of deaths as was never before witnessed in Minnesota."

While mentioning the subject of disease it might be of interest to remark on the sudden increase of cancer noted after the death of Ex-President U. S. Grant in 1885. The quacks, at least, made quite a fad of this disease and used it as the excuse for many operations.

The Stillwater Board of Health was active at this time, and in March, 1883, Taylors Falls established a board of health, which consisted of Dr. H. G. Murdock, E. C. Reynolds, and L. F. Snow. The first official act of this board was announced the next day; it was an order that all persons who had not been, or had not recently been vaccinated should do so within one week. Rush City also formed a board of health. There is no record of when this was done, but it is known to have existed in March, 1884, at which time Dr. Umland served on it.

In March, 1880, a group of women at Stillwater organized the first hospital at that place. The women managed it themselves, collecting beds, clothing, medicine and money by means of benefit parties and donations. In the *Messenger* for October, 1882, appeared the following request: "The animal which furnished milk for the city hospital strayed away some ten days ago, and our philanthropic citizens are requested to furnish a substitute." In 1890 the city contributed $300 per year, and the county agreed to pay at the rate of a dollar a day for each county charge.

Two other hospitals—one a homeopathic institution—were established about 1881. W. H. Caine was house physician and surgeon, Alexander Donald was oculist and aurist, Drs. Edgerton and Dorion of Saint Paul and Dr. Steek of Minneapolis were the consulting surgeons, and Drs. Hutchinson and Humphrey of Saint Paul and Minneapolis, respectively, were the consulting physicians. This hospital was also supported partly, at least, by benefit parties, records of which appeared in the newspapers of that time. This hospital apparently did not last very long, evidently being closed in the spring of 1883, for at that time Dr. Caine was patronizing the city hospital, which he continued to do until he was excluded from the grounds "for conduct unbecoming a physician and a gentleman." He was permitted to return after he threatened to sue the managers. The managers later quarreled with Drs. Merrill, Marshall, and Millard. The third hospital was established in March, 1885, and was especially devoted to the care of lumbermen and private patients.

(To be continued in September issue.)

Roentgen Therapy

RADIATION therapy during the present century has developed into one of the dominant therapeutic means available to the medical profession. It is best known as a weapon in combating cancer but its field of usefulness has gradually extended to almost all medical specialties. Like all new tools it has often been misused and has occasionally been enthusiastically hailed as the remedy for a disease which later was found to be uninfluenced by radiation. This should, however, not be used as an argument against the sane use of radiation therapy. Unfortunately conclusions concerning the effectiveness of a therapeutic agent are often drawn too hastily. An extensive use should not be attempted until the beneficial effect has been definitely established by careful tests. It is also important to have a clear concept of what is supposed to be accomplished by the treatment. Radiation therapy is often used to relieve pain or to cause a temporary improvement of patients suffering from advanced stages of cancer. Consider for instance the numerous patients suffering from painful bone metastasis who by means of roentgen therapy have been relieved of the pain and from a completely helpless condition have been able to return to active life for one or more years. Though these patients eventually succumbed to the cancer, they received all the benefit from the treatments which could reasonably be expected. It is evident that the patients should be carefully studied and selected before any therapy is inaugurated and the treatments should be planned individually. If it seems possible to obtain a cure the procedure is usually much more radical than when palliation is the only hope. Many "five-year cures" have been obtained with radiation but the percentage cure is as yet small when the whole group of cancer patients is considered. The present method of building up the dose to a very high value in a period of about one month has led to better results. The relatively higher cure rate can, however, not be obtained unless the total roentgen dose is so great that it produces rather severe tissue damage and vesiculation of the skin is often a necessary stage of the reaction that the patient has to contend with.

It was mentioned that many diseases besides cancer can be favorably influenced by means of roentgen therapy. The treatments of many types of infections has become an important field in radiation therapy but it requires careful selection of cases. The dose is as a rule small and severe reaction should be avoided. Just as radical treatments are essential from the start for malignant conditions so it is important to use special caution and to avoid unnecessary damage for benign conditions.

Due to the fact that the macroscopic changes following roentgen therapy develop slowly and may manifest themselves months or even years afterwards it should be evident that considerable

study and experience must be a requirement for the specialist in this type of therapy. The dose used in each case must be carefully chosen and accurately measured and the distribution of the radiation through the cross section of the body considered. Adequate protection for all who work with or in the immediate vicinity of a roentgen machine is another important consideration.

Radiation therapy compares in several respects to surgery and requires just as intense continued practice and study. It has little in common with radiography except that it utilizes similar machines and that it has become a common practice for one man to specialize in both of these divergent fields. A physician may, however, be an outstanding specialist in roentgen diagnosis without being a roentgen therapist and vice versa.

The sane use and development of roentgen therapy is determined largely by the medical profession as a whole. Specialists in this field have to rely upon the support and coöperation of other physicians. A great step in this direction was taken when the American Medical Association started to coöperate with the American Board of Radiology. The important function of this Board is "to issue a certificate to each candidate who meets the requirements of the Board, to the effect that the holder of the certificate has adequate training in Radiology and has successfully fulfilled the requirements of the Board." Different forms of certificates are issued. Either it is to the effect that the applicant has been qualified to practice Radiology in all its branches or else that he has been qualified to practice Radiology in one or more of the special fields. Among these special fields are included Therapeutic Radiology and Therapeutic Roentgenology.

Anesthesiology: A New Specialty

"ANESTHESIOLOGY," said Stedman, in 1933, is "the science that treats of the various means of inducing local or general anesthesia and of the accidents and complications of this condition." This definition affords an interesting and well-founded contrast to the title of Paluel J. Flagg's book "The Art of Anesthesia," published in 1910.

Ever since its introduction, ninety years ago, efforts have been made to improve the quality of anesthesia, both by trying to lessen its dangers and increase its comforts to the patient. For a long time these efforts were concentrated on making the administration of the three original anesthetic agents safer and less disagreeable. Of the three, ether made much the best showing, for the inherent dangers of chloroform could never be eliminated and nitrous oxide, in those days, was thought of only for the short cases and chiefly in dentistry. Ether became the first choice and when the open drop method came in anesthesia became an art and so remained until the turn of the century and even later. Then began important development in the whole field of local and general anesthesia. The refinement of preanesthetic medication, the introduction of the newer gases and ingenious methods of their administration with intensive study of their peculiarities and the means to prevent any untoward effects, the use of helium as a carrier in certain contingencies and the adoption of procedures to diminish the post-anesthetic sequels are a few of the improvements which have been worked out in this later period. In local and spinal anesthesia similar advances have been made, ensuring safer and surer results, with correspondingly wider applicability to all types of surgery.

Naturally all this has contributed largely to the strides which surgery itself has been able to make in this period. New fields have been successfully invaded and difficult, time-consuming procedures made feasible by the application of these newly found principles in anesthesia. They have done much for all kinds of surgery, but the most apparent is probably in that of the chest, so long hallowed ground for anything but emergency operations but now invaded with relative safety for extensive, premeditated and prolonged efforts.

The anesthetist who is to be in a position to meet all the demands of modern anesthesiology must have had considerable training, in addition to fulfilling all the requirements of the complete course in medicine in all its branches. A great deal of ground is covered by the accumulated knowledge of this new science and one must be prepared to undertake a long period of study and demonstration in proper environment. The number of persons who may be considered to be fully qualified in this field is at present very

small and scattered, for naturally enough they are to be found only where there is sufficient demand for service of this highly specialized type. But they are training others and in due time there will be enough to furnish every community where there is the necessary volume of surgical activity with an anesthetist of the requisite ability to comply with the exacting requirements which have been described.

Very wisely, we think, the new American Board of Surgery has established an affiliate which will be known as the American Board of Anesthesiology, an arrangement which has been approved by the Advisory Board for Medical Specialties. Coöperating societies include the Section on Surgery of the American Medical Association, the American Society of Anesthetists, Inc., and the American Society of Regional Anesthetists, Inc. This board, composed of nine members well known for their standing in the field of anesthesia, will hold examinations and issue certificates in much the same way as is done by the other special boards.

G. C.

Dr. E. A. Meyerding

AT the time of the annual meeting of the Minnesota State Medical Association held in St. Cloud in 1924, the idea of having a full time secretary for the Association came to a head. Until that time the secretary was paid a nominal sum for attending to duties which were for the most part in connection with the annual meetings. It was at this time that Dr. E. A. Meyerding, who had proven himself an efficient executive secretary of the Minnesota Public Health Association, was induced to also become secretary of our State Association. With his assumption of the office, the State Association changed its passive attitude to one of widespread activity. Dr. Meyerding furnished much of the drive to the Association's activities since 1924.

Advantageous as it has been in many respects to both organizations to have them closely bound with the link of a common secretary, the job was a man killer, and Secretary Meyerding had expressed the desire to retire before his leave of absence for a year was granted at the 1937 meeting. At the annual meeting this year, his resignation was accepted, not, however, without an expression of the Association's appreciation of his services.

The following resolution was passed by the Council and House of Delegates on June 28 in Duluth:

"Resolved, that the Minnesota State Medical Association provide an appropriate token to be awarded on occasion to a member of the Association who has rendered especially valuable and distinguished service to the Minnesota State Medical Association. The Council of the State Medical Association are to select candidates for this award."

On June 29, the Council passed the following resolution:

"Be it resolved, that the first recipient of the distinguished service medal awarded by the State Medical Association be given to Dr. E. A. Meyerding in recognition of years of faithful and excellent service rendered to the Minnesota State Medical Association."

This is a most fitting way for the Association to express its appreciation of Dr. Meyerding's long and efficient service as secretary.

Human Rabies Doubted by Dr. Brady

THE presence of rabies in the canine population of Hennepin County during the past few months and the finding of an infected dog recently in Ramsey County has brought the disease again into the limelight. The presence of an epidemic makes it incumbent on the health authorities to institute control measures and requires the wholehearted coöperation of the public. As a rule, this is not obtained. Dog lovers oppose the muzzling ordinance and the physiognomy of certain breeds is not conducive to the use of muzzles. Certainly the use of muzzles, leashes and fences will not control an epidemic if stray dogs are not picked up, for it is the stray dog that is the worst offender.

With the announcement in the *Saint Paul Pioneer Press* that regulations would be extended to Ramsey County and of the health officer's request for coöperation in carrying out the ordinance on the part of the public, the same article quotes from the columns of its medical advisor, Dr. Brady, which appeared July 17 as follows:

"I do not doubt that rabies occurs in animals. I merely doubt that it occurs in man. . . . If I were bitten, whether the animal was suspected of having rabies or not, I should want first aid treatment by a competent physician (*good judgment*), and in view of the

chance for tetanus infection, an immediate injection of tetanus antitoxin five to seven days later (*whatever that means*). . . . That would be all. I wouldn't care how mad the animal was before or after he bit me." (Italics ours).

All the medical literature on rabies in human beings from the time of Pasteur to the present has not convinced Dr. Brady. Pasteur's outstanding contribution in providing a method of immunizing human beings bitten by mad dogs and preventing a sure and horrible death is of questionable value in Dr. Brady's mind. Let him be a "doubting Thomas" as far as he personally is concerned. Few physicians have seen cases of human rabies and none wants to, for there is no specific treatment and death is sure. But, Dr. Brady assumes a grave responsibility when he gives advice publicly which no conscientious practitioner would dare to follow if confronted with a patient bitten by a rabic animal. We doubt whether a jury would acquit a physician who failed to use the Pasteur treatment even though he might refer to Dr. Brady as an authority.

The attitude of a newspaper in spreading doubt as to the existence of danger to human beings in a rabies epidemic in dogs is not cooperating with the health department. Wholehearted coöperation of dog owners, as well as health department ordinances, is necessary to stamp out this real menace.

Government Activity Against Poisonous Contaminants

Recently the Food and Drug Administration has been issuing monthly news releases concerning its actions. Under the subheading "Other Food Seizures" (March 22) reference is made to "54 gallons and 310 small bottles of flavors and solvents containing poisonous glycols; and 515 bushels of apples carrying excessive spray residue." Similar seizures are reported also for April. The recent Elixir of Sulfanilamide-Massengill incident focused attention on diethylene glycol. Toxic glycols have been used in the food and drug industry, such as "Carbitol," which is the mono-ethyl ether of diethylene glycol; this apparently is more acutely toxic than diethylene glycol. The dosages containing "Carbitol" were so small that deaths apparently occurred rarely if at all. From time to time The Journal has warned against the potential harm of sprays for fruits containing lead or arsenic. The government deserves considerable encouragement in having reduced this hazard by requiring careful removal of spray residue from fruits sold in interstate commerce. The hazard of lead cannot be attributed to any one industry or source. Whether the source of lead is contamination of drinking water, the increasing amount of lead of exhausts from automobiles, fruit sprays from lead solder or other sources, it is a hazard. (J.A.M.A., June 4, 1938, p. 1929.)

Communication

SIMPLE TREATMENT FOR MAGGOTS

To the Editor:

July 20, 1938.

Ever since reading about the case of "Wohlfartia Vigil Cutaneous Myiasis in Minnesota" in your June, 1938, number by Drs. Vandersluis and Whittemore of Bemidji, I have wanted to write you about my experience with maggots. Little did I realize that my experience might in any way be unique or of interest to any one. My principal reason for writing is to inform those who may have cases, of a very simple and effective treatment.

About 25 years ago I was called twelve miles out in the country to see a baby about six months old. When I arrived I found a much agitated mother and a squirming baby. The mother informed me that she had noticed maggots crawling out of a tiny opening in the skin of the baby's neck. I was a bit skeptical but not for long. A little massage of the neck produced a real live maggot and there was no room for doubt as to where it came from. The skin about the opening was practically normal and the opening so small that it was hard to locate after the maggot emerged. But the maggot found it readily enough. Knowing the family not to be very clean in their habits I thought nothing much of the cause, but I was stumped what to do for treatment. A 95 per cent alcohol bath seemed to agree with the wiggler to perfection. I tried all the antiseptic lotions I had with me, all to no avail. Then I recalled, as a boy, I had seen my father pour some turpentine into a maggot infested wound in the leg of one of our cows. With a cotton swab I painted a bit of turpentine on the skin about the hole and to my great amazement, maggots immediately emerged as fast as they could until eight husky maggots, about 1 cm. long, hustled away from their home with no attempt to return. The maggots were white with black heads and segmented. The remedy proved effective in one application.

My second experience with maggots came three years ago when I was called by the sheriff to see a prisoner in jail. The man had been picked up by the police while sleeping in the railway yards. Too much alcohol had made him dead to the world for several hours. It was summer and a hot sun had brought many flies to him. He had complained persistently that he had "crawlers" in his ear and they were killing him. On arrival, inspection was sufficient to convince me that maggots in numbers had invaded his ear, as frequently one would come to view at the external opening. The jailor had turpentine on hand. Two drops produced complete evacuation of the maggot home in the ear. Swabbing completed the cure.

After reading the article in Minnesota Medicine I recalled an experience that came to me when, as a cowboy, one afternoon I chanced to sit down close to a clump of recent discharge from one of the animal's bowels. A gray fly, a bit larger than a housefly, lit on the heap and after a few restless wiggles of her rump a small maggot emerged from her "distal end," much to my amusement and amazement. Then came another and another and still another, until eight or ten had thus emerged to disappear on the soft mass of droppings.

Thus endeth my tale of the maggots. Will any one duplicate it?

G. H. Luedtke,
Fairmont, Minn.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
W. F. Braasch, M.D., Chairman

SURVEY INVITATION—PENNSYLVANIA

Re personal complaint of lack of medical care:

The Pennsylvania State Medical Society is one of the most active in the country in pushing its own state Survey of Medical Facilities, under the guidance of the State Secretary, Dr. Walter Donaldson.

An interesting move designed to bring to light any public complaint against doctors, hospitals and medical care has been taken by Chairman Frederick M. Jacobs of the Committee on Public Relations of the society with the approval of the society's Committee on Medical Economics in charge of the Survey.

Pennsylvania newspapers are to be asked by the doctors to publish a public invitation from the local county medical society to register with the secretary or other representative of the society any complaint anyone may have concerning medical care.

Says Doctor Jacobs in a recent issue of the *Pittsburgh Medical Bulletin:*

". . . . We urge you to contact the editors of all newspapers in your county—daily and weekly—asking them to publish your county medical society's invitation to anyone in your county to register with the secretary or other representatives of your county society the fact that he or she is NOT receiving medical care.

"The American Medical Association and your state medical society have, for many years, endeavored to reply to individual communications from such individuals, but for the first time this invitation is to be brought through the newspapers urgently to the attention of the people in each county.

"Your earnest support of this, our own endeavor, to uncover facts and to institute corrective measures is solicited."

Secretaries of Minnesota societies might consider this matter carefully with a view to the advisability of adopting it in Minnesota.

MEDICINE ON THE MARCH

When the Minnesota State Medical Association brought to a close its eighty-fifth annual meeting in Duluth, July 1, some 1,500 doctors in Minnesota held a clearer conception than ever before of the peculiar problems and responsibilities that belong to the physician alone in the social readjustments of our time.

Probably there was never a meeting of the association at which the responsibility for leadership in public health and social problems was so frequently and so definitely pointed out, even in the scientific sessions.

The clear cut conclusion is that Minnesota physicians are on the march toward a practical, well considered public policy and that they are prepared to act in accordance with this policy as leaders in community effort to improve the distribution of medical care to all the people in each community wherever, as public spirited men, they see the need for such improvements.

Need for Medical Leadership

There was a time, perhaps, when the text of typical exhorters at the economics sessions and the House of Delegates' sessions of most medical meetings was jingoistic. An enemy with a deep animosity to the medical profession was abroad in the land; we must fight the enemy. When we had vanquished the foe, sometimes called the social worker, sometimes the Foundations—why then we should have preserved intact the house of medicine and nothing further need be done. There was truth in much of what the exhorters had to say; but soberer statesmen of medicine know that it is not enough for medicine to defend itself against unjust criticism. There is a definite need for leadership in the social adjustments of the times. If medical men do not supply that leadership insofar, at least, as these adjustments involve the prevention and control of disease and the care of the sick, then America will inevitably flounder through a costly

and futile period of ill-judged social experiment in the course of which our cherished leadership in medicine may be lost for many years.

Problem Complex

To go out and fight a known and ticketed enemy is a simple matter. The problem of the doctor is much broader and more complex than that. The profession of medicine now looks behind and beyond its critics knowing that their vituperations are of no moment so long as medical men are awake to their public job and honestly at work at it.

In their careful study of the relief problem in Minnesota; in their active coöperation with relief and welfare officials to provide adequate medical care without sacrifice of standards to the needy; in their current extensive study of medical needs and supply in every community of the state, leaders of the Minnesota State Medical Association showed, at this meeting, that they are assuming this broader responsibility. They are not fighting critics; they are doing their utmost to see that the people of Minnesota have the benefit of the best that medicine has to offer. They are clearly conscious that as physicians they must keep clear before legislators and welfare officials the relation that poverty and a low standard of living bears to disease.

New Officers

Administrative responsibility for the conduct of medical association affairs will shortly rest in new hands, though only one new name is added to the roster of councilors.

Dr. George Earl of St. Paul is president-elect of the association and in line to succeed Dr. J. M. Hayes of Minneapolis as president in January, 1939. In his place as councilor of the fifth district, the House of Delegates elected Dr. E. Mendelssohn Jones of St. Paul.

Dr. B. B. Souster of St. Paul will succeed Dr. E. A. Meyerding of St. Paul, whose resignation as secretary of the organization was accepted by the delegates.

First Service Award

A report of fourteen notable years in medical organization history in Minnesota was submitted with the resignation of Doctor Meyerding and the Council voted unanimously to present him with the first distinguished service award ever bestowed upon any member for his services to the organization. This award will be bestowed, in the future, upon other members judged worthy of the honor by the Council of the organization.

It is fitting that the first award should go to Doctor Meyerding, whose service as secretary and executive secretary contributed so largely to the establishment of the Minnesota State Medical Association in its present high standing among the medical societies of the country.

The active administration of the state office of the association will remain in the capable hands of Mr. R. R. Rosell, executive secretary since leave of absence was granted to Doctor Meyerding last September. As formerly, he will carry on his work under the direction of the Council and officers of the association and in conformity with established policies of the association.

The new vice presidents of the organization are Drs. J. C. Jacobs of Willmar and Adolph M. Hanson of Faribault. Speaker W. W. Will of Bertha was reëlected; Doctor Meyerding will serve as vice speaker.

Dr. W. H. Condit of Minneapolis was reelected treasurer and Drs. H. Z. Giffin, L. L. Sogge and B. S. Adams were reëlected councilors of the first, second and ninth districts, respectively.

The delegates to the American Medical Association remain as before except that Dr. Joel C. Hultkrans of Minneapolis will act as alternate for Doctor Coventry in place of Doctor Earl.

Two major addresses made at this meeting will greatly affect the thinking of many physicians in Minnesota.

Notable Addresses

One was the presidential address of Dr. J. M. Hayes of Minneapolis which sketched in terms of exact figures the immensity of the welfare and relief problem that faces Minnesota today. Also the status in general of medical participation in the handling of medical care for thousands of people—running very close to a half million—for whom some degree of care is provided.

The other was the banquet address of Dr. Howard W. Haggard, associate professor of applied physiology at the Sheffield Scientific School

at Yale, and one of the most skillful of all public speakers in the field of medicine.

Departing from Precedent

Departing from the immemorial precedent of banquet speakers, Doctor Haggard presented an original and provocative interpretation of the rôle of the doctor and of the medical scientist and of their joint sociological significance which was for many one of the memorable high-points of the meeting. Seen in Doctor Haggard's perspective of 3000 years or more, the fundamental cause of today's social maladjustment is in the increase in the span of human life, an increase sufficient to change the character of the population and its problems. And it is not the medical scientist, the researcher, who will successfully re-align this new population group in the social scheme of things; it is the real practitioner of medicine, the family doctor who is the personal adviser of his patients and at the same time the leader in his community.

The address embraced a grave warning that caught universal attention against a system of medical education which seeks to make a laboratory man of every graduate and also against the consequences of substituting scientists for true physicians in the practice of medicine.

The complete paper will be printed in full in Minnesota Medicine. Watch for it!

Other talks of real significance to the economic and social situation of the professions were given by Chief Justice Henry M. Gallagher of the Supreme Court of Minnesota and Mr. Stanley B. Houck, chairman of the American Bar Association's Committee on Unauthorized Practice of Law. Both of these addresses, likewise, will be printed in full and will surely be read with interest by everybody in Minnesota.

Survey Results

Certain committee reports deserve comment and quotation in advance of the printing of proceedings of the House of Delegates.

The progress of the Survey of Medical Care, for instance, was a matter of general concern.

Dr. W. F. Braasch, who presented the report of the national survey at San Francisco a short time ago, also presented data on progress in Minnesota.

Form No. 1 covering actual experience of individual doctors in their practice has been sent to every member through the secretaries of county and district societies.

Form No. 2 on hospital facilities and activities is in charge of Mr. A. M. Calvin, secretary of the Minnesota Hospital Association. Forms have been sent to all of the members of the association and we understand that a satisfactory return is coming in.

Form No. 3 is concerned with nursing in general. To secure the information required concerning public health nursing, forms were sent to all public health nurses under the jurisdiction of Miss Olivia Peterson, director of public health nursing for the Minnesota State Department of Health. Returns were reported from 35 counties this week by Miss Peterson's office. (It will be remembered that only a limited number of counties support public health nurses.) To secure information concerning private duty nurses, forms were sent out by the Minnesota Registered Nurses Association to the nine districts of the organization. To date, the information has been received from four districts.

Form No. 4 on official public health activities is in the charge of Dr. A. J. Chesley, executive officer and secretary of the State Board of Health and member of the American Medical Association's advisory committee on the Survey, who sent it to all community and county health officers in the state. To date returns have been received from 68 counties and 7 communities.

Form No. 5 on public welfare activities is in the charge of officials of the State Relief Agency, who have sent the form to relief workers in every county. To date 65 counties have returned properly filled in forms.

Form No. 6 on health activities in the schools is in charge of the State Department of Education for the public schools. To date 80 per cent of city and town schools and all county superintendents of the state have returned their forms. Forms were sent direct from the state office to the 300 parochial schools in the state and of these 150 have already been returned.

Form No. 7 on health services in the colleges went from the state office to the 25 colleges and universities of the state. Of these 22 have been properly filled and returned.

Form No. 8 concerning medical services arranged for or provided by industrial, fraternal, mutual benefit, group hospitalization, community

health and other similar organizations or by the county medical society is being handled direct by the state office.

Form No. 9 on activities and experience of wholesale and retail druggists was received at a much later date than the other forms. The forms are now in the hands of the state pharmaceutical association, however, and are being distributed by districts all over the state. Group meetings are being held by the association in the various districts for the purpose of stimulating interest among members and securing accurate information.

Returns from Physicians

Said Doctor Braasch:

"No comprehensive information is available as yet as to the progress made by county and district medical society secretaries in securing the information on Form No. 1 from the individual doctors.

"The return is close to one hundred per cent in some counties. In others, forms are coming in slowly. Your committee would ask that every delegate here take it upon himself to see that the survey is carried out in his county as completely and as rapidly as possible.

"Without doubt, the information asked for in Form No. 1 is the crux of the Survey, and other data, no matter how comprehensive, cannot be evaluated properly without the testimony of the doctors themselves. It is of greatest importance that questions No. 7 and 9 be answered. It is of fundamental importance to know what the practitioner thinks about methods for improving the distribution of medical care.

"The forms were sent to the secretaries of the local societies and are to be returned to them and a special appeal to all members who have not yet made their returns should be made at this meeting.

Accurate Estimates Will Serve

"The committee in charge appreciates the fact that exact information may not be available in all cases and for all questions. In general, however, an appropriate estimate is possible and will serve to answer the questions. **It has been suggested that an accurate record of the number of charity patients and other specific data be made for a definite period as a check on the estimates furnished. The American Medical Association will soon forward blanks for this purpose. These blanks are to be filled out during a period of one week during two or three specific months of the ensuing year. They will soon be distributed by the state secretary.**

"The physicians' forms are to be sent unsigned to the local secretary and he, in turn, with the assistance, if necessary, of the state office will tabulate them on a form provided by the American Medical Association. The original forms returned by the physicians will remain in the possession of the local societies concerned.

Not a Statistical Exercise

"It goes without saying that the Survey will be of small value either as a picture of conditions in Minnesota or as a basis on which to build improvements and readjustments where they are needed unless the information secured is representative of all districts and classes.

"This effort is not a statistical exercise but an honest attempt to evaluate our medical service in every county in Minnesota. As such, it is of personal importance to every physician. Upon the accuracy and honesty with which it is carried on may well depend the future of medical practice in Minnesota."

Public Health Committee

Public health education is the greatest problem that faces the doctor today, Dr. L. R. Critchfield, chairman of the Committee on Public Health Education, told the House of Delegates in the annual report of his committee.

It is the crux of much of our economic and social difficulty and the foundation for good medical care.

According to this report, people in the low income groups who fail to get good care, go uncared for, often, because they did not know how or where to go for help; or because they did not know the importance of getting help before their trouble progressed to a stage where medical care was unavailing.

This interpretation of the problem facing physicians prefaced an appeal to the individual practitioner of medicine all over Minnesota, not only to be alert to every accepted means of disease prevention and control but to be a teacher of good hygiene to the general public and also to be thoroughly informed as individuals on every community resource for helping the unfortunate.

"When the neglected illness is thoroughly investigated," Doctor Critchfield said, "it usually develops that ignorance and carelessness and not actual absence of medical facilities was the cause of the neglect.

"The conclusion seems to be inescapable that public health education is the fundamental health need in this country rather than federal subsidies to physicians or new laws and new taxes.

"It becames increasingly clear to members of this committee that it is the doctors and not the nurses, social workers or lay health agencies who must assume the responsibility for direction of this work. A concentration upon a more extensive and far-reach-

ing program of public health education should be a cardinal objective in our program for better medical care for all the people in Minnesota; but this program must not be delegated to a single committee or group. It must be the individual responsibility of every practicing physician in the state."

Low Income and Indigent Problems

Dr. W. A. Coventry of Duluth, chairman of the Committee on Low Income and Indigent Problems, concurred in the above recommendation as one of the fundamentals of meeting the problem of care for the sick poor in the report for his committee.

"The United States leads the world in emphasis on prevention of disease," he said. "But even the United States has taken only the first steps in preventive medicine.

"The ultimate objective of all our efforts should be to lessen sickness rather than to lower costs of medical care.

"At the same time, physicians, knowing well the burden placed upon people of small income in time of illness, are morally and socially bound to coöperate with the proper authorities to the fullest extent so that competent care can be made available to all who need it."

The Doctor's Side

Delegates were urged by Doctor Coventry to do their part toward making the nation-wide study of medical facilities (reported above by Doctor Braasch) accurate and representative.

"Many surveys of medical care have been conducted by government and private lay agencies," he said. "It is well for us to have their side of the story; but, as in all stories, there is another side. And this side, which is the doctor's side, is absolutely essential to an accurate evaluation of needs.

"The medical profession will never oppose any adjustment of our system that careful studies may show to be necessary for the good of all. The doctors will insist, however, that government agencies shall not be in complete control of services that cannot be administered properly except by trained medical men. They will also insist that the sick man be allowed to apply to his own physician when he seeks medical aid."

Praise for State Officials

Resolutions of appreciation to officials of the State Board of Control and the State Relief Administration for their sound handling of medical phases of welfare and relief work in Minnesota were passed by the delegates at their Tuesday night session.

A résumé of the participation of the state medical association in framing plans for care of the needy in the state was given to the delegates in the report of R. R. Rosell, executive secretary of the association. Mr. Rosell's report included warm praise for the readiness of state officials in all departments to coöperate closely with the doctors in order that the best possible service may be given to relief clients and recipients of assistance aids.

Marked Gains This Year

"Definite and marked gains have been made during the past year," Mr. Rosell said, "in the firm establishment among all official welfare agencies of accepted medical procedures in the care of the sick.

"Fundamental to all of them was the inclusion in the Extra Session Laws of 1937 of the 'choice of vendor clause' which guarantees to the relief patient the right to select his own physician.

"Equally important was the ruling of the Attorney General on the clause which establishes this right."

The obligation upon the individual physician, particularly in the rural districts, to know all of the official sources of aid for needy patients was reiterated by Mr. Rosell in his report.

"The doctor's individual relationship to the community appears to have changed considerably during the last ten years," he pointed out. "It is generally agreed, now, that it is as much a part of medical practice to know how to direct needy patients as it is to know how to treat them medically. It is obvious, also, that the physician who is thus informed will be able to lay his finger upon weak spots when they present themselves and take the lead in his community in correcting the difficulty" . . .

"The result of the confidence and mutual understanding which characterizes all of our relations with official agencies, is that no hasty proposals for state supported sickness insurance or politically inspired reforms have emanated from any of the leaders in politics or welfare in Minnesota. Such alternatives have been relinquished altogether in favor of an honest attempt to deal with medical problems fairly and realistically and with no motive except the public good."

* * *

Recommendations made by the scientific committees of the organization and accepted by the delegates were noticeably framed upon public interest and public welfare.

For Better Handling of Fractures

The Committee on Fractures of which Dr. O. W. Yoerg of Minneapolis is chairman urged the appointement of a special committee in each county to study methods of first aid and transportation of accident cases in their own counties.

The adoption of standard splints for handling of fracture cases all over the state was asked also, and a public education campaign to eliminate the damage done by untrained bystanders who are first at the scene of an accident.

Reducing Asphyxial Deaths

The Committee on Asphyxia and Asphyxial Death, of which Dr. A. E. Cardle of Minneapolis is chairman, asked the especial interest of the association in reduction of the mounting death and disability rate from gas poisoning. The increasing use of automobiles and of gas in the home has brought asphyxia into the domain of everyday medical practice according to this committee. Special studies, on the one hand, and a special public campaign of caution, on the other, are necessary to handle the situation.

Insulin Substitutes

A special effort to acquaint the public of the danger of nostrums as substitutes for insulin in the treatment of diabetes was specially urged by the Committee on Diabetes, of which Dr. H. B. Sweetser, Jr., of Minneapolis is chairman. Two other projects received the sanction of the delegates: one is an effort to secure employment from relief funds of a dietitian or nurse dietitian to help in the instruction of relief patients who are receiving insulin; the other is a study to determine the attitude of industry in general toward employable diabetics, looking to better employment arrangements for otherwise normal people who suffer from diabetes.

The Child Who Does Not Hear Well

The need of concerted effort on the part of the physicians, the State Board of Health and the State Department of Education to find and help the child who does not hear well at school was brought to the attention of the delegates once more by the Committee on Deafness Prevention and Amelioration, of which Dr. Horace Newhart of Minneapolis is chairman. Every city having a population of 2,000 or more should own its own equipment for testing hearing, in the opinion of the committee.

Praise for Minnesota

Praise for the program of venereal disease control carried on in Minnesota by the State Board of Health was voiced by the Committee on Syphilis and Social Diseases before the delegates.

Minnesota's program is one of the best established and most thoroughgoing in the United States and there is no immediate need for expansion according to Dr. S. E. Sweitzer, Minneapolis, chairman.

There is danger, however, that the widespread campaign of publicity about syphilis and gonorrhea may be exploited by fakers and commercial opportunists. A recent questionable promotion in Minneapolis is a case in point (see "Social Hygiene Institute" elsewhere in these columns).

Cancer Campaign

Every member of the association should be informed on the objective and organization of the Women's Field Army which is working closely with the Committee on Cancer, of which Dr. Martin Nordland of Minneapolis is chairman. Every member should be ready, according to the report of the committee, to assist in the educational program of the Field Army. Each society should have a regularly constituted and trained speakers bureau on the subject of cancer.

Cancer control lies largely in the hands of the individual patient and his physician and the effort of the Field Army to bring people early to their physicians should have the closest assistance, in the opinion of the committee, from the physicians themselves.

Military Affairs

Among other recommendations made by the Committee on Military Affairs, of which Dr. F. L. Smith of Rochester is chairman, was the appeal to all medical reserve officers to participate as frequently as possible in army maneuvers.

The military committee also urged extension of opportunities to flight surgeons for observation of pilots under flying conditions. A recent war department ruling grounded all but five of the 285 flight surgeons in the regular army and the ruling is likely to prove a decided handicap to adequate examination, according to the committee.

SOCIAL HYGIENE INSTITUTE

A new lay educational organization was formed in Minneapolis last spring to promote a

program of venereal disease education in Minnesota.

This organization was incorporated under the name of the Minnesota Social Hygiene Institute as the first step. Then an elaborate program, including a "five year plan" for public health education on syphilis and gonorrhea and vague future legislative activity, was drawn up and the backers were ready to go to prominent citizens for subscriptions and backing.

With the widespread educational campaign on venereal diseases sponsored by Surgeon General Thomas Parran in mind, and with the impressive program of the Minnesota State Board of Health under the able direction of Dr. A. J. Chesley before them, many prominent persons were easily persuaded to lend their names to the undertaking.

To date one public meeting of the organization has been held. This was in Mayor Leach's office on June 6 and prior to the meeting several prominent persons had already withdrawn their names from this organization.

Inadequate Medical Advice

The reason was that nowhere in this birth of a promotion had the medical advice been obtained of those persons who for many years have specialized in this field.

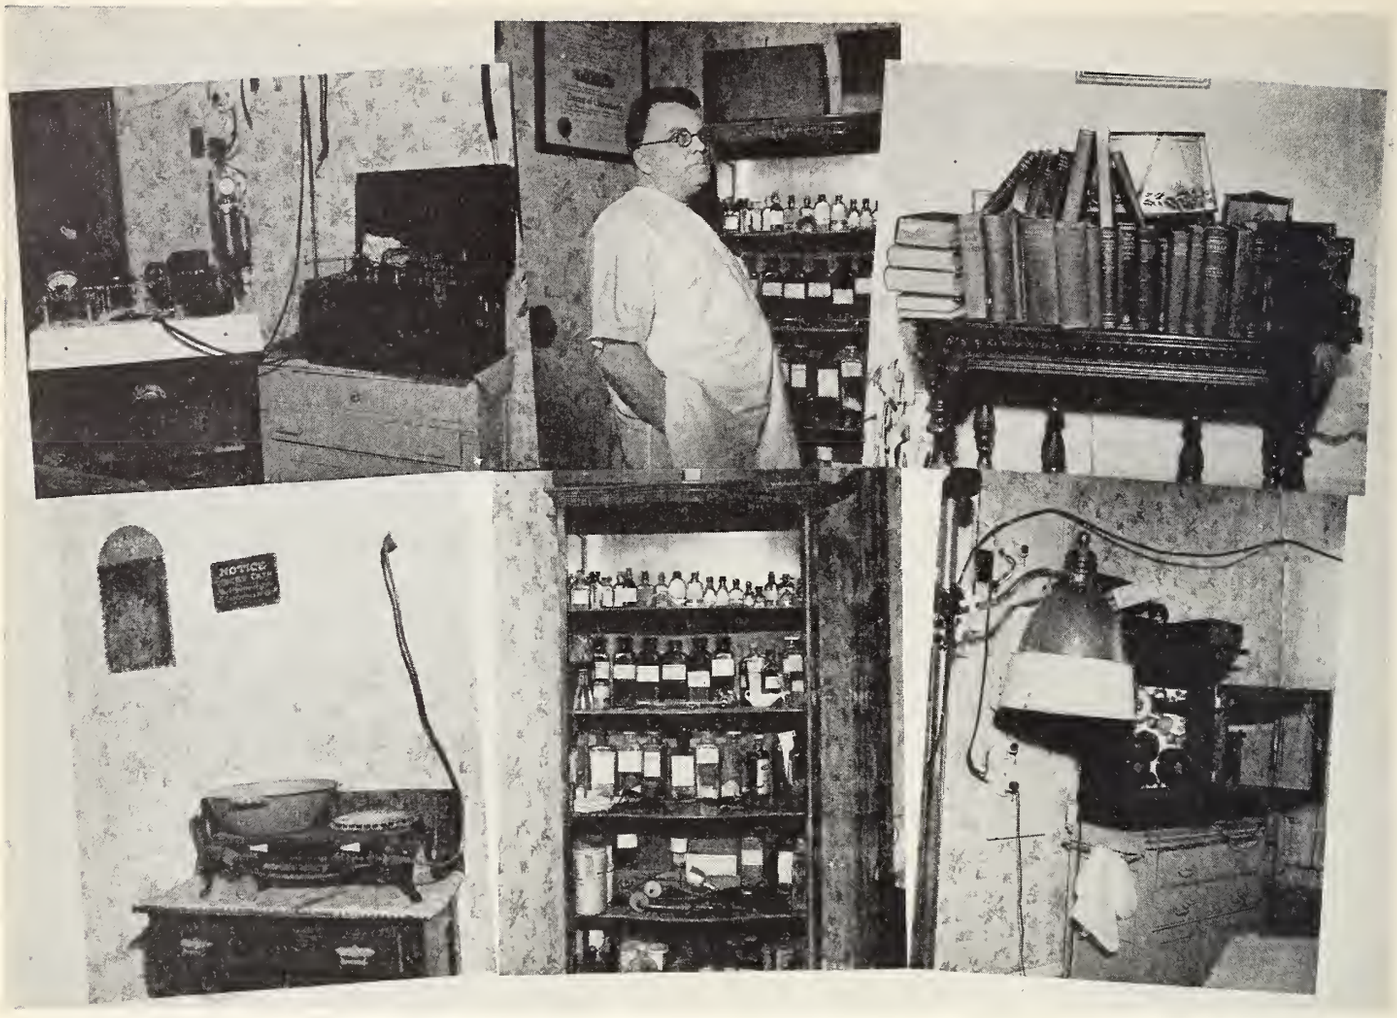
At no time had any of the constituted health authorities been consulted as to the need for the organization in the first place or as to its conduct and printed material.

The objects of the organization as outlined in letters seeking prominent sponsorship were stated as follows: to secure and supply reliable information regarding social diseases; to disseminate such information both to its members and the public; to aid in bringing knowledge regarding health and disease to the citizens of Minnesota.

When at length the health authorities and the physicians were informed about the matter, they pointed out to the backers and to potential subscribers who inquired, first, that there was an inadequacy of responsible medical leadership in the new organization; second, that a sound, well established and vigorous campaign for venereal disease control has already been in operation under the State Department of Health for many years; third, that the American Social Hygiene Association, an old, authorized and medically approved organization for public education is thoroughly qualified to provide any additional public education on venereal disease that may be necessary. There is, therefore, no need for any new organization. As a result, the Institute has been refused approval by the Minneapolis Civic and Commerce Association. Needless to say, the Minnesota Social Hygiene Institute does not have the endorsement of the Minnesota State Medical Association.

LAWS OF EXISTENCE

(Monthly editorial prepared by the Medical Advisory Committee.)



That man in intelligence is a higher order of animal than the so-called lower mammal easily accounts for the fact that he is not only controlled by the laws of nature but is subject to the laws of economics, and one of his chief concerns, as well as most perplexing problems, is to adapt himself to the changes in economic laws after he has recognized them.

The higher the degree of brain development, the more the individual is subject to economic laws and the more influence he should exert in their control. We as doctors have a deep-seated obligation to those among whom we work, as well as a profound responsibility to our confreres, and we should acknowledge our duty one to the other.

Any one who has attended recent medical meetings and noted the deep, sincere and thoughtful attitude of the discussions and the general concern evidenced in our economic problems, as they affect the medical profession as a whole, must return to his home with a desire to know more of these changing times as they affect not only himself, as an individual, but each person whether a practitioner of medicine or not.

The laws of nature center around the survival of the fittest. Petty bickerings, misunderstandings, misrepresentations of facts and quarrels ending in malpractice suits are but the urge of our lower animal instincts and should be beneath the dignity of the members of our Association.

To the thinking man in this world of change, the greatest sport is the Game of Life. Play it in such a way that you will increase, not destroy, your faith in humanity, or humanity's interest in the good works and progress of medicine.

"Dr." Frank Dahlman and Views of His Equipment

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Minneapolis Naturopath Pays $200.00 Fine

Re: State of Minnesota *vs.* Frank Dahlman

"Dr." Frank Dahlman, sixty-three years of age, entered a plea of guilty on July 7, 1938, before the Honorable Levi M. Hall, Judge of the District Court, of Hennepin County, to an information charging him with practicing healing without a basic science certificate. Judge Hall ordered the defendant to pay a fine of $200.00 or serve six months in the Minneapolis Work House. Dahlman elected to pay the fine and Judge Hall ordered it deducted from his cash bail.

Dahlman was arrested on June 18, 1938, following an investigation that disclosed he was maintaining an office in his home at 2507 Emerson Ave. N., Minneapolis. Although Dahlman holds no license to practice any form of healing in the State of Minnesota, he represented himself to the public as a naturopath. On the walls in his office he had a diploma from the so-called American University, Chicago, Illinois, dated January 21, 1920, conferring upon Dahlman the degree of Doctor of Chiropractic. Dahlman stated, at the time of his arrest, that he did not attend this school and that he received the diploma by mail on the payment of $50.00. He also had a diploma from the Kellberg Institute in Chicago, in massage and hydro-therapeutics. This diploma is dated April 27, 1920. He had a certificate from the National College of Obstetrics and Midwifery in Chicago, dated June 2, 1924. In addition to a membership certificate in the Minnesota Naturopathic Association, he also had a postgraduate certificate from the Minneapolis College of Naturopathy, dated December 27, 1928. Prior to entering the field of healing, Dahlman had worked at one of the flour mills in Minneapolis; he also had been employed as a tailor. At the time of his arrest Dahlman had, in his office, medicine bottles that would contain, when full, approximately 40,000 tablets of medicine; he had on his person the sum of $1,042.00 in cash. He stated that he had no confidence in banks, which caused him to keep such a large sum of money in his home. The investigation disclosed that many of Dahlman's patients came from Shakopee, Chaska, Carver and Norwood, Minnesota, in addition to a few from Frederic, Wisconsin.

On various occasions Dahlman had represented himself to the public as a chiropractor, chiropodist, electropath, masseur and naturopath. In 1927 he obtained a massage license from the old Minnesota Massage Board but did not renew this license in 1929 when the masseurs were placed under the Minnesota State Board of Medical Examiners. Dahlman, at one time, was chairman of the Membership Committee of the Minnesota Naturopathic Association.

Very fine coöperation was received in this case from Ed J. Goff, County Attorney, his assistant, Mr. Peter S. Neilson, and the Minneapolis Police Department.

License of Minneapolis Physician Suspended for Three Months

In the Matter of the Revocation of the License of Lewis Van Deboget, M.D.

The license of Lewis Van Deboget, M.D., Minneapolis, was suspended by the Minnesota State Board

of Medical Examiners on July 16, 1938, for a period of three months. Dr. Van Deboget was charged with "immoral, dishonorable and unprofessional conduct," and particularly with the fraudulent issuance of over 4,000 prescriptions during January, February, March and April, 1938, all of the prescriptions calling for alcohol, whiskey, brandy, gin or wine.

This is the first license suspended by the Medical Board for violation of the liquor laws of this state. In the past, the Medical Board has reprimanded the physicians and has given publicity to that fact. However, there are still a number of physicians who apparently have little or no realization of why their medical licenses were issued to them. The Board hopes that it will not be necessary to discipline other physicians, and the Board also wishes to state that unless this unlawful practice stops, a permanent revocation of the medical license will be ordered.

Saint Paul Physician's License Suspended for Two Years

In the Matter of the Revocation of the License of Nels G. Mortensen, M.D.

The Minnesota State Board of Medical Examiners, at its regular meeting held on July 16, 1938, suspended, for two years, the license to practice medicine held by Nels G. Mortensen, M.D., Saint Paul. Dr. Mortensen was found guilty by the Board of "immoral, dishonorable and unprofessional conduct," and specifically with "procuring, aiding and abetting a criminal abortion."

In Memoriam

Dr. Henry A. Schneider

1875-1938

DR. H. A. SCHNEIDER, who formerly practiced at Jordan, Minnesota, but who had been making his home since the fall of 1934 with his sister, Mrs. F. A. Rosenthal, in Owatonna, died May 7, 1938, from a heart affliction.

Dr. Schneider was born July 25, 1875, in Baden, Germany, and came to this country as a boy in 1881 with his mother and sister, settling on a farm near Deerfield, Minnesota.

Graduating from Pillsbury Academy in 1896, he attended the University of Minnesota, receiving his M.D. in 1901. After a year's practice in Stillwater, he entered a partnership with Dr. James at Jordan, which continued for twenty years. Dr. Schneider continued to practice alone in Jordan for another thirteen years, when he retired and moved to Owatonna.

It had been the practice of Dr. Schneider to spend part of each winter in Florida, but this winter he spent at Laredo, Texas. He had returned to Owatonna about a month before his death.

Dr. Schneider was always very active in the Masonic Order. He leaves, besides many friends, a sister, Mrs. Fred Rosenthal of Owatonna, several nephews and nieces.

OF GENERAL INTEREST

Dr. A. J. Button, formerly of Pine River, has opened an office at Walker.

* * *

Dr. Willard Akins of Eveleth was recently married to Miss Lila Koivisto.

* * *

Dr. A. R. Ellingson of Detroit Lakes has been appointed county coroner.

* * *

Dr. Earl Ellis of Elgin was recently married to Miss Marvel Magner of Shafer.

* * *

Dr. George J. Halladay has opened an office at Brainerd for the practice of medicine.

* * *

Dr. M. P. Virnig, of Wells, was married on June 20 to Miss Genevieve Kelly of Minneapolis.

* * *

Dr. L. N. Casmey, formerly at Moorhead, has located in Crookston for the practice of medicine.

* * *

Dr. Clifford Wadd of Waseca has become associated with Dr. O. J. Swenson in the practice of medicine.

* * *

Dr. S. J. Raltz, formerly of Racine, Wisconsin, has become associated with Dr. F. T. Brigham of Watkins.

* * *

Dr. Arthur Ecker of Rochester was awarded an M.S. degree in neurology from the University of Minnesota in July.

* * *

Dr. A. A. Giroux, formerly of Duluth, has been appointed Assistant Physician at the new Moose Lake State Hospital.

* * *

Dr. John E. Boysen, son of Dr. Peter Boysen, has opened an office in Pelican Rapids, his home town, for the practice of medicine.

* * *

Dr. Marie K. Bepko has opened offices in Cloquet for the practice of medicine. She is associated with her husband, Dr. R. H. Puumala.

* * *

Dr. Carl Coombs, a graduate of the University of Minnesota, has recently become the assistant of Dr. R. C. Radabaugh at Hastings.

* * *

Dr. D. Howard Rolig, formerly at the Ancker Hospital, Saint Paul, has taken over the practice of Dr. L. J. Hoyer at Howard Lake.

* * *

Dr. Carl H. Mattson, formerly of the Olson Clinic, Duluth, has returned to Saint Paul, with offices at 411 Lowry Medical Arts Building.

Dr. Baldwin Borreson, Superintendent of Oakland Park Sanatorium at Thief River Falls, was recently elected president of the Rotary Club.

* * *

Dr. G. H. Adkins, formerly of Grygla, has purchased the St. Matthew Hospital at Pine River, which was formerly operated by Dr. A. J. Button.

* * *

Dr. Byron Cochran of Saint Paul has joined the staff at the Rood Hospital at Coleraine. Dr. Cochran was formerly at the Miller Hospital in Saint Paul.

* * *

Dr. A. A. Schmitz, who has just completed an internship at the Minneapolis General Hospital, is now associated with Dr. E. G. Nethercott of Pine City.

* * *

Dr. V. D. Thysell of Hawley and Miss Nanette Abt of Minneapolis, were married in June. After an eastern trip, Dr. and Mrs. Thysell are now at home in Hawley.

* * *

Dr. Frank A. Grawn of Northome, formerly of Duluth, has retired after 42 years of practice and left for Traverse City, Michigan, where he will establish the family home.

* * *

Dr. H. J. Kurtin, formerly of Cudahy, Wisconsin, has become associated with Dr. S. T. Kucera of Lonsdale. Dr. Kurtin will also assist Dr. Kucera in the office which Dr. Kucera has opened at New Market.

* * *

Dr. and Mrs. S. Z. Kerlan have gone to California, where they expect to make their home. Dr. Kerlan, who has practiced at Aitkin, is retiring from active practice. Dr. R. A. Murray of Duluth has taken over the practice.

* * *

The Minnesota Academy of Medicine held a stag party at the country home, Rippleside, of Dr. Archa Wilcox, on July 12. Some forty members enjoyed the hospitality of their host and hostess, some indulging in cards, and all enjoying to the utmost the informal get-together.

* * *

Dr. Philip Rains Beckiord of Duluth, who was recently married to Miss Margaret McGilvray, also of Duluth, has located in Willmar for the practice of medicine. He is associated with the Willmar Clinic. Dr. Beckjord is a grandson of the late Dr. John M. Rains, a pioneer Willmar physician.

* * *

Dr. F. M. Feldman of Mankato, who has been director of the rural health district in that vicinity, will be transferred, September 1, to Rochester to organize a new district health unit there. The Rochester unit will be the third district established in Minnesota under the State Department of Health.

* * *

In our July number the statement was made that Dr. L. J. Leonard of Minneapolis is the only individual in the Northwest licensed to practice both law and medicine. Our attention has been called to the fact that another Minneapolis physician, Dr. W. K. Foster, has also been admitted to the bar. Are there any others?

* * *

Dr. and Mrs. C. G. Oeljen of Waseca sailed July 27 on the Europa for Vienna, where Dr. Oeljen expects to take a course in eye, ear, nose and throat work. Dr. Clifford Wadd, who recently became associated with Dr. O. J. Swenson of Waseca, will have charge of Dr. Oeljen's practice during the six months he will be away.

* * *

The Board of Regents of the University of Minnesota has accepted gifts from the Trustees of the Stevens Avenue Home of Minneapolis and the Commonwealth Fund of New York for the establishment and maintenance over a five-year period of a Children's Psychiatric Clinic. This Clinic will be affiliated jointly with the Department of Pediatrics and the Department of Psychiatry. Its primary purpose is to integrate the teaching of preventive psychiatry with pediatrics for senior medical students and for graduate students registered in Psychiatry and Pediatrics.

* * *

The Post Graduate Medical Institute's courses which have been offered to practicing physicians during the past two years in connection with the Center for Continuation Study, at the University of Minnesota, have evoked such enthusiastic responses on the part of physicians and have seemed to meet such a definite need that the Commonwealth Fund of New York is providing a subsidy for the further development of this program over the next five years. This will make possible a study of the need for and the effectiveness of the courses offered, and experimentation with various types of instruction. Dr. William A. O'Brien has been transferred from his other duties to the Directorship of Post Graduate Medical Education on a full-time basis.

* * *

Dr. and Mrs. A. E. Henslin, Le Roy, Minnesota, were given a testimonial dinner on June 23 at the Odd Fellows Hall in recognition of the doctor and his forty-seven years of professional service rendered the community. Mr. J. A. Schneider, acting as toastmaster, eulogized the guest of honor as a doctor and friend, and Mr. Frank Young spoke in behalf of the older generation who had known Dr. Henslin since he first came to Le Roy. Other speakers recalled the activities of the doctor as one of the organizers of the First National Bank of Le Roy, as a founder of the local telephone company, as a former mayor of Le Roy, and as a member of the school board. Others who took part in the program were Dr. M. P. Morse of Le Roy, and Dr. J. J. Morrow of Austin, who spoke of the medical progress achieved during the years Dr. Henslin had practiced in Le Roy. Most satisfying must have been the tributes paid Dr. Henslin as a fine type of general practitioner.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR AUGUST

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 9:45 o'clock every Saturday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

August 6—Trichinosis
13—Growth and Illness
20—Dyspepsia
27—Dental Disease.

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The annual meeting of the Association will be held in Washington, D. C., September 12-14, in conjunction with the Third International Goiter Conference. Members of the profession are cordially invited to attend. Dr. W. Blair Mosser, Kane, Pa., is the secretary of the organization.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The 17th annual scientific and clinical session of the American Congress of Physical Therapy will be held coöperatively with the 2nd annual convention of the American Occupational Therapy Association, September 12, 13, 14, and 15, 1938, at the Palmer House, Chicago. Preceding these sessions, the Congress will conduct an intensive instruction seminar in physical therapy for physicians and technicians—September 7, 8, 9, and 10.

The convention proper will have numerous special program features, a variety of papers and addresses, clinical conferences, round table talks, and extensive scientific and technical exhibits.

The instruction seminar should prove of unusual interest to everyone interested in the fundamentals and in the newer advances in physical therapy. The faculty will be comprised of experienced teachers and clinicians; every subject in the physical therapy field will be covered. Information concerning the convention and the instruction seminar may be obtained by addressing: The American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago.

INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION

The Twenty-third International Assembly of the Association will be held in the public auditorium of Philadelphia, October 31, November 1-4, 1938. The program will include some eighty prominent teachers and clinicians and the facilities of this large center of population will provide an abundance of clinical material. Pre- and post-assembly clinics will be held at the local hospitals on the Saturday before and that following the meeting.

Hotel reservations should be made in advance through Mr. Thomas E. Willis, Chamber of Commerce Building, 12th and Walnut Streets, Philadelphia. All members of state and provincial societies are cordially invited to attend the meeting.

Officers this year are: Dr. Elliott P. Joslin, Boston, president; Dr. George W. Crile, Cleveland, chairman of program committee; Dr. William B. Peck, Freeport, Illinois, managing director.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Northern Minnesota Medical Association will be held in Crookston on August 29 and 30.

Dr. Richard Bardon of Duluth is chairman of the program committee. A feature of this year's program will be a surgical clinic conducted by Dr. Arthur A. Zierold of Minneapolis, and a medical clinic conducted by Dr. Moses Barron of Minneapolis. Dr. E. M. Hammes of Saint Paul will speak on the newer aspects of neurology and psychiatry. Dr. E. L. Tuohy of Duluth will speak on the present status of vitamin and hormone therapy. The Mayo Clinic will be represented. Fractures, obstetrics and traumatic surgery and medical economics will be presented by men prominent in their respective fields. A complete program is being mailed to members of the profession.

The local committees have made plans for an enjoyable visit. The ladies will be entertained, golf will be played and the annual banquet will include an address by the president-elect of the State Medical Association, Dr. George A. Earl of Saint Paul.

Present officers of the Association are Dr. J. F. Norman, Crookston, president; Dr. O. W. Parker, Ely, vice president; and Dr. Clarence Jacobson, Chisholm, secretary-treasurer.

WABASHA COUNTY SOCIETY

Dr. A. J. Chesley, secretary and executive officer of the Minnesota Department of Health; Dr. R. N. Barr, epidemiologist and director of Rural Health Units; Dr. Gaylord Anderson, professor of Medicine and Public Health at the University of Minnesota; Dr. Floyd M. Feldman, district health officer for District No. 2, and Dr. Vern Irwin, superintendent of Dental Health Education, Division of Child Hygiene, State Department of Health, addressed a special meeting of the

(Continued on Page 600)

MINNEAPOLIS SURGICAL SOCIETY

Stated Meeting, Thursday, May 5, 1938

HEMANGIOMA AND ITS TREATMENT

William Peyton, M.D.

Hemangioma is rather a common lesion when considered in all of its forms, and occurs in practically every part of the body. It is unexpectedly encountered at times at operations for supposedly benign tumors. It may be easily diagnosed, or it may be very difficult to diagnose. The treatment of hemangioma will always have to be varied to suit the form and location of the lesion, but at the present time, certainly, there is no uniformity of opinion concerning the treatment of hemangioma.

Hemangiomas are classified as cavernous or capillary. The capillary type appears chiefly in the form of the port-wine stain and the hypertrophic form or the strawberry type. The cavernous type with which we are primarily concerned, in its typical form, resembles the corpora cavernosa of the penis, that is, there are large venous spaces lined with endothelium separated by connective tissue septa. These connective tissue septa are of variable thickness and the venous spaces are of variable size. It also occurs in mixed form; especially does it occur with lymphangioma and it may also occur in association with lipoma or with neurofibroma.

It is obvious that the tumor with large blood spaces and little connective tissue stroma will be most compressible and that the one with small spaces and much connective tissue or the mixed tumors will be relatively noncompressible. This is of practical importance in selecting a form of therapy to fit the individual tumor.

Cavernous hemangioma is most common in the skin and subcutaneous tissues and it is usually present at birth. Some 83 per cent are recorded as being present at birth, and another 13 per cent occur in the first three weeks of life. Usually, the diagnosis is easily made from the compressibility and from the discoloration of the skin. Cavernous hemangioma of the mucous membranes occurs most frequently about the oral cavity, where, as a rule, it is rather easily diagnosed. It occurs more rarely in the gastro-intestinal tract and in this location it is very difficult to diagnose. There have now been some forty-four cases reported and most of them have not been diagnosed before operation. The story is usually that the child from birth has had repeated gastro-intestinal hemorrhages and as a rule no other signs. Sometimes the diagnosis can be made from the history and findings. A polypoid type occurs that may give symptoms of obstruction and this type of lesion may be demonstrated on x-ray examination. X-ray may also show phleboliths within the lesion that is not polypoid in type. If the hemangioma is in the lower part of the bowel it can be visualized with the proctoscope and so diagnosed.

We have had only one experience with cavernous hemangioma of the intestinal tract and this was in a boy about fifteen years of age who had had no symptoms from birth except that he had always been weak and tired more easily than other children of his age, until some eighteen months before he entered the hospital, when he developed measles. At that time he became very pale, his hemoglobin dropped to 15 per cent and red blood cells to 900,000. Just before he entered the hospital he had a sudden collapse. All examinations, including gastro-intestinal examinations, were negative, and he was explored with the diagnosis of a Meckel's diverticulum with an ulcer at the base. At the exploration an hemangioma was found involving all of the jejunum and possibly some of the ileum.

A rather uncommon form of hemangioma is so-called sinus-pericranii, which is a hemangioma of the pericranium communicating through one or more abnormal openings with the dural sinuses. This lesion was described by Percival Pott in 1760. It was again described by Pellatan in 1810. Strohmeyer, in 1850, first called it sinus pericranii and since that time it has been known as sinus pericranii of Strohmeyer. It is a soft, fluctuant tumor mass overlying one or other of the cranial sinuses. It is compressible and the characteristic thing about it is that when some maneuver is carried out which increases the intracranial venous pressure this tumor mass becomes distended. Not infrequently, therefore, the diagnosis of meningocele is made. The diagnosis should be readily made. X-ray examination will frequently show phleboliths and it shows the abnormal openings in the skull, when aspirated blood is obtained.

Up to the present time, some eighty-five cases of sinus pericranii have been described in the literature. They may be either congenital or traumatic.

Hemangioma of muscle is a more common form of cavernous hemangioma. It may be either circumscribed or diffuse, involving other tissues, especially subcutaneous tissues, tendons and joints. In an experience with five cases that we have had, two involved the subcutaneous tissues, and probably also tendon, and two involved the knee joint. These hemangiomas of muscle have all, in our experience, occurred below thirty years of age. In the literature, 95 per cent have occurred below thirty years of age, and 42 per cent of the total group of 270, that have been reported, have occurred in the thigh. The symptoms resulting from these tumors are weakness, especially a tendency to tire easily, pain, and later functional impairment and even contracture deformities may develop. All of these symptoms have occurred in one or other of the patients that we have observed. Curiously enough, this diagnosis is rarely made before operation, only 12 per cent of the cases reported having been so diagnosed.

The treatment of hemangioma has been varied. Many of the methods tried have been discarded, some because

they were unsuitable for the type of lesion and others because they were unsound in principle. However, some successes have been reported with almost all methods. Even in most ancient times vascular tumors including hemangiomas were cauterized or excised. Other types of therapy that have been introduced in more ancient times (about 1835) were the introduction of hot needles, and of setons with threads. These methods were effective, in all probability, because they produced scar tissue. About 1845, the injecting of sclerosing solutions in the treatment of hemangioma was introduced or at least popularized by Pravez. The treatment was not limited to hemangiomas since no distinction at that time was made between hemangioma, aneurysm and arterio-venous aneurysm. All of these lesions were treated by the injection of ferric chloride solution, a caustic. Very serious complications and deaths occurred as a result of this treatment and it apparently fell into disregard after several years of popularity.

Vaccination was introduced in the treatment of hemangiomas about this time and it was revived by Friedjung in 1933. It does destroy some small superficial hemangiomatas by scar tissue formation. The injection of hot water was introduced by Wyatt in 1902 and has been used quite extensively since that time. Alcohol injections were introduced in more recent times. Gallant, in 1903, reported sixty-seven cases so treated, and in general he considered the results satisfactory. At the present time, this method is used at the General Hospital under the supervision of Dr. S. E. Sweitzer with very satisfactory results in properly selected cases. Galvanocautery, introduced by Middledorff in 1854, was soon used for the treatment of hemangioma and more recently high frequency current has been used. Figi, in 1936, considered high frequency current the preferable method of treatment for cavernous hemangioma about the face. Irradiation, of course, has been introduced in rather recent times and is satisfactory in hemangioma of the skin of children.

Excision, of course, has been utilized throughout this period and is still the favorite method of many. It is a satisfactory type of treatment in properly selected lesions, that is, well circumscribed lesions, where the resulting scar will not be disfiguring.

The injection of sclerosing solutions was revived in the treatment of hemangioma by Babcock in 1917 when he injected quinine hydrochloride and urethane. Dowling, in 1929, reported five cases treated by the injection of sclerosing solution and it is now frequently referred to as the treatment of Dowling. That the injection of sclerosing solutions is still not an accepted form of treatment by many, is evident in the literature. It is much more frequently mentioned than recommended in the treatment of hemangioma.

At the University Hospital, we began the injection of sclerosing solutions in properly selected cases in April, 1929. Since that time, I have found the records of 132 patients that have been treated by x-ray therapy, 109 of which were treated by superficial therapy, and in the traced cases (fourteen not traced), 51 per cent had excellent or good results. Twenty-three were treated by high voltage therapy and in the traced cases (three not traced) 48 per cent had excellent or good results. The records of thirty-three cases treated by the injection of sclerosing solution have been reviewed and of the traced cases 82 per cent obtained an excellent or good result. Five cases were either not traced or are still under treatment so that the end-result cannot be determined.

In mucous membranes we have treated two cases involving the tongue, both with very satisfactory results. We have had one case of sinus pericranii which was treated with the injection of sclerosing solution with a very excellent result. It might be objected that there is danger of embolism when you inject and coagulate blood spaces which directly communicate with the dural sinuses. This may be a legitimate criticism if the lesion overlies one of the more important sinuses, but in our case the sinus pericranii was over the forehead and if thrombosis had extended into the anterior part of the sagittal sinus it probably would not have produced any serious trouble. It would seem that this fear of extensive thrombosis following injection of hemangioma is much over-rated. The same objection has been raised to cauterization of hemangioma about the face but apparently no embolism has ever occurred as a result of this, at least none have been reported. In all of the injections which we have now made, perhaps 300 or 400 individual injections, I have never seen a case of extending thrombosis as a result. It is not like injecting varicose veins where you may have an extension of the thrombosis. It seems to me the reason for this is that the spaces are large and have small communications with each other. At the present time, we are having some wax reconstructions made to determine this question. Our experience with the injection treatment of hemangioma of the muscle is not great and the results have not been excellent but they have been so promising that we feel it is well worth continuing.

The technic is very simple. If the hemangioma is large, one plunges the needle into or through the blood-filled tumor and then on withdrawing the needle with suction applied one gets blood when the point of the needle is within a blood space. The spaces are then emptied if possible by elevation or pressure and the solution injected. Sodium morrhuate in amounts up to 3 c.c. is the solution used. A pressure dressing is applied. We have used this treatment both with and without pressure and do get thrombosis without pressure but the patient complains of more pain when a pressure dressing is not applied. There is a tendency to over-distention of the hemangioma immediately after the injection is made. This reaction, following some of the early injections, was rather alarming. This is now avoided by injecting smaller amounts of the solution and the application of a pressure dressing. (Slides were shown.)

Discussion

Dr. Orwood J. Campbell: While my own experience with hemangiomata has not been large, I have followed, with considerable interest, the work which Dr. Peyton has been doing with such cases at the University Dispensary. When he first told me what he was at-

tempting I thought the method was quite irrational, but I was thinking of hemangiomata as being neoplastic in nature.

The evidence, however, is strongly in favor of the view that these tumors are not neoplastic in nature but represent a persistence of an embryonic form of circulation into later life. Viewed in this light, the injection with sclerosing agents is an entirely reasonable procedure.

It is probable that the same principles hold here as in the injection of varicose veins. An adequate concentration of the sclerosing agent must be maintained in contact with the vessel intima for a sufficient period to produce damage.

Most hemangiomata lend themselves well to these conditions. Riebert has shown that the connections between hemangiomata and the normal circulation are not very plentiful and the blood velocity is not great. Dr. Peyton has pointed out how pressure applied to a hemangioma assists in accomplishing obliteration of venous spaces.

I would expect that the more generous the connections between hemangiomata and the normal circulation and the greater the blood flow through the tumor, the greater will be the difficulty in obtaining obliteration.

I want to congratulate Dr. Peyton for interesting himself in a group of cases which heretofore have been treated in rather desultory fashion and for encouraging us in the use of a method so simple and so safe.

Dr. Carl Waldron (by invitation): I haven't had very much experience with hemangiomata from the standpoint of their initial treatment, except that I have followed with great interest many of the patients that Dr. Peyton showed on the slides, in whom the face was involved. I think it is pretty well agreed that in the infants and very young children x-ray or radium therapy is probably the procedure of choice. In older individuals with involvement of the skin of the face and the lips, or of the mucous membrane of the mouth, Dr. Peyton's results are certainly much superior to many that I have seen in other parts of the country, and I see them at times at clinical meetings. I know that this method is very much simpler and more satisfactory than the repeated use of diathermy in the coagulation form even with special protected electrodes, and the patients seem to be much more comfortable and more happy about their treatment.

Quite a number of these cases, of course, have a resultant scarring or remains of connective tissue that calls for plastic surgery at a later date. In those that I have followed I feel that many times the plastic surgery is a very minor procedure. It can readily be undertaken to bring the result up from 90 per cent to the 100 per cent from a cosmetic standpoint. Many of them require the removal of but a little bit of mucous membrane to make, for instance, the vermillion border of the lip symmetrical with that of the other side.

As for the other group, the capillary forms, it is unfortunate that many of them are treated by all sorts of methods that are not satisfactory. I think it is pretty well conceded that excision with plastic restoration is the method of choice in these cases where the cosmetic appearance is such that it would interfere with the patient's happiness and ability to get along with associates and perhaps, later on, the ability to gain a satisfactory livelihood and desirable occupation. These patients are treated by different methods, depending largely upon the part of the face involved. Certain of them near the eye can be treated best by the removal of the entire lesion and the substitution of perhaps a full thickness graft, or occasionally a flap may be used. The question of matching the skin is a problem to the plastic surgeon but, after all, any kind of satisfactory skin is usually much better than the lesion. If the lesion, however, is away from the eye where there will not be so much danger of distortion, the men who are doing a great deal of plastic surgery now feel that fractional removal and stretching of the neighboring skin adjoining the lesion over a period of perhaps three, four or five years, may make a better looking ultimate result than a patch of skin from a distant part, be it brought there as a full thickness graft or as a pedicle flap.

I had occasion to see several very fine cases of this type of treatment at a recent meeting our plastic surgery group had in Texas. The width of the lesions may amount to two and one-half to three inches and more, yet, by fractional removal and resuturing at intervals of four, five or six months, in a period of two or three years it is possible to advance the skin from the neck the entire distance and have a good matching skin with a single scar line that is not at all disfiguring. This method is very painstaking; it demands a lot of coöperation on the part of the patient, a lot of massage, a lot of stretching of the skin, the use of odds and ends of elastic apparatus in connection with adhesive in order to stretch out skin, but finally the eventual result is usually more satisfactory than skin flaps brought to the area from the chest or further down from the lateral abdominal wall or a full thickness graft from the leg or the arm.

The plastic problem in some of these cases, of course, is very much complicated by the previous treatment, the type of caustic solutions that may have been used, carbon dioxide snow or the use of x-ray and radium, et cetera, but with care, usually, it can be taken care of nicely.

The case that Dr. Peyton showed of the rather massive hypertrophic type of capillary hemangioma of the face, of course, was quite a plastic problem. In a case of that extent, one has to resort to quite a massive flap from the chest or from the lateral wall of the chest and abdomen such as the thoracic-epigastric type. The forehead flap, of course, when available, is very fine. It matches well, but, on the other hand, in America the men and women do not want their forehead skin used. In Europe it is different, the surgeons use them almost everywhere they can because they feel they can tell the ladies to wear the hair down to the eyebrow level and in the men the forehead scar and the skin graft may not be at all prominent. On this side of the water, the women wear their hair way up high and they want to show their foreheads and we can't talk them into using a forehead flap even though it will match the skin texture or the color of the nose or face better than almost any other skin.

The skin from other parts of the body, of course, sometimes makes a very satisfactory match, after a period of two or three years have elapsed, but ordinarily it takes that length of time. At other times, it doesn't match; at least, a part of the area doesn't match. It may sunburn quite differently from the rest of the skin, but now we have plenty of aids in a cosmetic way in the type of powders and creams that can be used, so that variations in color really can be disguised pretty satisfactorily.

I want to again thank you for asking me to discuss this paper and I want to compliment Dr. Peyton on the simplification of the problem of many of these cases that he has been able to offer us by his careful and cautious handling of the cases he has had under his care. Thank you.

Dr. Willard White: Dr. Peyton has mentioned that these lesions may occur in any of the tissues. I wish to call attention to the fact that similar and also allied lesions may occur in bone. Hemangiomata are not so very rare in bone. A condition sometimes confused with hemangioma is hemangio-endothelioma. I recently saw an autopsy on a patient at the General Hospital in Minneapolis where this lesion occurred in the body of one of the vertebræ and had extended by pressure so

that the cord was completely destroyed. It had also extended outward into the thoracic cavity and made a very large lesion. In the discussion of this case at the General Hospital it was brought out that hemangio-endotheliomata in bone is very rare.

Dr. Kenneth Bulkley: Nothing has been said about hemorrhage in the treatment of these hemangiomata, particularly, of course, during the operative treatment. I would like to say a word in regard to those that occur in the extremities. I would also like to ask Dr. Peyton the strength of his sodium morrhuate, and also the relation, if any, of these to trauma. I had a man, just under thirty years old, who had done hard labor all of his life and who, in hitting the end of a screw driver, developed pain in his thenar eminence. Within twenty-four hours he developed a mass. When I saw him the thenar eminence was fully twice the size of the thenar eminence on the other hand. I operated on him with the diagnosis of lipoma. It turned out to be a hemangioma involving the muscles of the thenar eminence. I did the operation, of course, using a tourniquet. It was imposible, at first, to control hemorrhage. I dissected out practically the entire thenar eminence, tying off everything I could see and we controlled his hemorrhage, finally, only by packing. I left the packing in four days, gave him an anesthetic and attempted to take the packing out with just as much hemorrhage as I had originally. I finally left the packing in three weeks before I could take it out without hemorrhage. I am wondering if there is any definite established relationship between trauma and these hemangiomata.

Dr. Harvey Nelson: I would like to ask Dr. Peyton what his recommendations are in some of these smaller capillary types of hemangiomas. I have had occasion to refer some of them to the x-ray men and they advised using carbon dioxide snow rather than x-ray, saying that the x-ray doesn't affect them very much.

Dr. Cyrus Hanson (by invitation): The small hemangiomata in children do respond in a very large percentage of cases, very nicely. As the patient gets older we do not get the results with the x-ray and radium that we do in the younger people because of the tissue becoming more adult and not being as sensitive as it is at first and the blood spaces have become larger. We know, of course, that in the lymphatic type of hemangioma where the vessels are largely lymphatic in character rather than blood vessels, the response is very poor to x-ray therapy.

Dr. William T. Peyton (closing): As to the origin of hemangiomata, I think what Dr. Campbell said about their being a congenital anomaly is entirely true, although there is still considerable discussion in the literature, at least some write as though they still considered them a new growth. They are probably an anomalous development of the capillary beds that occurs early in the embryo. The extension which occurs later is either enlargement of individual spaces or opening up a new bed.

Perhaps this would be the best place to take up the question that Dr. Bulkley asked about trauma. I think that most vascular lesions which occur following trauma are not hemangiomata but are arterio-venous aneurysms, and yet it seems that occasionally a hemangioma does occur following trauma. Sinus pericranii is said to sometimes appear following trauma. It is hard to explain these unless one admits that there are abnormal vascular spaces present that are broken into and then fill, or some such explanation. I think in general that vascular lesions which follow trauma are arterio-venous. However, Dr. Bulkley's case may have been a traumatic hemangioma and I presume it was from what he has said.

This leads to the question as to how one distinguishes between arterio-venous aneurysms and hemangioma. Arterio-venous aneurysm has increased head and often growth changes due to increased circulation to the part. These hemangiomata are of normal temperature, may even be colder than normal because their circulation is not increased. Growth changes due to hemangioma, if they do occur, should result in a decrease in growth or development in the part affected. The bones of the forearm in one of our cases were demonstrated by x-ray to be smaller than normal. The most important symptoms, of course, are bruit, thrill, and pulsating veins. If any of these signs are present, it is surely an arterio-venous aneurysm. If in doubt, one can draw blood from the vein that is returning blood from the involved part and one gets an increased oxygen content in this venous blood if an arterio-venous aneurysm exists. In hemangioma the venous blood oxygen content will be normal.

Dr. Campbell mentioned the extension of the thrombosis. Our greatest difficulty in injection treatment is that we cannot get extensive thrombosis. The thrombosis is always localized and that is the reason one has to make so many injections to destroy a large lesion. Recently, I have been trying to inject two different places at one sitting, by putting the needle way through, getting one place where I can draw blood back through the needle, inject, and then draw back farther and get into another blood space.

This brings up the question asked about how you get these blood spaces. It is very easy to get into them if one is dealing with a cavernous hemangioma. All you have to do is plunge the needle in, withdrawing it until one gets blood. In a vein, on the other hand, you have to have some technic, but in this all you do is to plunge the needle through. If the spaces are very small, of the capillary forms, then it is difficult or impossible. We have not had any success with an injection that was not made within venous spaces. We have tried injecting some of the capillary type that were mentioned by Dr. Nelson, and made some interstitial injections but all we got were sloughs, not cures, and I have very little to offer in the treatment of the capillary type except x-ray therapy.

Hemangioma of the vertebræ have been described by Makrycostas[3] and by Bailey and Bucy.[1] They find that it is a more frequent lesion than is generally appreciated (on routine postmortem examination, 12 per cent). They are usually, however, small and do not give symptoms unless they grow back into the cord.

Hemangio-endothelioma which was mentioned is an entirely different lesion. It is a neoplastic lesion and most of them are radio-sensitive.

Hemorrhage is the principal cause of death in cavernous hemangioma. Bowers[2] recently reported one in the lung that caused death by hemorrhage. Fatal hemorrhages occur in the intestinal tract and even the superficial ones may rupure, and if the patient does not know how to stop it, it may cause death.

Dr. Bulkley asked about the percentage of the sodium morrhuate. We use 7 per cent.

Carbon dioxide snow was introduced by Pusey in 1907 and it is satisfactory in the destruction of these superficial lesions like the capillary ones that Dr. Nelson mentioned, except that it leaves a white scar. I think, under certain circumstances, the use of carbon dioxide snow is justifiable but I do not use it. All I know about it is what I read and see following its use by others.

LOW BACK PAIN*

R. E. Hultkrans, M.D.

For the purpose of discussion, this paper has been divided into two parts: acute back pain and chronic back pain. In view of the recent and numerous explanations of chronic and intractable back pain, noted in the literature of the past year or two, this particular paper will be limited largely to the consideration of acute back pain. Numerous attempts have been made to classify symptoms concerning the lower back. "Low Back Pain and Associated Conditions" is the name given to no less than several thousand articles between 1929 and 1938.[13] Many of these articles attempt some sort of a classification of back symptoms and advise some sort of treatment or other. This writer was surprised to find that very few of these articles went into certain fundamental considerations such as anatomy, physiology, and definitions of terms. One also notes a definite lack on the part of most authors to classify low back pain into an acute or chronic condition, a differentiation which I feel is very important.

Just what is low back pain? Magnuson[10] presents an interesting discussion of backache as follows: "From time immemorial we have been talking about backache as something to treat instead of regarding it only a symptom, sometimes only a very small portion of a complete picture which can be ascertained only by the history and in the physical examination. It is true that backache is a very frequent symptom and undoubtedly a very irritating one. We know that in acute infectious diseases, backache is one of the symptoms of which the patient complains most. Whereas, from the standpoint of the doctor, where the disease is fully developed, it is not of major importance because he knows that the backache will clear up when the condition causing it has been removed. But where there is no well developed disease to account for the complaint, the fact that this is only part of the picture may escape attention entirely."

His discussion then continues with the indication that fully 80 per cent of people with chronic pain in the back are over forty. He discusses factors of posture and weight, occupation, and the fact that perhaps physical makeup seems to give little clue as to the cause. No definite conclusions are drawn in this particular paper by Magnuson, as in most other papers, and we find that both the acute and chronic symptoms are discussed together.

These introductory remarks have been made particularly with the idea of establishing the fact that low back pain, after all, is a symptom and of itself not a pathological entity. So numerous are the classifications of low back pain as noted by this author in the review of the literature that any attempt to present them here would be quite futile and would add to the confusion which already exists concerning this subject.

Regardless of the questions concerned in acute or chronic low back pain, certain fundamental considerations are necessary before any definite conclusions can be drawn. First, let us consider some of the general anatomical structures involved, along with a discussion of certain terms commonly used. In the hope of simplifying a conception of the muscle structure in the back,[3] we may say that there is a large group made up principally of the sacrospinalis, or more commonly called the erector spinæ group, lying on each side of the spinous processes and attaching at various levels all the way up the spine. Next, we have the flat group of muscles consisting of quadratus lumborum, serratus posterior, along with the termination of the abdominal muscles which come way around into the back. In the external layer we have the trapezius in the dorsal and upper lumbar regions, and the latissimus dorsi with its lumbo-dorsal fascia making its principal attachment at its lower margin. The lumbo-dorsal fascia is somewhat quadrangular in shape and has its principal tendon insertion down over the sacrum. Both gluteal muscles exert their influence on the back through the lumbo-dorsal fascia. There are numerous smaller intrinsic muscles which may be factors in the development of back pain, but their detailed review does not appear necessary at this time. The structure and physiology of the intervertebral disc was very carefully worked out by Schmorl.[8] Space does not permit a more detailed discussion of the other structures involved. The spinal canal, of course, encloses the spinal cord and the intervertebral foramen permits exit of the spinal nerve on either side. The ligamentum flavum covers the cord posteriorly along with the laminæ and the interspinal ligament. Again, space does not permit a detailed description of the anatomy concerning the ligaments in the lower back, particularly the sacro-iliac, ilio-lumbar, and lumbo-sacral ligaments, but reference to any standard text in anatomy will give a full review of these structures.

In discussing low back pain, it seems that certain fundamental terms must be considered. A description of common terms follows:

Muscle Spasm: Muscle spasm really means an increase in muscle tone. We must consider first then muscle tone. Muscle tone normally consists of a certain state of contraction of skeletal muscles. From embryology, we learn that there is a segmental development of the musculature with a corresponding segmental division of the nervous system. The nervous system has both the somatic and splanchnic divisions allocated to each corresponding segment.[14] Normal muscle tone exists as the result of proprioceptive stimuli acting upon a spinal reflex. If the path of the reflex is interrupted, a loss of tone follows. Stimulation of this reflex produces an increase in tone or muscle spasm. Zierold[17] points out in his article on "Morphine as a Diagnostic Agent," that if the stimuli affecting the spinal reflex overwhelm the reflex, then the excessive stimuli are carried upward along the spinal thalamic tracts to the cortical centers, spreading to the sensorium. From here, conscious, purposeful, voluntary contractions of a protective nature occur and many times are falsely interpreted as true muscle spasm. Kuntz[9]

*Inaugural Thesis

describes the condition as muscle guarding or hypertension of skeletal muscles. The author suggests a new term, subconscious voluntary muscle spasm, based on the concept that the excessive stimuli affecting the sensorium undoubtedly are influenced by the subconscious mind before being transmitted through afferent motor pathways producing coördinated contraction of muscles involving an area much larger than the area from which the original stimulation occurred. The production of such strong skeletal contractions could easily explain the characteristic lay term "kink."

Pain: An article by Crohn[6] in the *American Journal of Surgery,* defines pain as follows: "Pain may be defined as a mental interpretation of some abnormal or generally harmful process taking place in the organism." He describes physical and psychic factors including, under the latter: age, sex, previous bodily fatigue, summation of repeated hurts, and to this the author would like to add race. Under psychic factors, he describes emotional instability, vagotonic disposition, psychoneurotic makeup or the opposite of these latter, phlegmatic and indolent types of individuals. The American Medical Dictionary describes pain simply in this way: "suffering or distress."

We hear much about referred pain in the discussion of back symptoms. Again, referring to Kuntz, two main types of stimuli are indicated, namely, splanchnic or those affecting organs within the body, and somatic, or those affecting the supportive structures of the body including the sensory receptors on the surface of the body. Here, again, the explanation of afferent stimuli to the cord is used. The stimuli are then carried through various tracts to the cortical centers where they are interpreted in the consciousness, as pain. If these stimuli are of sufficient degree, as they enter the cord, they may arouse an excitation in this particular region to stimulate other sensory fibers making their entrance at this level in the cord, and thereby project to the brain a stimulation, interpreted by consciousness as coming from another portion of the body; in other words, as being referred. This may seem to be a very technical discussion of the subject of pain, but it seems important in a topic of this kind.

Kuntz goes on to state that even a spastic contraction or hypertension of skeletal muscles may give rise to pain because of the stimulating effect on the sensory receptors present in the muscle tissue itself. Hence, in acute back pain, a vicious circle is established in which a certain stimulation leads to muscle guarding, or subconscious voluntary muscle spasm, and this increased contracture then adds further stimulation through the receptors in the musculature itself. Breaking up of this vicious circle must be accomplished before relief of pain is obtained.

Posture: One hears a good deal of discussion about posture in connection with low back pain. This term is very loosely used. An attempt was made by the Children's Bureau of the United States Department of Labor at Washington, D. C., in 1926, to establish certain posture standards. Reference is made to the book[16] written following the White House Conference on child health, and protection, in which the question of body mechanics and posture is gone into very thoroughly. This book is a result of the work of a large group of consultants and very worthy of review. It does not definitely establish itself as the final authority on posture, but at least makes an attempt to begin with a definite working standard.

In considering posture, we find that the center of gravity of the body is located as low as the first and second lumbar vertebra at the beginning of the lumbar curve.[7] It becomes quite evident that with the center of gravity located at this point the muscles below this area attaching to the sacrum have a tremendous leverage to overcome.

The following classification seems logical as far as acute low back pain is concerned.

Acute Back Pain, resulting from (1) trauma; (2) infection (including toxemias); (3) posture; (4) congenital defects.

Under trauma, we do not wish to include any of the injuries which affect the bony structures of the back. We wish to include only sprains, strains, contusions, overstretching of the muscle groups or individual fibers, minute tearing of tendons, ligaments, and muscle fibers, small hemorrhages and so forth.

Under infectious conditions, one has but to refer to the article on "Myofascitis" of Albee[1] in which this particular question is most ably handled except that no mention of the pathology is made. I doubt if one could find a better definition of lumbago than that given by Osler[12] in his first text book published in 1892. He says that lumbago is a form of muscular rheumatism limited to the lumbar region of the back.

Sciatic neuritis is not to be confused with sciatica, the former representing a typical neuritis, localized to the sciatic nerve, whereas a sciatica simply means pain along the course of the sciatic nerve and may be due to other causes than inflammation.

Arthritis is always a factor which must be contended with in cases of the infectious type. Numerous forms of arthritis are described, but probably the most commonly used names are osteoarthritis, atrophic arthritis, acute articular arthritis. Here, again, time does not permit an extensive discussion of a term about which volumes have been written.

Posture as a cause of back pain is open to a wide difference of opinion. The term is so commonly used, however, in practically all articles that it can scarcely be eliminated here. It is interesting to note that the survey on posture indicated that most students fall into a class of C or D, and yet after taking postural exercises over a period of two or three or four years, still show no improvement.

The last under this classification concerns congenital anomalies. Undoubtedly, congenital anomalies lead to structural weaknesses which make an individual's back with such anomalies more susceptible to strains or stresses than that of a normal person without such anomalies. Brailsford,[2] in his book on "Radiology of Bones and Joints" gives an excellent résumé of the

various types of congenital anomalies occurring in the lower back. Probably more skeletal congenital anomalies occur in this region than elsewhere in the body combined.

All of the foregoing discussion may seem rather elementary, but unless we have a common foundation from which to start, one becomes hopelessly bogged down with a mass of confusing opinion. As a result, the examination is oftentimes made without keeping in mind these certain fundamental ideas. It is difficult to improve upon the outline offered by Webb[15] for the examination of back cases. This outline may be found in "Minor Surgery" by Christopher.[5] One notices here that particular attention is paid to a careful history. One essential part which I feel has been omitted in this outline, is again, the nondivision of symptoms into the acute or chronic stage. I believe that the duration and variation of symptoms is of prime importance in the taking of a history. A diagram of bony structures of the back is furnished with these blanks with instructions to the physician, to indicate with an "X," the location of the spot indicated by the patient where the pain occurred. I feel that this is important because persistent pain in one location is more indicative of some definite pathological condition than pain which moves from one spot to another at various times during the examination or at subsequent examinations.

Another factor is often overlooked in the examination of a back case. Too often the examiner feels that a diagnosis must be made when the individual is seen first. This particular circumstance undoubtedly accounts for numerous mistaken diagnoses. At one examination, symptoms of backache may appear to be due to trauma, whereas subsequent examinations may show, definitely, that they are of an infectious or toxic origin. If you are not sure of your diagnosis do not hesitate to have the individual return for subsequent examination and further history, and a checking of the findings noted at the time of the original examination. Surprising variations may occur between two examinations, as was the experience of this particular examiner.

A man was sent in with a history of acute back pain sharply localized to the right sacro-iliac joint. He was seen by his local physician whose examination and report was thorough, and whose treatment was appropriate for a sacro-iliac sprain, on the right side. When seen by this examiner, eight weeks later, the diagnosis of the examining physician was confirmed and continued supportive treatment advised. Three months after this examination, the individual returned because his compensation had been terminated. In going over the history, he began explaining how his symptoms had improved for a while but then became worse. On this subsequent examination, his symptoms were entirely on the left side. His description of the symptoms and his response to the various tests readily indicated that he had some knowledge of the tests used for diagnosing a sacro-iliac sprain. When he was confronted with the fact at a hearing before the Industrial Commission, that his original symptoms had occurred on the right side and that his subsequent symptoms had occurred on the left side, even though he had had no other accident, he became terribly confused and was disclosed as a malingerer, quite obviously.

Another case in point was that of an individual who had a definite accident resulting in a contusion to the back, immediate disability followed, and he was treated by his local physician. As his disability stretched out, he was referred to us for treatment and after a period of eight weeks, we were unable to show any improvement in his condition. Then, an orthopedist was given an opportunity to treat him and some temporary improvement followed. His compensation was stopped and he went to the University Hospital where further examination was made. The case finally came up for a hearing and the general consensus of opinion was that the man should have a back fusion, because of findings in the lumbo-sacral joint both clinically and upon x-ray. The x-ray findings had shown no change from the time of the original examination up to a period of six months later, but did disclose evidence of an atrophic type of arthritis involving the lumbo-sacral joint. This particular individual did not wish to have any surgery done. The case was settled out of court for a sizable sum of money, and three days later one of the representatives of the insurance company saw this particular individual weaving down Washington Avenue certainly enjoying his settlement to the fullest and exhibiting no evidence of pain or disability.

It is not the purpose of this paper to present any specific type of treatment. We feel that we can make certain suggestions, however, which we have found of particular value in practical experience. Consider the patient first. What is his attitude? What is his ability to stand pain? Does he have confidence in you? If these factors are within normal limits and the examination has disclosed no evidence of any severe pathology or injury, even though some objective findings may be present, the treatment, with recovery, should be simple. Attempt to explain to the individual what has happened in his back. Allay his fear of pain and his fear of a chronic back condition. Avoid strapping or splinting of the back in acute back strains since it limits the exercise so necessary to maintain circulation, and decreases the ischemia which follows even with prolonged muscular contractions of a voluntary nature. Advise him to exercise to overcome the spasm in his back. Show him how to exercise to avoid undue straining or increased pain.

Recent preliminary work done by Caron[14] on the use of novocaine in the back appears to offer a tremendous opportunity in the handling of cases of acute back pain. Fear of pain, undoubtedly, is one of the biggest factors in the development of muscle guarding or subconscious voluntary muscle spasm. If this can be overcome in the acute case, a recovery is very prompt within a few days or not more than a few weeks.

X-ray therapy is being used with almost sensational

results in some cases, yet the x-ray therapists are unable to say why.

The second part of this paper dealing with chronic back pain will be very brief. At present, we are hearing much about a protruding or herniated intervertebral disc. Not long ago, we heard about articular facetitis. Prior to that we heard of taut ilio-tibial band and prior to that any number of other causes. Perhaps the best discussion of the situation is given by Ryerson[11] of Chicago in which he states: "Again, there is offered a solution for low back pain and sciatica. In the years in which I have been coming to these meetings, I have seen many new procedures advised and adopted. What is the reason that it is so difficult to find out the pathological conditions underlying low back pain and sciatica? Obviously, these people don't die of low back pain and sciatica. No specimens are obtained, not any scientific evidence as to what is causing these troubles except in those few who are subjected to laminectomies, and in whom the foramina of the fourth or fifth lumbar nerve is exposed, or who can be seen postmortem in rare instances after accidents or the results of intercurrent disease. We do not have a good pathologic scientific foundation for most of our work on the low back and sciatic region."

In conclusion, it seems that a tremendous number of things can happen to cause pain in the back. Perhaps our evolution from quadripeds to bipeds may have something to do with the situation. It may be that the race is deteriorating physically because of the changing social order. The author feels that a more careful observation of fundamental principles both as to examination and treatment may be of some value, but when all is said and done the actual pathology of low back pain remains largely unknown.

Discussion

Dr. R. P. Caron: The subject of low back pain, including acute and chronic back strains and industrial accidents, has been exceptionally well presented by Dr. Hultkrans. It brings to our attention all of the problems we must consider in this type of case. To my mind, so far as treatment of acute back strains is concerned, treatment comes under two important factors. First, the anatomical findings and, second, the psychological aspect of the patient. I believe that the beginning of the treatment is most important. In other words, in addition to careful history and physical examination, one must institute prompt relief, both physiologically and psychologically. For the last few years, I have used the novocaine injection treatment by injecting a one per cent novocaine solution, without adrenalin, into the most painful area, the one which usually shows most muscle spasm. In most instances within five or ten minutes relief of pain and spasm is observed. The patient, thus, gains confidence in his doctor and in himself. He is then told to bend forward and backward as far as he can. In some cases the spine is then manipulated in order to break up any muscle spasm which may persist. The patient is then advised to return home and to use external heat. The following day, the back may be reinjected if muscle spasm persists. I should like to add, however, that usually the injection and manipulation treatment is done only after x-rays have been taken, expecially in the industrial accident type of case. This type of treatment, in most instances, shortens the convalescence.

Another peculiar thing is in reference to industry. The type of industry in which the patient is employed and the compensation which he receives are definite factors in determining the period of recovery. Those who receive the least compensation return to employment sooner. This would lead one to conclude that the compensation factor has something to do with the prolonging of an acute back strain into a chronic one, that is, if there are no positive bony or neurological findings. It would appear that the employer can help a great deal by allowing the employe with an acute back strain to go to work on light duty and gradually return to regular duty rather than have him wait until he is completely well.

Dr. Wm. Peyton: I don't know just how much credit Dr. Hultkrans gives to prolapse of intervertebral disc as a cause of pain. I think that perhaps some people, at the present time, are too enthusiastic about this but I think it would be unfortunate if this group were left with the idea that there is no such thing as pain due to intervertebral disc. I have operated upon people for pain supposedly due to an intervertebral disc and I don't believe they had it, at least results were not entirely satisfactory, but I have operated upon some with very satisfactory results. I have seen intervertebral discs that were so prolapsed that a portion could just be picked out and certainly that is evidence that there is something wrong with the disc. The only reason for my making this discussion is that I wouldn't want to have the impression left that there is no such thing as pain due to intervertebral disc. Perhaps, Dr. Hultkrans didn't mean to put it so strongly, but I got the impression that he considered it a very minor cause of back pain.

One of the most difficult things for me to decide, at the present time, is when to inject lipiodol to make this diagnosis. If you do inject lipiodol, I think you can pretty definitely say that the patient has or has not prolapse of an intervertebral disc, but one does not like to fill a lot of spinal canals with lipiodol which is retained a long time. I don't know just what the indications are, at the present time. I think they are something like this, that you have a good thorough examination for every other cause of back pain, including all of the things that Dr. Hultkrans has mentioned tonight and then, if nothing is found, spinal puncture is done. If it shows increase in the protein content, that is an indication for injection of

lipiodol. On the other hand, if you do not get a change in protein content, then you still are faced with the question of whether you should or should not inject lipiodol. Some discs will be prolapsed and still you will have normal spinal fluid content. I think, if the pain is severe enough and persistent enough and you cannot find some other cause after sufficiently thorough search, then lipiodol injection is justified.

Dr. Kenneth Bulkley: What is the life history of lipiodol if it is left alone and the patient is not operated upon? Is it absorbed, and have any of these cases been traced?

Dr. William Peyton: Lipiodol in the spinal canal apparently is not absorbed. As far as one can tell from repeated examinations that have so far been made, it remains there indefinitely. Some patients do have irritation from it; many of them do not.

Dr. R. E. Hultkrans (closing): A discussion of chronic back pain was avoided purposely. I do not believe that anyone has shown that acute back pain results from a protruding disc. The Mayo Clinic reports a series of 100 cases in which spectacular results have been obtained for the relief of chronic back pain by the surgical removal of the protruding portion of the offending intervertebral disc. My feeling is that it is still too early to draw any definite conclusions concerning the work on the protruding disc. One such operation was performed in Minneapolis just recently for severe intractable pain in the dorsal region of the back, causing the patient to threaten to commit suicide. Lipiodol injections followed by x-ray revealed a definite protruding disc which was removed surgically and resulted in a complete relief of symptoms. Whether all of these cases will remain cured over a period of three or four or five years remains to be seen.

One wonders, in reviewing the literature, why there have been so many numerous types of operations advised for the relief of relatively similar symptoms. Fusions of the lumbo-sacral and sacro-iliac joint have been commonly done, cutting the ilio-tibial band, cutting the pyriformis muscle, stripping the fascia, and numerous other surgical procedures have been done and each author reports results which show over 75 per cent cures.

The pathological condition in these cases most likely remains unknown. About six years ago, I went to Dr. Bell and asked if there would be an opportunity to obtain autopsy specimens of backs. He said that there would not be, and I might just as well forget about it for two reasons. The first was, that it meant doing an autopsy other than the routine autopsy and immediately one would be open to liability for doing anything but the routine autopsy; the second was, that the undertakers would not permit it. If you take out the spine, you injure the large vessels and embalming becomes quite a problem. Schmorl's work of several years ago was a very carefully done piece of research. Fresh autopsy specimens of the entire spine were obtained and examined in various ways. He took out the nucleus pulposis and even measured the pressure within the nucleus. He described a ruptured nucleus pulposis with the rupture occuring into the bodies of the vertebra either above or below the particular disc involved. If we could obtain such autopsy material and review the findings in the light of our present surgical experience, perhaps much would be added to the picture.

As stated before, I had hoped to avoid a discussion of chronic back pain in this paper. I wish to call attention particularly to the voluntary element in the contraction of muscles occurring in acute back sprain. I wish, also, to call attention to the necessity of overcoming this element before relief of the acute symptoms can be obtained. If these acute back strains or sprains can be treated and relieved of symptoms in a short period of time, I believe that many of the chronic cases of low back pain will be prevented.

The meeting adjourned.

Harvey Nelson, M.D., *Secretary.*

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

Essentials of Obstetrical and Gynecological Pathology. Marion Douglass, M.D., F.A.C.S., Assistant Professor of Gynecology, Western Reserve University, and Robert L. Faulkner, M.D., Senior Clinical Instructor in Gynecology, Western Reserve University. 187 pages. Illus. Price, cloth, $4.75. St. Louis: C. V. Mosby Co., 1938.

Medical Writing. The Technic and the Art. Morris Fishbein, M.D., Editor of the Journal of the American Medical Association. 212 pages. Illus. Price, $1.50, flexible binding. Chicago: American Medical Association Press, 1938.

Die Therapie Der Thrombose. Dr. Ernst Friedlander. 117 pages. Illus. Price, paper cover, 5.40 K. Leipzig and Vienna: Franz Deuticke, 1938.

Standards for the Diagnosis and Treatment of Cancer. By the Executive Cancer Committee, Iowa State Medical Association. 168 pages. Price, $1.00, paper cover. Iowa City: Athens Press, 1938.

Symptoms of Visceral Disease. Fifth Edition. Francis Marion Pottenger, A.M., M.D., LL.D., F.A.C.P. Medical Director Pottenger Sanatorium & Clinic for Diseases of the Chest, Monrovia, California, Professor of Clinical Medicine University of Southern California, etc. 442 pages. Illus. Price, $5.00, cloth. St. Louis: C. V. Mosby Co., 1938.

Hernia. Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis and the Operative and Injection Treatment. Second Edition. Leigh F. Watson, M.D. Member of Attending Staff of California Lutheran Hospital and Methodist Hospital of Southern California. 591 pages. Illus. Price $7.50, cloth. St. Louis: C. V. Mosby Co., 1938.

A Challenge to Sex Censors. Theodore Schroeder. 159 pages. Privately printed in New York to promote the aims of the Free Speech League. 1938.

HEMORRHOIDS. Marion C. Pruitt, M.D. 170 pages. Illus. Price $4.00. St. Louis: C. V. Mosby, 1938.

This monograph on hemorrhoids by Dr. Pruitt is exceptionally well formulated and written. It has not been my pleasure to read a more excellent treatise on this subject.

This monograph should be readily available for any and all physicians who attempt to treat hemorrhoids. The operative detail is so well illustrated and explained that any physician can easily learn how to make hemorrhoidectomy a clean, physiologically correct operation.

I cannot praise the author too highly for his excellent treatment of this subject.

E. E. Scott.

METHODS OF TREATMENT. 6th edition. Logan Clendening, M.D., 879 pp., Illus., $10.00. C. V. Mosby Co., St. Louis, 1937.

This justly popular text, now in its sixth revision, is attractively printed, on good paper, and with large uncrowded type. Its well-known author has succeeded in introducing his characteristically informal style into the discussions, and thus makes such chapters as those on psychotherapy, and the psychoneuroses, readable and enjoyable. One is inclined to accept his attitude toward psycho-analysis with sympathetic approval.

The chapters on drugs are excellent, practical and complete. The subject of digitalis medication receives comprehensive and valuable treatment. Frequent historical references, and brief quotations from original writings add to the value of this work. Excellent descriptions of methods of hydrotherapy, physiotherapy, and dietetic advice are given simply and succinctly. Aside from its lack of information about sulphanilamide, and anti-pneumococcus serum, obviously due to their more recent development, the book makes an excellent addition to any physician's library.

Thomas Myers, M.D.

EMOTIONAL ADJUSTMENT IN MARRIAGE. Le Mon Clark. 261 pages. $3.00. St. Louis: Mosby, 1937.

Some thirty years ago a Minnesota physician went to prison because he sent through the mails a book which undertook to teach the art of sexual intercourse so as to elicit from it the highest enjoyment. The then President, Theodore Roosevelt, was appealed to for a pardon, but refused after reading a few extracts from the book. Such has been the change in attitude towards sex literature that Dr. Clark need fear no indictment, although his work is much more erotic than was that by the Minnesota doctor.

This is as it should be, provided the circulation of this kind of literature is kept strictly in the hands of the medical profession, by them to be entrusted to engaged or newly married couples. No one can practice medicine for any length of time without encountering numerous marital misfits because of faulty sexual relations, a condition that can be met only by the fullest and frankest discussion. A spade must be called a spade, and in order to be understood it may be necessary sometimes to lay aside purely scientific terms and resort to some of those current on the street; there must be no uncertainty in the minds of those to be instructed as to what is meant.

Dr. Clark bases his thesis on the claim that there can be no perfect union without bringing together both the physical and the psychical elements of love, consummated by sexual intercourse that satisfies both the participants. He describes the gradual approach by which this objective may be attained. Repeatedly he asserts that anything which is pleasurable to both is desirable. How to get this pleasure is minutely described, as also how to avoid the pitfalls into which many stumble. This calls for highly sensuous descriptions and he gives them, but his object is laudable and for the end in view he does not go beyond the limits of decency, although as intimated before, it would be most objectionable to put the work into the hands of those who would read it only from prurient motives.

Do doctors need the kind of information and instruction given in these pages in order to give the best and most intelligent advice to those who consult them on sexual matters? Yes, many of them do, and there are few who will not get some valuable points. The subject is seldom dealt with so intelligently and understandingly.

A chapter on birth control adds nothing new.

Some very erotic though classical poetry does not really belong in a serious medical book.

W. Davis

THE COMPLEAT PEDIATRICIAN. PRACTICAL, DIAGNOSTIC, THERAPEUTIC AND PREVENTIVE PEDIATRICS. Second, completely rewritten, edition. By W. C. Davison, Professor of Pediatrics, Duke University School of Medicine, formerly acting pediatrician in charge, The Johns Hopkins Hospital. Duke University Press, 1938, pp. 250.

For more than eight years on trains, steamers and planes from Helsinfors to Houston, the author of The Compleat Pediatrician read, rummaged and ransacked 147,359 cases of 329 different diseases among 80,000 children admitted to the Johns Hopkins Hospital from 1912 to 1932. The result is a book, not a textbook but an almanac, whose compressed 250 pages contain a vast collection of facts.

In this one volume encyclopedia, you will find: (1) one hundred and sixty-four signs and symptoms peculiar to childhood; (2) a concise summary of the differential diagnosis of 329 diseases of children; (3) the grain separated from the chaff in pediatric treatment (drugs and prescriptions especially valuable); (4) 213 practical laboratory tests that have stood the test of time; (5) the best facts in the growth, development, and guidance of children, which every nonmedical health worker as well as physician should know; and (6) excellent instruction for taking histories and making physical examinations.

If you want leisurely reading, do not buy this book, but if you want accurate, precise, practical, up-to-date pediatrics be sure to get a copy and make a constant companion of it.

One final word, the author urges that the reader follow the instructions on page 5 explicitly in order to understand the arrangement and the cross index.

M. Seham.

NEW PATHWAYS FOR CHILDREN WITH CEREBRAL PALSY. Gladys Gage Rogers and Leah C. Thomas. New York: Macmillan, 1935, 167 pp., illus., $2.50.

This is a practical, concise, readable discussion of the authors' experiences and observations in the education and development of the handicapped children at their summer camp, Robin Hood's Barn.

It is a book that the parents of a child with cerebral palsy should read, as it affords them a sane approach to their problems of education and the adjustment necessary in their lives to assure the maximum development of these children.

To the physicians it may serve as a manual in outlining toys, suggesting games and developmental exercises, both direct and indirect. It offers suggestions for construction of simple supportive apparatus. The physician can well afford to read further and develop the general approach to the education of these children that the authors have learned to be a fundamental part of their success.

HAROLD F. FLANAGAN, M.D.

WABASHA COUNTY SOCIETY

(Continued from Page 589)

Wabasha County Medical Society and the Wabasha County Dental Society at Lake City, Tuesday evening, July 8. About twenty-five were in attendance.

These officials explained the newly inaugurated system of having divisional health districts in the state. There are three such districts now, and the intention is to establish a fourth in Southeastern Minnesota, including Winona, Olmsted, Goodhue, Fillmore, Mower, Houston, Dodge, Dakota and Wabasha Counties, provided these counties qualify by employing a County Public Health Nurse and otherwise fulfilling the requirements of the State and Federal laws and regulations in this respect. It was unanimously voted by the organizations present to favor, advocate, and promote this measure.

CLASSIFIED ADVERTISING

FOR SALE—South Central Minnesota, good established practice. Home optional. Terms. Good place for young man. Address A-33, care MINNESOTA MEDICINE.

GOOD OPENING FOR PHYSICIAN at Bisbee, North Dakota. Deceased physician's residence, with modern equipment and instruments, for rent at $35.00 per month. Write Bisbee Commercial Club, attention P. O. Bugge.

GOOD PRACTICE in Minnesota village. Physician retiring wants successor. Address A-36, care MINNESOTA MEDICINE.

PHYSICIAN, graduate of Minnesota with many years' experience, who is being held from his work in China by conditions there, desires one or more locum tenens covering a period of three to six months. Address B. W. Jarvis, M.D., 2097 Iglehart Avenue, Saint Paul, Minnesota.

LABORATORY TECHNICIAN desires work in Twin Cities. Address A-35, care MINNESOTA MEDICINE.

LOCUM TENENS wanted during August. Can furnish car. Recent Minnesota graduate. General Hospital internship. Address A-38, care MINNESOTA MEDICINE.

FOR SALE—Portable nitrous-oxide, oxygen-ether apparatus for anesthesia. Good for rural obstetrics. Just returned from factory completely overhauled. Address A-37, care MINNESOTA MEDICINE.

WANTED—Position as secretary and technical assistant in doctor's office by young woman with some experience, excellent health, and good educational and social background. Opportunity for growth and experience more important than initial salary. References upon request. Address Edna Ring, Shakopee, Minnesota.

POSITION WANTED—As assistant in doctor's or dentist's office. Experienced. References. Address Mabel H. Combs, 4820 15th Avenue South, Minneapolis, Minn.

PHASES OF BRONCHOSCOPY AND ESOPHAGOSCOPY OF IMPORTANCE IN GENERAL PRACTICE

VIRGIL J. SCHWARTZ, M.D.
Minneapolis, Minnesota

THE DAY has long since passed when the practice of bronchial and esophageal endoscopy consisted only of the removal of foreign bodies from the air and food passages. It has become one of the most important procedures now in use for the examination and treatment of certain chest conditions. True, a major portion of the field is still devoted to the foreign-body problem; but more and more it has been enlarged to include the study and treatment of such conditions as primary carcinoma of the bronchi, malignancy (sarcoma or carcinoma) of the esophagus, lung abscess, tuberculosis, diphtheria, bronchiectasis, and tracheal stenosis or displacement due to thyroid enlargement, mediastinal gland involvement, or aortic aneurysm. Also to be considered are cicatricial stenosis, scleroma, asthma, unexplained vomiting of blood or regurgitation of food, and atelectasis due to thick lung secretions. Any unexplained interference with the function of swallowing, or of the stomach, and unexplained cough, dyspnea, hemoptysis, and expectoration call for appropriate investigation. Furthermore, marked advances in gastroscopy are also being made.

The mechanical problems associated with foreign-body extraction are naturally interesting. A few foreign-body cases which present particular points of interest will be discussed briefly. The esophageal foreign bodies encountered in this series include coins of various kinds (pennies, quarters, nickels, coin slugs), food in large masses, meat bones, pheasant bones, chicken bones, fishbones, open safety pins, straight pins, advertising buttons, wire rings, a thermometer, tin whistles, a peach stone, buttons, a dental bridge, and so on. Bronchial foreign bodies include nuts of various kinds, diphtheritic casts, a thumbtack, an acorn, a steel screw, fine pieces of carrot, a metal clasp from a dress, a broken portion of an intubation-tube obturator, beads, and others.

Until recently, one of the most tragic situations in the entire field of medicine was our comparative helplessness in the treatment of primary carcinoma of the lung. From a diagnostic standpoint, great advances had been made: a piece of tissue obtained through the bronchoscope settled the diagnosis immediately. Sometimes the patient may have been in splendid condition so far as general operative risk was concerned, and the process may still have been at an early stage of development; yet the danger of operation was so marked that it was generally not advised. In fact, even now a patient who is still in what he considers comparatively good health will not readily entertain the idea of submitting to an operation which has had such a high mortality rate. We have had, therefore, to resort to radium and deep roentgen-ray therapy. The latter had, in fact, given much encouragement. Yet, in general, this treatment is only a palliative measure, as most patients thus treated live considerably less than a year after the diagnosis is made.

Within the past few years, however, marked advances have been made in the surgery of carcinoma of the lungs. Reports of successful lobectomy and pneumonectomy are beginning to appear in the literature, and, if substantial progress continues, it is to be hoped that before long a

reasonably safe procedure will be developed for use in all cases which are not too far advanced.

Mrs. A. P., aged sixty-four, was a typical case. She had complained of shortness of breath for four or five years. A year previously she began to have a dry cough, with a little clear sputum. She noted some blood in the sputum, and expectorated small quantities resembling "cherry-pits" —small, round and sticky. There was no pain, but there was mild dyspnea. The appetite was good; there was no fever nor loss of weight. Anteriorly, on the left side the breath sounds were heard faintly, but the percussion note was almost normal. This is usually the case. Roentgenograms revealed some fluid which was removed. Bronchoscopy and biopsy showed a carcinoma. The patient left the hospital and it was reported that six months later she died.

Mr. W. J., aged sixty-four, was bronchoscoped and a similar condition was found except that instead of presenting a small tumor which only partly filled the bronchial lumen, as in the preceding case, the mass here was so large as to occlude completely the left bronchus.

Carcinoma of the esophagus is an even more discouraging and challenging disease. A common offense in this case is erroneous diagnosis through inferring that the patient's trouble is one of several benign or "nervous" conditions, such as esophageal spasm, cardiospasm, neurasthenia, hysteria, globus hystericus, refusal to swallow, et cetera, instead of doing an early esophagoscopy and giving the patient the benefit of such relief as radium and deep-ray therapy may offer. A still worse offense is the practice of blind bouginage. It is often the immediate cause of death in the presence of an ulcerated, weakened esophageal wall, and is greatly to be condemned, except possibly after esophagoscopy, when the operator is thoroughly familiar with the shape and condition of the particular esophagus in question. Even so, it is a dangerous procedure.

A striking case was Mrs. G. M., who had had increasing difficulty in swallowing for about seven weeks until at the time she was examined she was unable to swallow even liquids. This patient was only twenty-three years old; yet by means of the esophagoscope a carcinoma was found involving the entire circumference of the wall of the upper esophagus and causing almost complete obstruction.

Cancer is found most frequently in the middle third of the esophagus, somewhat less often at its lower end and least of all in the upper third. Jackson states that strangely enough the most frequent site in women is at the upper end as was the case in the patient just mentioned.

M. K., aged sixty-five, had been unable to swallow solids for weeks and fluids for many days. She was so weak and emaciated that she could not even sit up, yet esophagoscopy was not suggested to her until she came to the clinic. She, too, had a complete ring carcinoma of the upper end of the esophagus.

Another patient, Mrs. C. S., aged thirty-three, had complained of moderate dysphagia for a few weeks. By means of the esophagoscope there was found, in the right pyriform sinus, and extending downward from this for a short distance into the mouth of the esophagus, a sarcoma which was extensively and carefully treated by operation, radium and deep-ray therapy. The patient lived for about eighteen months. All except three of the men and two other women in this series of esophageal cancer showed lesions in the middle or lower third.

In conditions in which tracheal compression, due to goiter, mediastinal glands, tumors, aneurism or other lesions is suspected or evident, tracheoscopy is urgently and sometimes immediately indicated. Unfortunately, this is often delayed until it is too late. The writer received an emergency call to do a tracheotomy upon a patient who was in the operating room, and who was about to have a goiter removed, but became cyanotic on the table. She was found to have a scabbard trachea, which was so markedly compressed on each side by two enormously enlarged thyroid lobes, that it was difficult to understand why she had not suffocated long before. Tracheotomy was done and the patient recovered, but there were some trying moments. Tracheoscopy is easily and quickly done and frequently gives so much information that it should be resorted to much more often. It is frequently possible to tell by the pushed-in appearance of the tracheal wall just which of the two thyroid lobes is enlarged, and to exactly what degree it is encroaching upon the tracheal lumen. It is a well known fact that a patient may go for a long time with slowly increasing tracheal compression and not show any symptoms until sudden dyspnea and cyanosis set in.

Unexplained vomiting of blood in the pres-

ence of a normal stomach, normal chest findings and a normal nose and throat may be due to a simple esophageal erosion or benign ulceration. Mrs. M. S., aged fifty, had vomited about 1,200 c.c. of bright blood two weeks previous to her admission. It was impossible to find the source of this bleeding, so esophagoscopy was done and an ulcer was found on the posterior wall of the esophagus, thirty-one centimeters from the teeth, possibly due to food or bone trauma. This was cauterized and she has had no bleeding since that time. This type of bleeding is occasionally due to a small dilated vessel, usually a small varicosity, but while these are common in the hypopharynx and on the posterior surface of the root of the tongue, they are comparatively infrequent in the esophagus itself.

Grim as is the aspect in the matter of malignancy, it is exceedingly bright in the foreign body field. In this connection there are some points which warrant mention. First of all, it cannot be too strongly emphasized that the blind insertion of a finger, whether by a doctor or a layman, into the throat for the purpose of pushing down a foreign body is often a disastrous procedure. It is very rare that the finger can actually hook itself around a foreign body, and if the attendant states that he can "feel" it with the finger tip, it is possible that he himself may have pushed it down into an incarcerated position. The old saw that nothing smaller than an elbow should be put into an ear by one not qualified, applies almost equally well to the throat. The only thing that should be used for the re-

moval of a foreign body in the throat is a pair of forceps, of one kind or another, and under inspection.

The writer was called to see Mrs. C. S., who complained of sudden dyspnea and severe pain in the throat, evidently due to a bone which had just become lodged. The patient was carefully examined with the mirror and no bone was seen, so an x-ray plate was taken and that seemed to show nothing wrong within the photographed field. The only finding of any importance was a small, flat swelling, seen with the laryngeal mirror in the posterior wall of the hypopharnyx which could easily have been due to trauma. However, the patient was observed closely and told to report immediately if she felt anything sharp in her throat. On the fourth day she phoned and reported such a sensation, and upon looking into the lower part of the pharynx there was found a bone protruding from the swelling which had previously been noticed on the posterior wall. She then stated that when she first had a choking sensation, her excited son-in-law put his finger in her throat and feeling something there pushed it down hard. In this case he evidently pushed it through the mucous membrane of the posterior wall, but he could just as easily have pushed it into the anterior or lateral wall, in which case the result might have been fatal.

A. R., a year and a half old infant, had a coin slug in his throat which was forced down by a parent so that it was firmly embedded in the upper end of the esophagus. It was removed by esophagoscopy, but this procedure should not have been necessary because it could undoubtedly have been removed with a pair of simple forceps from the pharynx. In another instance a doctor pushed a piece of bone, loose in his own hypopharynx, down into his esophagus, inflicting severe trauma.

Grasping a child by the feet and holding him upside down while trying to have him cough out a foreign body may also be a fatal mistake. This happened in the case of M. N., a child of three. He was brought into the hospital after having stopped breathing about seven or eight minutes before. Tracheotomy was done immediately and an acorn was found firmly wedged in the subglottic space and between the vocal cords. It was impossible to restore breathing. The child had told his parents that he had inhaled an acorn. This had doubtless lodged in the upper part of one of the main bronchi, and had left him only one lung for breathing, but the parents immediately turned him upside down and forced him to cough, whereupon the acorn fell into the trachea and lodged in the subglottic space, causing spasm of the glottis, a completely blocked trachea, and suffocation.

In view of the common practice of leaving thermometers in the mouths of patients, it is surprising that these do not more frequently enter the esophagus or bronchi. The writer had the unique experience of removing intact a thermometer from the esophagus of M. A., a man with bulbar paralysis. This case was recently reported elsewhere as being the first, or among the first, of its kind on record.

An unusual case was that of H. T., aged seventy-one, who swallowed some food which became stuck in his esophagus. Upon entering the esophagus we found in about its middle third the major part of an entire peach, including the stone. This was removed by the exercise of considerably more pull than is usually applied, yet the patient apparently suffered no ill effect from his experience.

Some foreign bodies are not actually so large, but when the esophagus contains, for instance, a lye-burn stricture, certain foreign bodies are caught which might otherwise pass through. This was the case with G. G., aged 9. He swallowed some lye when a year and a half old and the resulting stricture had been repeatedly dilated since. On January 1, 1932, he swallowed a prune stone which stuck in the esophagus, but was removed without difficulty. In the absence of the stricture the stone would have gone through easily.

A distressing condition with which bronchoscopists have to deal is laryngeal and tracheal diphtheria. It is astonishing to see how frequently children, and occasionally adults, are allowed to go without antitoxin, either through neglect or through failure to make a diagnosis. The patient may be brought into the hospital moribund or so dyspneic and cyanotic that life is a matter of only a few minutes. In such cases immediate laryngoscopy and tracheoscopy, with removal of the obstructing membrane by suction or forceps, will very frequently accomplish what any other method will not. In some cases intubation is indicated, while in others even tracheotomy may fail because often the membrane or diphtheritic

cast extends downward into the main bronchi. G. K., aged 17, was brought into the hospital fighting so hard for breath that a fatal issue seemed unavoidable. This patient had been sick for about twelve days with gradually increasing dyspnea, yet no medical attention was sought. Through a tracheoscope a long diphtheritic cast was removed by suction. The patient's breathing immediately became easier and she eventually recovered. There was, of course, a great amount of edema of the laryngeal and tracheal mucosa, but this gradually subsided. This procedure is a well established practice in contagious hospitals, and deservedly so.

It must be borne in mind that many things may happen between the time that the x-ray plate is taken in any case of suspected foreign body, and the time of bronchoscopy. A. N., aged four, was brought into the hospital and the x-ray showed a thumb tack in the right main bronchus.

Within a half hour the thumb tack was found on bronchoscopy in the left main bronchus instead of the right. In other words, while lying on his left side, he had coughed the tack up into the trachea and promptly aspirated it into the left main bronchus.

Similarly J. L., aged eleven months, had definite x-ray evidence of a small dress clasp, such as is used in women's dresses, in his right main bronchus. At bronchoscopy within fifteen minutes nothing was found in the bronchial tree and a second x-ray showed it lodged in his stomach, it having been coughed up and swallowed.

A more interesting case is that of R. G., aged four. X-ray showed definitely a long bead in the right main bronchus. Within a few minutes she was on the operating table and while the instruments were being prepared she suddenly became cyanotic. We suspected the probable cause of her trouble and changed her position a little, with the result that her color improved at once. Within two or three minutes, however, her color again became bad, but by this time the bronchoscope was ready for introduction and the bead was removed from the trachea. It had been coughed from the right main bronchus up into the trachea, and so long as the lumen of the bead was in the long axis of the trachea she was able to breathe through the hole, but when the bead tilted to one side or the other, the air was shut off and the patient became cyanotic.

An unusual accident occurred during the insertion of an intubation tube in a case of laryngeal diphtheria. F. M., aged four, was deeply cyanotic, and upon attempting intubation the attendant was unpleasantly surprised to find that he was not able to insert the tube and that the distal portion of the metal obturator was missing. An x-ray plate was immediately taken and showed this piece to have been broken off and lodged in the bronchus to the left upper lobe. The foreign body was removed and the intubation then proceeded without trouble.

M. B., an infant of twenty months, was admitted with a clinical diagnosis of peanut in the right lung. The child experienced a severe bronchitis, as was to have been expected, but made a good recovery. The bronchial walls normally dilate during inspiration and collapse during expiration; therefore a piece of nut which lies in the lumen often will admit air during inspiration into the area distal to it, but in expiration the walls collapse and the air is imprisoned, causing emphysema. If the foreign body fills the bronchus completely during both inspiration and expiration, atelectasis results. In passing, it is well to repeat again that children under the age of three or four should not be given nuts to eat, but this injunction is rarely heeded.

A man, aged sixty-two, evidently of low mentality, was found to have an entire esophagus full of food. A great piece of meat and cartilage, measuring approximately 4 to 5 inches in length, 1.5 inches in width and 0.5 inch in thickness was removed. A great degree of traction, perhaps the equivalent of 3 or 4 pounds, was required. Upon removal the mass was found to have been literally strangled at the lower esophageal constriction; a deep groove encircled the mass at its middle, as though a heavy rope had been tied about it. This experience may throw considerable light upon the degree of spasm which the cardiac end of the esophagus may develop, for these constrictions must occur at times in people who do not have a foreign body at this point. From a general diagnostic and therapeutic angle, therefore, this case is important. Some careful work has been done by various investigators on the actual, measured degree of contraction or constriction possible at the lower end of the esophagus. This is often due to diaphragmatic compression.

Another case of peanut in the bronchus is mentioned only to emphasize the great necessity of correlating a very careful history with seemingly insignificant symptoms and physical signs. This six year old child had had a very slight coughing spell four days previously, while eating an ordinary candy bar. When first seen by a doctor she had a slight occasional cough with a few râles. There were no other complaints. Roentgenogram showed an almost normal chest on inspiration, but a slight emphysema of the right middle and lower lobes on expiration. A peanut was found not quite filling the lumen of the right bronchus, below the opening of the bronchus to the upper lobe.

A man, aged fifty-nine, had complained of difficult swallowing for some time, but there were no clinical or roentgenologic findings of any kind. Despite this, we found, on esophagoscopy, a ring of pathologic tissue at the cardiac end which, on biopsy, showed adenocarcinoma. This case again emphasizes the need for endoscopic

examination when an adequate explanation of persistent symptoms is not possible.

Cases of straight pins and safety pins in the esophagi of infants have been seen rather frequently. An uncommon foreign body, however, was a piece of egg-shell in the trachea which was producing symptoms through irritation and spasm out of all proportion to the size of the foreign body. These symptoms disappeared following removal of the egg-shell. Several cases of watermelon seed in the bronchi have been seen, all in young children three to five years of age.

A boy, aged eight, developed atelectasis and emphysema (in different lobes) following an abdominal operation. Bronchiectasis developed after a time and became very troublesome, but it was interesting to note that an injection of lipiodol yielded so much improvement that the boy was able to go about his customary duties, including attendance at school and work following school hours without any appreciable discomfort. Frequently bronchiectasis can be prevented by repeated aspiration of residual pus in the lungs or bronchial tree, the result of an acute suppurative inflammation in this area.

We do not usually expect to find more than one major foreign body in the same patient. Recently a child was brought in with a foreign body in the esophagus which was of the exact size of a five-cent piece. However, we noted that there was hardly enough shadow cast by this foreign body on the roentgenogram to enable us to call it a coin. At esophagoscopy we found a round, very sharp piece of tin which had been swallowed one month before, and had, in the meantime, produced a great deal of trauma in the esophageal wall. The interesting fact in this case is that the child had at the same time also swallowed an open safety pin which the local doctor was able to remove from the pharynx without much trouble. He did not suspect the presence of more than one foreign body. The case, therefore, indicates the advisability of an x-ray in all cases of foreign body in the air or food passages.

The foregoing reports are only a few which illustrate some general principles. Space does not permit a consideration of the entire series. However, on the basis of some of the experiences cited, a few important rules may be listed, as follows:

1. Never diagnose "nervous" (so-called) conditions in the esophagus without endoscopic examination, if symptoms persist.
2. Never practice "blind bouginage."
3. Never allow the age of your patient to influence your diagnosis unduly.
4. Never "push down" blindly a foreign body in the throat.
5. Never turn a child upside down to cough out a foreign body.
6. Never leave thermometers in the mouths of unattended children or mental incompetents.

On the other side:

1. Always examine early the bronchi or esophagus if malignancy or foreign body is suspected. The earlier this is done the better.
2. Always repeat roentgenologic examination if a known foreign body cannot be found.
3. Always be prepared for tracheotomy.
4. Always be on guard for non-opaque foreign bodies in the chest.

Bronchoscopy and esophagoscopy are in themselves safe, quickly-performed procedures. Do not fear them. If doctors and the laity can be impressed with the necessity of caution and precaution, as above outlined, it will mean the saving of lives which are even yet unnecessarily sacrificed.

Did you know that twenty-five million cows are milked daily in the United States and that the output of dairy products is estimated at three and one-third billion dollars annually? That Wisconsin headed the list in 1937 for cash farm income from the sale of milk with $168,255,000 and Minnesota fourth with $95,330,000? That Minnesota headed the list for butter production in 1936 with 289,830,000 pounds? That Wisconsin produced in 1936 over half of the 642,551,000 pounds of cheese manufactured in the country, while Minnesota rated far down the list with only 12,643,000 pounds production? That in 1908, Chicago enacted the first compulsory pasteurization law? That New York followed in 1912 and that since that date no milk-borne epidemics have been recorded in that city and it is estimated that yearly several thousand babies are saved there annually from cholera infantum?—From *Milk Facts,* Milk Industry Foundation, July, 1938.

THE USE OF PEDICLE MUSCLE GRAFTS IN FACILITATING OBLITERATION OF LARGE, CHRONIC, NONTUBERCULOUS, PLEURAL EMPYEMA CAVITIES*

HOWARD K. GRAY, M.D.
Rochester, Minnesota

THE obvious problem in the treatment of chronic nontuberculous pleural empyema is to obliterate the cavity or cavities as rapidly as possible with the minimum risk and deformity, and to restore to as nearly normal as possible the physiologic activities of the chest. With adequate treatment during the acute or subacute stage, most chronic empyemas can be avoided. Unfortunately, however, many cases are encountered in which inadequate drainage has been instituted and in which a chronic process therefore persists.

As is true of many pathologic conditions of the chest, time is an important factor, for the lesion may have produced widespread general effects and it is a constant source of potential danger. Not the least of such a patient's worries may be financial, and for this as well as for physical reasons, it is important that the period of rehabilitation be terminated as rapidly as possible.

Before resorting to any of the more extensive operative procedures, adequate drainage with appropriate local treatment of the chronic empyema cavity should be instituted. By so doing, the general condition of the patient will be improved, and the cavity may diminish appreciably in size or become completely obliterated. If the cavity is not too large, the "roof" may be removed subsequently in multiple stage operations. That further surgical treatment will be necessary and that extensive "unroofing" is inadvisable in an appreciable number of cases is readily admitted, and it is with special reference to the use of pedicle muscle grafts in facilitating obliteration of such cavities that this paper is primarily concerned.

With the exception of Lilienthal's "major noncollapsing thoracoplasty," most of the procedures advocated for the obliteration of large empyema cavities from within have been characterized by extensive deformity. The chief advantage of a modified decortication operation, such as was originally described by Fowler and Delorme, is the reinflation of the lung which occurs to a limited extent and in so doing may partially obliterate the cavity and restore a greater degree of vital capacity. Unfortunately, however, the procedure is applicable only in a very limited number of cases because of the frequent association of marked fibrosis in the underlying pulmonary tissue and it cannot be carried out without appreciable risk.

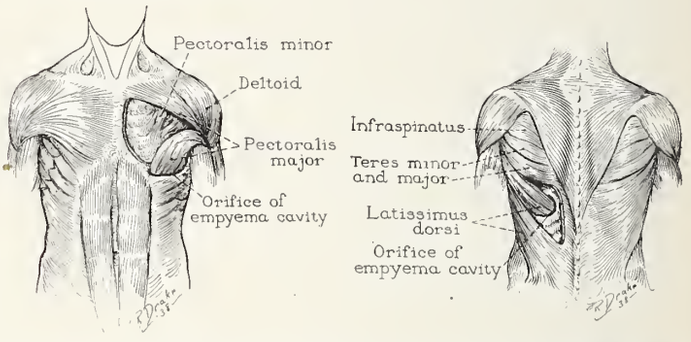

Fig. 1. Showing the accessibility of *a*, the pectoralis major muscle, and *b*, the latissimus dorsi muscle for pedicle muscle grafts in facilitating obliteration of large, chronic nontuberculous pleural empyema cavities.

Similar criticism of the marked deformity and unwarranted risk imposed may be directed at most procedures designed to obliterate the empyema cavity by collapsing the thoracic wall. This can be accomplished only after the bony framework has been removed, whether it be by the radical thoracoplasty of Schede or the many modifications of this procedure in which the soft tissue is preserved.

If obliteration of a large empyema cavity by permitting the lung to expand is impracticable and if by collapsing the wall of the chest too great a risk and deformity are imposed, the only method by which obliteration may be accomplished is to assist the natural healing processes by filling the cavity with some foreign substance. In order to conform to accepted surgical principles, it is essential that this substance be viable. Because of their accessibility, the pectoralis major and the latissimus dorsi muscles are ideally suited for the purpose (Fig. 1).

*From the Division of Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the meeting of the Minnesota Surgical Society, Minneapolis, Minnesota, May 20, 1938.

According to Gray, the latissimus dorsi muscle "arises by tendinous fibers from the spinous processes of the lower six thoracic vertebræ and from the posterior layer of the lumbodorsal fascia (by which it is attached to the spines of the lumbar and sacral vertebræ, to the supraspinal ligament, and to the posterior part of the crest of the ilium)." It is inserted into the bottom of the intertubercular groove of the humerus and receives its blood supply through the subscapular artery, a branch of the axillary artery. Impulses pass to the latissimus dorsi muscle along the sixth, seventh, and eighth cervical nerves through the thoracodorsal (long subscapular) nerve. The pectoralis major muscle arises "from the anterior surface of the sternal half of the clavicle, from half the breadth of the anterior surface of the sternum as low as the attachment of the cartilage of the sixth or seventh rib, from the cartilages of all the true ribs, with the exception, frequently, of the first or seventh or both, and from the aponeurosis of the obliquus externus abdominis." The muscle ends in a flat tendon, which is inserted into the crest of the greater tubercle of the humerus and receives its blood supply chiefly through the thoraco-acromial and lateral thoracic arteries, both of which are branches of the axillary, and through the perforating branches of the intercostal and internal mammary arteries. Impulses pass to the pectoralis major muscle along the medial and lateral thoracic nerves. Through these nerves the muscle is to receive filaments from all the spinal nerves entering into the formation of the brachial plexus.

The origin and insertion of these two muscles make them particularly suitable for pedicle muscle grafts. The base of the pedicle in both instances is preferably the insertion of the muscle, for in preserving the tissues in this region there will be no interference with the nerve and blood supply. Although the origin may be changed by transplanting the bulk of these muscles into some intrathoracic cavity, the major portion of their function will be retained if there is no interference with the points of insertion.

Report of Cases

Case 1.—The first patient, a youth aged seventeen years, registered at the clinic on March 11, 1936. Five weeks previously a diffuse bronchopneumonia had developed on the right; this was complicated by a hemolytic streptococcic empyema. Multiple thoracentheses were performed between March 11 and April 7, and open drainage was instituted by removing a portion of three ribs in the region of the most dependent portion of the empyema cavity. The capacity of the cavity at this time was approximately 750 c.c. and it

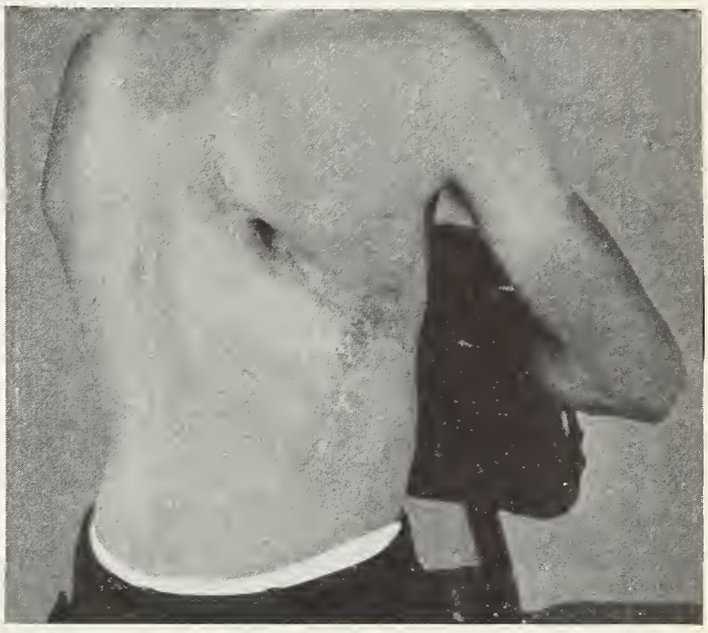

Fig. 2 (Case 1). Showing the line of incision which was made at right angles to the thoracotomy incision in order to mobilize as much as possible the intact portion of the latissimus dorsi muscle.

extended nearly to the apex of the right hemithorax, compressing the lung medially. The patient was dismissed from the hospital on the fourteenth postoperative day and for the next two weeks returned for daily irrigations and dressings. On May 6 (one month after the open operation) the skin flap on the outer portion of the thoracotomy wound was dissected back and a perpendicular incision was made from the outer third of the lower flap in the direction of the fibers of the latissimus dorsi muscle. A pedicle graft of the latissimus dorsi muscle, approximately 20 cm. in length, was dissected free, leaving the pedicle attached above. This was inserted into the empyema cavity and held in place with one suture. Plastic closure of the skin, where it was dissected free, was then made, along the line of the new incision. The capacity of the cavity at this time was approximately 500 c.c. The wound was packed lightly with vaseline gauze. The patient's convalescence was uneventful and he was dismissed from the hospital on the fourth postoperative day (Fig. 2). Final surgical dismissal was granted two weeks later, and the patient was permitted to return home. His local physician continued to irrigate the residual cavity and complete healing occurred within three months after his dismissal.

Case 2.—The second patient was another youth, also seventeen, who registered at the clinic on September 2, 1937. In April, 1934, a right pleural empyema had developed following pneumonia. Drainage of the empyema cavity had been instituted (elsewhere) a week later but the wound had continued to drain at intervals in spite of several operations for osteomyelitis

of the ribs. There had been considerable loss of weight and, since the operation, the patient had noticed definite curvature of the spine. On physical examination the patient appeared to be poorly developed and poorly nourished; he had a moderately sallow

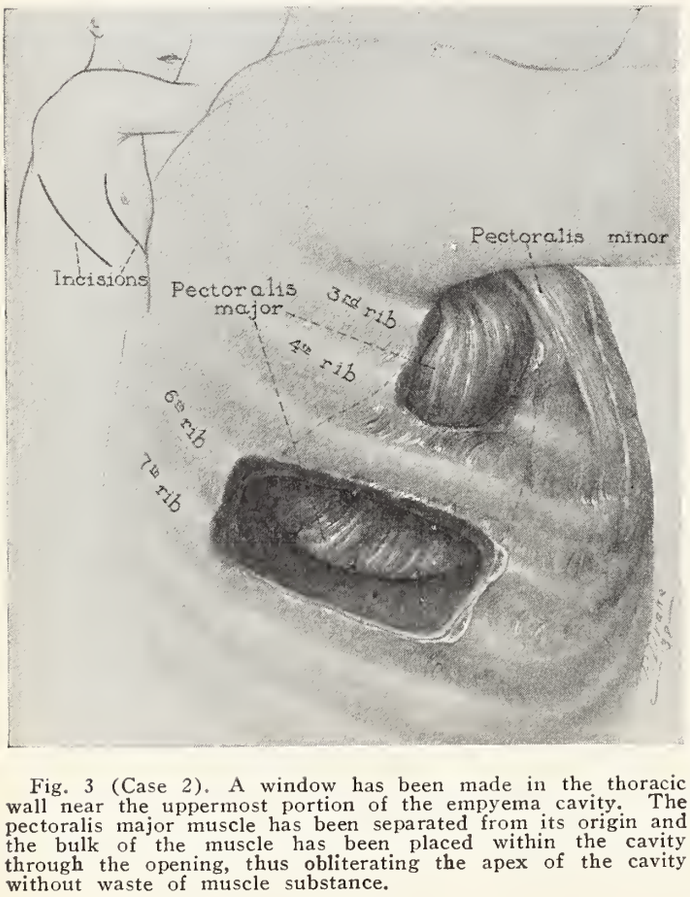

Fig. 3 (Case 2). A window has been made in the thoracic wall near the uppermost portion of the empyema cavity. The pectoralis major muscle has been separated from its origin and the bulk of the muscle has been placed within the cavity through the opening, thus obliterating the apex of the cavity without waste of muscle substance.

complexion. Dulness and diminished breath sounds were noted over this entire right side. A roentgenogram of the thorax revealed a large amount of fluid on the right and evidence that partial resection of the eighth, ninth, and tenth ribs had previously been carried out. Moderate scoliosis was seen in the roentgenograms of the thoracic and lumbar spine.

A needle was inserted in the seventh interspace in the posterior axillary line on the right and a large quantity of thick, yellowish-green pus was found. Staphylococcus aureus was cultured from this material.

On September 10 open operation was carried out. After removing a portion of the ninth rib posterolaterally, the empyema cavity was entered. It was found to extend practically from the diaphragm to the apex of the right hemithorax. The lung was compressed medially. The cavity held approximately 1,000 c.c. of thick, yellowish-green pus containing very large clots of fibrin. A portion of what appeared to be regenerated eighth and ninth ribs was removed and also a portion of the tenth rib, leaving an opening into the thoracic cavity approximately 20 cm. in its longest diameter and 12 cm. in width. The cavity was packed lightly with vaseline gauze. The patient was dismissed from the hospital on the thirteenth postoperative day and returned for daily irrigations and dressings.

On October 8 (one month after the open drainage), the patient reëntered the hospital for further surgical treatment. A large empyema cavity still persisted which extended medially and upward approximately 15 cm. from the anterior and superior border of the edge of the opening to the cavity. A long, slightly curved, linear incision was made along the fifth rib, and a skin flap over the pectoralis major muscle was reflected as far as the midsternal line. The pectoralis major muscle was then dissected from its points of origin and reflected upward and laterally. Portions of what appeared to be the fourth and fifth ribs anterolaterally were removed with the intervening muscle bundle, and by so doing a window was made in the uppermost part of the empyema cavity. Through this window and also through the lower opening, the visceral pleura was cross-hatched according to the method of Ransohoff. The pectoralis major muscle was then brought through this opening into the empyema cavity and held in place by several sutures to the thickened visceral pleura (Fig. 3). The incision over the pectoralis muscle was then closed tightly. Following this procedure the patient was dismissed from the hospital on the thirteenth postoperative day, final surgical dismissal being granted on November 12, slightly more than a month after the second operation. Following the patient's dismissal the wound was irrigated and dressed by his mother, as the patient lived in a sparsely settled part of one of the western states. In her last letter (dated May, 1938) she said that the cavity would hold only a 5-inch strip of gauze. Her son had attended school all winter and felt well.

Comment

These two cases illustrate circumstances in which the use of muscle pedicle grafts are of value in facilitating obliteration of large, chronic, nontuberculous empyema cavities. The procedure is not new, as it was advocated more than twenty years ago by Robinson. As is true of so many worth-while procedures, however, it has gradually fallen into disuse and in recent years has been mentioned only briefly by those interested in this field of surgery. It should not be looked on as a procedure intended to supplant others but rather as one to supplement the surgical armamentarium of those whose responsibility it is to rehabilitate these unfortunate persons as rapidly as possible, and with the minimum deformity and interference with normal function.

ACUTE UPPER RESPIRATORY INFECTIONS WITH GASTRO-INTESTINAL SYMPTOMS*

EDWARD DYER ANDERSON, M.D.
Minneapolis, Minnesota

THE purpose of this paper is to discuss from a strictly clinical standpoint, the gastro-intestinal symptoms which so frequently occur in children with respiratory infections, and in particular the condition which is commonly called "intestinal flu."

It has been known for many years that in children, gastro-intestinal symptoms may be the predominant complaint in various respiratory diseases. In general, the younger the child, the more marked the intestinal symptoms. A child or infant may have anorexia, abdominal pain, vomiting, diarrhea or a combination of these symptoms. They may be mild or severe. A child suffering from an upper respiratory infection ranging in severity from a simple head cold to a lobar pneumonia may show any or all of these gastro-intestinal symptoms.

Whereas in the past, it was assumed that a child showing marked intestinal symptoms had an infection directly involving the gastro-intestinal tract, today we realize that in the majority of instances there is no actual intestinal infection, but rather that the symptoms are brought about by the absorption of toxins from a parenteral infection.

In the most common type of respiratory infection, namely, the simple head cold, the intestinal symptoms vary greatly with the age of the child. In children over two years of age, anorexia is usually the chief and in most instances the only one found. The lack of appetite may be extreme and last for the duration of the cold. If the mother does not force or urge the child to eat more than it wants, the appetite returns when the cold is over and no harm is done. However, if feeding is forced, it may cause a more serious gastro-intestinal disturbance or as so frequently happens, the child may develop a chronic anorexia. I am convinced that many children with persistent poor appetites and poor feeding habits can trace the beginning of their trouble to a simple upper respiratory infection, at which time they were forced and urged to eat when they had no desire for food, by an over-solicitous mother. Their appetite was never allowed to return to normal because of continued forcing of food.

In babies and small children, anorexia is usually a marked symptom accompanying a simple head cold. This is probably due to both absorption of toxins and to the mechanical obstruction of breathing with resultant difficulty in taking food.

Besides anorexia, babies frequently have vomiting, diarrhea and abdominal pain. Allowing the child's appetite to determine the amount of food taken and removing laxative foods from the diet in cases of diarrhea, are usually the only measures needed other than those used for the treatment of the cold. As soon as the cold clears up, the gastro-intestinal symptoms disappear quickly.

In the more severe respiratory infections, such as tonsillitis, grippe, influenza, scarlet fever, measles and pneumonia, the intestinal symptoms are more frequent and severe in all ages of childhood. Abdominal pain is the most frequent symptom. This may vary in intensity from mild abdominal distress to extreme pain which may simulate the pain of appendicitis or even that of intestinal obstruction. The importance of never operating upon a child for appendicitis until one is convinced that the pain is not the result of an upper respiratory infection has been so well and frequently called to our attention by Brennemann and others that I do not feel it necessary to discuss it further in this paper.

I do, however, wish to speak of the opposite phase of this subject. Although much has been written about the danger of operating unnecessarily when the abdominal symptoms are the result of respiratory infections, comparatively little has been said about the great danger of overlooking a surgical abdomen due to a false sense of security when a respiratory infection is present in the patient. When there is evidence of respiratory infection it is very easy for us

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1938.

to become careless and miss an acute appendix or obstruction, because we assume the abdominal symptoms are due to the respiratory infection and we either do not examine the abdomen at all, or, if we do so, do it inadequately. In other words, we must constantly remember that just because a cold, sore throat or other respiratory infection is present, it does not rule out the possibility of a surgical condition also being present in the abdomen. This is particularly true when we realize that there is considerable evidence that acute appendicitis may occur as a direct complication of an upper respiratory infection. Also, the fact that intussusception occurs frequently when diarrhea is present should put us constantly on guard against careless diagnosis.

Although many children have been operated upon unnecessarily for abdominal conditions which did not exist, and in whom an upper respiratory infection was the cause of the symptoms which led to a mistaken diagnosis, nevertheless, I am convinced that many more have been allowed to die because either the parents or physician, or both, have been lulled into a feeling of false security because an upper respiratory infection was present, and have neglected to recognize that an acute abdominal condition also existed. Certainly, every child who has persistent abdominal pain should be examined thoroughly and carefully with the possibility of the presence of both an upper respiratory infection and a surgical condition of the abdomen always in mind.

During the last few years a gastro-intestinal condition has been prevalent at various times which is called by the laity and often by ourselves, "intestinal flu." I am sure we all have a peculiar feeling about this term. When a mother tells me that she thinks her child has intestinal flu I unconsciously squirm, and when I use the term myself I consciously squirm. Undoubtedly, this feeling of apology which most of us have when this term is used is due to the fact that we realize that the name is a misnomer, and also that we of the medical profession know so little about the true etiology, bacteriology and pathology of this condition. Perhaps one should hesitate to discuss a disease about which so little can be offered from a purely scientific standpoint. The fact that one meets it so frequently makes me feel that a clinical discussion is warranted. Although intestinal flu is the most commonly used term, many others have been given to this clinical picture, such as, "intestinal cold," "intestinal grippe," "gastro-enteritis," and finally the one which is perhaps the most accurate but certainly too cumbersome for practical purposes, namely, "an upper respiratory infection with gastro-intestinal symptoms."

In this paper I shall use the term "intestinal flu," simply because it is the one most commonly used, and not because I think it is a scientific or good one. Although we do not definitely know what organism is the cause of this symptom syndrome, what evidence we do have would indicate that it definitely is not caused by the influenza bacillus. The term would also imply that the infection is one of the gastro-intestinal tract itself. There is considerable doubt as to whether there is any actual infection of the intestinal tract but rather that the intestinal symptoms are brought about by absorption of toxins from the upper respiratory tract. Many clinicians and pathologists do not think that the condition is a separate entity in itself but rather that it is an ordinary upper respiratory infection. At the present time I do not think we can say positively that it is a separate entity caused by a specific organism, but nevertheless, the symptoms are so definite and often so severe, and the physical findings so uniform, that from a clinical standpoint it does seem an entity. Whatever the name and whatever the etiology, the fact remains that we are dealing with a disease that is common, troublesome to the patient and one which offers problems both in diagnosis and treatment to the physician. Personally, I feel that it probably is due to a virus closely related to that of the ordinary cold. Until the etiology is definitely determined, this symptom-complex will probably continue to be called "intestinal flu" by the laity and by the majority of physicians.

The symptoms of intestinal flu are varied and give us several types of the disease. The most common type is that in which vomiting is the outstanding feature. Although the onset of the vomiting may be preceded by symptoms of a head cold or a mild sore throat, nausea and vomiting are the first and predominant symptoms in the majority of cases. The onset is sudden and the vomiting severe and frequent. Retching continues long after the stomach is

empty. This retching will often continue for hours and in some instances for two or three days. The taking of any food or fluid usually aggravates the vomiting. Even small sips of water cause immediate emesis. The child becomes markedly exhausted and if the condition persists long enough may develop dehydration and, in severe cases, acidosis. In the majority of instances the children do not complain of sore throat, but they do have severe headache and often have abdominal cramps, which are particularly severe just before vomiting. Extreme restlessness is frequently present and sleep is fitful and broken. Anorexia is invariably present and is usually extreme. Temperature is generally present and may be high but in the majority of cases is low, varying from 100 to 101 (rectal). The white blood count is usually within normal limits or slightly elevated. Physical examination shows a child with a distressed facial expression and with marked pallor. However, if the vomiting has persisted long enough to cause dehydration the skin may appear flushed. The physical finding almost invariably present is the injection of the veins along and about the pillars of the throat. These dilated veins are also on the back of the pharynx but are particularly noticeable about the pillars. When vomiting persists for several hours one usually finds generalized soreness of the abdominal muscles.

In some cases the course of the disease is short and within a few hours the child feels well, wants to play and his appetite returns. In most instances, however, the nausea and vomiting last from twelve to forty-eight hours. After the nausea stops, anorexia and weakness persists for several days and occasionally the child remains languid, tired and has no appetite for several weeks.

Complications

Acidosis must be watched for and guarded against by the giving of adequate fluids which necessitates at times rectal or subcutaneous administration.

I believe that appendicitis may and does occur in some instances as a direct complication of intestinal flu. In three cases I have seen, I am convinced that acute appendicitis developed on the third or fourth day from the onset. Both because intestinal flu may simulate acute appendicitis and because appendicitis may develop as a complication, it is imperative that every child with abdominal pain and vomiting should be carefully watched.

Various forms of treatment are advocated in the vomiting type of intestinal flu. Personally, I have found the following the most satisfactory procedure. All food is withheld until the child acts hungry and demands food. Until there has been no vomiting for twenty-four hours the only food given is gelatin, jello, dry toast or soda crackers, dry puffed rice or wheat or unbuttered popcorn. The youngster is also allowed to suck pure stick candy.

When there has been no vomiting for twenty-four hours, broth, soft boiled or poached egg, and cooked cereal are added. If no vomiting occurs for another twenty-four hours, the child is allowed to have his regular diet if he desires. At no time is he urged to eat.

In small infants breast milk or milk mixtures diluted to half of the regular strength are given at the regular feeding intervals if the baby wants food.

When the child cannot retain plain water, the only liquids given by mouth are French Vichy water or ginger ale until there has been no vomiting for twenty-four hours. These are given cool and in small amounts. When there has been no vomiting for twelve hours, plain water is given if the child prefers. Milk is not given until vomiting has ceased for at least forty-eight hours. If there is considerable dehydration or any evidence of threatened acidosis, fluid is given rectally or subcutaneously.

The drug which has been found most useful in combating excessive vomiting is chloral hydrate given by rectum. If given long enough and in dosage sufficient to keep the child quiet and resting for twenty-four hours, in the majority of cases the chloral can be discontinued and the vomiting will not recur if the proper diet is given and no effort is made to force the child to eat. Chloral hydrate per rectum is also very effective in relieving the abdominal pain which is so often present.

There are a considerable number of children suffering from the vomiting type of intestinal flu who get over the acute nausea after two or three days, but who do not seem to completely recover. Their appetite does not come back, and they appear languid and tired. Many of them will have abdominal cramps from time to time.

This chronic condition may go on for weeks. In these children the giving of acidophilus bacilli in the form of acidophilus milk or as a straight culture will usually quickly restore them to their normal condition. The child is kept in bed until all acute symptoms have subsided. This chronic type so frequently develops as a sequel of the acute form, that I routinely give my patients some form of acidophilus bacilli for a week, starting as soon as the nausea has stopped.

A second type of intestinal flu is that in which diarrhea is the outstanding feature. The diarrhea may vary greatly in severity. The majority of children have frequent stools for from twelve to thirty-six hours, at the end of which time the stools return to normal in a comparatively short time. In some instances the diarrhea may be severe, last for several days and may lead to marked dehydration and even severe acidosis. The stools may vary in number from four to twenty in twenty-four hours. They are watery and have considerable mucus. Blood is rarely seen and, if present, is in the form of small flecks. The stools are usually light in color. They have a foul odor and tend to cause marked excoriation of the buttocks. Cramps are almost invariably present and are severe. Tenesmus is a frequent symptom. Anorexia in most instances is severe. Headache is more common than in the vomiting type. Weakness and restlessness develop in the severe cases. The outstanding physical finding is the same as in the vomiting type, namely, injection of the veins about the pillars of the throat and pharynx. Generalized abdominal soreness is usually present. Temperature may be absent or may be high, but in most instances is from 100 to 102 (rectal).

The treatment I have found most satisfactory is as follows: The child is kept in bed until all acute symptoms have subsided. If nausea is not present, fluids, with the exception of fruit juices, are given by mouth in large amounts. If unable to retain fluids by mouth or if an adequate amount cannot be given to guard against excessive dehydration and acidosis, subcutaneous fluid is given. Food is given if the patient is not nauseated and wishes to eat. Any simple food is given with the exception of those which are laxative. If chloral hydrate can be retained by rectum it is given to relieve the abdominal cramps. If it cannot be retained and no nausea is present, paregoric by mouth is usually effective. If neither of these can be retained, and the cramps are severe, codeine is given hypodermically. Because of a marked tendency for these children to develop a chronic condition of poor appetite and fatigue following the diarrheal type of intestinal flu, I routinely give them some form of acidophilus bacilli for at least one week. This seems to prevent the occurrence of a prolonged convalescence.

In a considerable percentage of cases of intestinal flu, the patient has both nausea and diarrhea. In these cases the prostration tends to be greater and the danger of acidosis is increased. Subcutaneous fluid often has to be given. The dietary regime is the same as outlined above and codeine by hypodermic may be used to control the restlessness, pain and excessive vomiting. Acidophilus bacilli given by mouth as soon as the nausea stops seems to hasten complete recovery.

Another type of intestinal flu is occasionally seen in which neither vomiting nor diarrhea are present, but in which abdominal cramps, which may be frequent and severe, are the only symptoms. The cramps may persist for many days. The throat findings are the same as previously described. There is usually temperature, and chloral hydrate per rectum is the most effective way of controlling the pain. Acidophilus bacilli given by mouth for several days is of value.

Summary

Attention is called to the frequency with which gastro-intestinal symptoms occur in children who have respiratory infections. The importance of examining all children having abdominal pain or vomiting, for both respiratory infections and surgical conditions of the abdomen, is emphasized. The symptomatology, physical findings and treatment of the condition called "intestinal flu" are discussed.

SOLITARY DIVERTICULITIS OF THE CECUM*

W. N. GRAVES, A.B., M.D., F.A.C.S.
Duluth, Minnesota

IT is not my intention to discuss diverticulitis of the colon in general but rather to confine my remarks to inflammatory conditions of solitary diverticuli of the cecum, an entity confused with and encountered in the operation for that most common surgical emergency, appendicitis. I have been able to find only twenty-three such cases in the accessible literature, to which I wish to add the accounts of two cases occurring at identical sites on the cecum in two members of one family, a father and daughter.

Case 1.—Mrs. R. L. C. was seen on December 29, 1936, complaining of pain in the right lower abdomen. This began two nights before as generalized abdominal pain and became localized the following morning. The pain was dull and intermittent and was aggravated by change of position, walking, etc. There was no nausea or vomiting. For two or more years there had been soreness in the right loin but there had never been any severe attacks. She did notice, however, that the pain was worse on fatigue. Constipation was never a prominent symptom but she had been troubled for some years with "gaseous indigestion." Otherwise her past and family history were irrelevant except that eight years prior to this I operated upon her father for suppurative diverticulitis of the cecum, which case will be included in this report.

Physical examination revealed an adult female aged forty-nine. Findings were limited to a marked tenderness at McBurney's point extending upwards along the crest of the ilium. Muscle spasm was present over this area. No mass could be definitely outlined though there was a suggestion of it above the iliac crest. Vaginal examination was negative except for tenderness high in the right fornix. The temperature was 100 degrees F. Blood examination revealed 20,000 leukocytes. The urine examination was negative.

The pre-operative diagnosis was acute gangrenous appendicitis. Under cyclopropane and ether anesthesia, a right rectus incision was made. Upon opening the peritoneum free fluid was encountered. The appendix was markedly injected and edematous. It was removed in the usual manner and the stump invaginated. On the lateral surface of the cecum, opposite the ileocecal valve, was a severely injected, hard mass about one-half the size of a golf ball, covered with adherent omentum. No dimple could be palpated in this mass and it was thought to be either a phlegmon, diverticulum, or tumor. The attached omentum was ligated and transected and the mass delivered into the wound. There was marked edema of the greater portion of the cecal wall and because primary excision would have necessitated removing almost all of the anterior and lateral walls, it was entirely extraperitonealized by suture of the visceral and parietal peritoneum. Vaseline gauze was applied and the wound left open. Six days later the mass was removed by means of the endotherm knife. In cutting through edematous serosa and muscularis, the mucosa appeared normal and uninvolved. Therefore, the dissection was carried just outside the mucosa until the center of the mass was reached, when it was found that the mucosa invaginated into the mass. At this time a definite diagnosis of diverticulitis was made. The mucosa was ligated and invaginated with a purse-string suture. The muscularis and serosa were sutured over the stump and the wound closed with drainage. Convalescence was normal except for mild infection of the wound and no fistula resulted.

The pathological report as given by Dr. G. L. Berdez was as follows: "This is a specimen measuring 5.4 by 5 by 3 cm. The external surface is quite congested and shows in places fibrino-purulent deposits. The surface shows also a somewhat irregular opening measuring up to .4 cm. in diameter leading into a diverticulum; the cavity of the diverticulum is almost spherical, measuring up to 1.2 cm. in diameter, and is filled with fecal material and fetid purulent exudate. The internal surface of the diverticulum is lined by mucosa; in the distal extremity the diverticulum shows a small perforation which leads into the surrounding adipose and scar tissue. A large mass of quite edematous and congested adipose tissue, which shows several scar-like areas, is connected with the external wall of the diverticulum and forms the main part of the specimen.

"Microscopically the internal surface of the diverticulum is lined by mucosa having the structure of the mucosa of the large intestine. The lumina of some of the glandular tubules are dilated and filled with polymorphonuclear leukocytes. At one place the mucosa is ulcerated; the defect is lined with a mass of fibrino-leukocytic exudate. The deeper layers of the wall of the diverticulum are formed mainly by a mass of moderately cellular, partly new formed, connective tissue. The muscularis mucosæ can still be recognized in those parts of the diverticulum which are still represented in places. At other places of the wall of the diverticulum, the muscular layers cannot be demonstrated.

"Diagnosis: Diverticulum of the cecum with chronic inflammatory changes and acute exacerbation."

Gross and microscopic examination was also made of the appendix, which showed marked, diffuse congestion. The proximal half of the lumen contained purulent mucous material and the mucosa was congested and edematous. The distal half was thickened and

*Read before the Duluth Surgical Society, November 18, 1937.

fibrous and obliterated by a mass of scar-like fibrous tissue. Dr. Berdez' diagnosis was "chronic appendicitis with acute exacerbation."

Since her recovery, Dr. J. R. McNutt, radiologist, examined the colon fluoroscopically and by radiograms and no other diverticuli or abnormality was found in the entire large bowel.

Case 2.—Mr. W. R. S. was seen August 30, 1929, because of pain in the right lower quadrant which had persisted for thirty-six hours. There was no nausea or vomiting. He had many complaints which were not referable to his abdomen but were due to degenerative changes accompanying old age.

Physical examination revealed a white male, aged 69, very obese, and apparently suffering considerable pain. Essential findings were in the right lower quadrant, where there was a marked tenderness and rigidity of all the muscles. There was a suggestion of a mass but it could not be definitely outlined due to the large amount of adipose tissue present. His temperature was 100.8 degrees F.; pulse 100; leukocytes numbered 19,200.

Under spinal anesthesia, with a pre-operative diagnosis of acute appendicitis, the abdomen was opened through a right rectus incision. A mass the size of a baseball was delivered which involved the cecum, appendix and omentum. In the center of this mass was an abscess surrounding an inflamed, perforated diverticulum on the lateral surface of the cecum. The appendix was removed but was intact. Drains were inserted to the site of the diverticulum and also extraperitoneally. Convalescence was marred by development of fecal fistula and other complications incident to his heart and other organs, but he evenutally recovered.

The postoperative diagnosis was intra-abdominal abscess due to suppurative diverticulitis. The pathologist reported only fibrous appendicitis.

Unfortunately, there was never a colon study made to prove that this was a solitary diverticulum but none were seen at the time of operation.

In summarizing the twenty-five reported cases, thirteen were in females averaging in age 44.1 years, the most common age incidence in this group being between 45 and 60. Twelve were males averaging 38.1 years in age. The condition occurred most commonly between the ages of twenty and thirty-five. The youngest was a female, aged 3, and the oldest a male, aged 69. The pre-operative diagnosis was acute appendicitis in all cases except one, which from previous barium study was diagnosed carcinoma of the cecum. In analyzing the symptoms of the reported cases, the chief complaint in all the patients was pain in the right lower abdomen of a few hours to a few days duration, accompanied by nausea and vomiting in 50 per cent of the cases. Two of these patients gave histories of almost continuous aching in this region and four had complained of flatulent dyspepsia for years. The findings common to appendicitis which were noted in this series were: fever varying from 99 to 102 degrees F. in 74 per cent of the cases; rigidity and tenderness, either together or singly, in all but three cases. The average leukocyte count taken in six cases was 18,381, a somewhat higher average than is usually seen in acute appendictis.

The operations done were as follows:

Primary diverticulectomy	9
Delayed diverticulectomy	1
Invagination	2
Ileocolectomy or cecectomy	12
Drainage of abscess	1

In the cases in which primary diverticulectomy was done, the condition was recognized as a diverticulum by palpation of a dimple within the bowel, or by noting a concretion, or the mass was assumed to be a small tumor or inflammatory area surrounding an ulcer. The delayed operation was explained in my case above.

In the two cases in which invagination was done, the diverticulum in one was pea sized; the other was three-fourths of an inch in diameter and after extruding a concretion there was little induration present, making invagination the most logical procedure.

The more radical operations of ileocolectomy or cecectomy were done because the condition was mistaken for carcinoma, tuberculosis, tumor or ulcer. The case in which drainage was done has already been explained.

Mortality: All patients recovered except that of Portier, in which it was thought pre-operatively that there was a carcinoma of the cecum present and a resection of the right colon was done, the patient dying from gangrene of the gut.

Comment: There is much conjecture about the cause of solitary diverticuli of the cecum. Greensfelder and Hiller theorize on the origin as follows: "We should like to suggest another possibility, though a congenital one, as a factor; namely, the retention in some residual form of the appendix, which appears early in embryological life but normally disappears before the true appendix develops." In a study covering 5,385 major operations and 400 adult autopsies, they were able to find four cases of small traumatic diverticuli occurring after purse-string suture during appendectomy.

One must allow the possibility that solitary diverticuli of the cecum may be congenital in origin rather than acquired, which is the generally accepted opinion. In twenty-three of these twenty-five cases found in the literature no diverticuli were evident in other parts of the colon. According to Bargen, diverticulosis of the colon occurs most commonly between the ages of fifty-five and fifty-nine and rarely under thirty. The average age of this series was 41.2 years with 36 per cent under thirty. He also states that the incidence ratio of diverticulitis of the colon of males to females is 2.75:1. This series shows slightly greater occurrence in the female. All muscle layers were found microscopically in nine of the fourteen above cases in which studies were done, and the appendix was present in all cases. To the reported cases may be added the two here reported with diverticuli occurring opposite the ileocecal valve in two members of the same family, a father and daughter.

Summary

1. Many solitary diverticuli of the cecum are probably congenital but acquired diverticuli may follow ulcerative processes or surgical trauma.

2. They occur in a much younger age group than does diverticulosis of the colon in general.

3. Solitary diverticulitis of the cecum presents practically the same symptoms and findings as acute appendicitis.

4. The condition should be sought for and when found, invagination or primary diverticulectomy performed if possible.

5. In the presence of marked induration of the cecum delayed extraperitoneal diverticulectomy is a safe and desirable procedure.

6. Suppurative diverticulitis of the cecum may be mistaken for appendiceal abscess.

7. The fact that Bennett-Jones found three cases in one hospital within three months, that Weible was able to report two cases, that I have encountered two cases, leads me to believe that solitary diverticulitis of the cecum is not as rare as a review of the literature would suggest.

FUNDAMENTALS IN THE SURGICAL TREATMENT OF COLON DISORDERS*

LAWRENCE M. LARSON, M.D., F.A.C.S.
Clinical Instructor in Surgery, University of Minnesota
Minneapolis, Minnesota

SURGICAL procedures on the large bowel remain some of the most difficult of all operations in which not only to obtain satisfactory end-results but also to establish a definite standardization of technic to fit all cases. Many factors tend to produce such a condition. In colonic malignancies the concomitance of obstruction, debilitation, cachexia, anemia, and the imminence of infection, peritonitis, and hemorrhage makes any surgical attack on the large bowel an extremely hazardous maneuver. In recent years, following studies of the physiology and pathology of the large intestine, the actual technic of colon surgery has been proved to be of no more importance than the pre-operative and postoperative management these individuals receive. It is with this factor in mind as well as with accurate conception of the anatomy, pathology, and physiology of the lesions that affect the colon that this paper is concerned.

Several points in the anatomy and physiology of the colon are worth of emphasis. When one considers the function of the large bowel it becomes apparent that the organ is distinctly a double one. The proximal half is an absorptive organ and it acts in a manner similar to the small gut. Embryologically this is in keeping with the fact that the proximal half of the colon of the adult, along with that portion of the small bowel distal to the papilla of Vater, is derived from the mid-gut of the fetus. Furthermore, the superior mesenteric artery supplies the proximal

*Presented before the Upper Mississippi Medical Society at Cass Lake, July 31, 1937.

half of the colon while the inferior mesenteric artery supplies the distal half of the colon. These factors operate to produce a definite bilaterality to the colon which is furthermore reflected on the physiology of the organ. The left or distal half of the large gut has little to do with absorption, a function which is possessed by the right half, but here the bowel is concerned entirely with storage, propulsion, and expulsion of the feces. Evolution of the form and contour of the walls of the colon give further substantiation of this fact, since the proximal colon has thin walls, its lumen is large and movements here are rapid, small, churning ones. In the left side the walls are thick and muscular, the lumen is small and movements are strong, prolonged contractions which propel the contents onward to empty the colon. When disease, such as a malignant growth, attacks this organ there is consequently a difference in the effects which the lesion produces, depending on its location in the bowel. Therefore when we find an individual harboring a carcinoma of the right colon, the symptoms are most likely to be those of disturbance of physiologic equilibrium, resulting in anemia, weakness, loss of weight and so forth, yet accompanied by no visible loss of blood. The exact explanation of this anemia and weakness is not known but it probably is due to a perverted function of the mucous membrane so that abnormal absorption of toxic products in the bowel takes place.

In the left half of the colon, obstruction is the predominant symptom and this symptom results from a combination of three factors. Here the bowel content is hard and relatively incompressible, the majority of carcinomata in this location are the scirrhous encircling type and consequently obstruction takes place early. Lastly, here movements are strong and prolonged. The symptoms, therefore, are pain, tumefaction, and alternating periods of diarrhea and constipation along with flatulence and borborygmi. Finally one of the phases of complete obstruction takes place. Thus it is seen that the anatomical and physiological differences in the two arms of the large bowel play a part in determining the type and extent of the surgery which one may safely do in various parts of the colon. Probably of no less importance are these differences in making decisions as to details of pre-operative and postoperative management.

First of all it should be emphasized that malignant lesions of the bowel are, in general, slow growing, they metastasize late, and, if obstruction, exhaustion or concomitant disease does not supervene, good results may be expected from removal of the lesion. This fact has been proved by studies in which individuals dying of malignant tumors of the bowel at autopsy show metastases in surprisingly few cases. In fact, of 210 cases so studied, extension or metastases was found in only half of them, and liver metastases in only a third.

Another point of importance to remember is that diagnosis of these lesions is not, in the majority of cases, difficult. The use of the barium enema, especially with the aid of the double contrast method, has resulted in great accuracy as to the type and location of the lesion as well as its size and operability. Roentgen-ray methods along with the use of the proctoscope and sigmoidoscope should render diagnosis possible in most cases. More than half of the carcinomata involving the entire colon can be visualized by direct inspection through the sigmoidoscope or proctoscope, a fact which has been substantiated by necropsy studies of 210 individuals who died of this disease. Thus by simple means, which can be carried out in the office, it is possible to actually visualize a large percentage of these tumors.

In the pre-operative and postoperative management of individuals harboring diseases of the colon, all measures are directed toward producing and maintaining physiologic rest of the bowel so that healing without complications may be facilitated. Pre-operatively, a diet low in residue, emptying of the bowel of gas and fecal content by properly controlled cathartics, cleansing enemas, and final intestinal sedation along with supportive measures intended to improve the patient's general condition, are all intended to have the bowel at the time of the operation empty, collapsed, quiet and clean. Postoperatively, we have routinely employed, to very great advantage, continuous nasal catheter suction siphonage to prevent the entrance of air into the intestinal tract, a procedure which eliminates, to a large extent, any gaseous distention and consequent aggravation of peristalsis. After distention, nausea and vomiting have occurred, they can be relieved by this suction method but ileus is much more easily prevented than relieved. It

should be kept in mind that the extent of surgical trauma within the peritoneal cavity, the length of anesthesia and the general condition of the patient are other factors which determine the degree of ileus to be expected postoperatively. Morphine in frequent moderate doses has a beneficial effect because of its property of relieving pain, restlessness, thirst and apprehension, as well as its ability to increase intestinal tone. Its tonic effect results in maintainance of the proper absorptive function of the bowel so that toxemia is definitely lessened, since it has been proved that distention of the gut is notably accompanied by absorption of toxic products. Constipation often accompanies the use of morphine and is most likely the result of inhibition of the defecating reflex, accompanied by increase of tone of the sphincters. A compensatory diarrhea frequently develops after withdrawal of morphine and its mechanism is obvious. The most important factor in prevention of intestinal activity is the withholding of food and fluids by mouth. In our opinion, with the act of swallowing, even though it may be only a small amount of water, and especially with the ingestion of any solid food, a peristaltic wave is initiated which usually travels the entire course of the intestinal tract down to the anus. This increased activity is prone to spread any inflammatory process which may be present in the peritoneal cavity. When the propulsive power of the bowel has been regained—as evidenced by motility of gases in the abdomen, gurgling, movements, and so forth—fluids and, later, food may be administered orally. These measures, along with heat to the abdomen, are an excellent stimulus to complete recovery of normal bowel activity.

It is best, in any patient who goes without ingestion of fluids and foods for any length of time, to stimulate flow of saliva, especially from the parotic gland, by use of chewing gum, or the sucking of a lemon. This definitely lessens the incidence of postoperative parotitis. In brief, the less the swallowing, the less the peristaltic activity initiated.

Fluids, combined with saline or glucose, or both, in these cases are best administered through the intravenous route, less satisfactorily by means of hypodermoclysis. Proctoclysis, of course, in any type of colon operation is contraindicated since fluid given by this method can only be absorbed by being carried into the right colon. This could only be accomplished by reverse peristalsis, which, of course, would delay healing.

The factors mentioned have for their purpose primarily the promotion of local healing in the bowel by quieting peristalsis and increasing the tone of the bowel, but, of course, measures which increase the general resistance and condition of the patient must not be neglected, such as transfusions, large amounts of parenteral fluids, and so forth. In the immediate convalescence of the patient, after four or five days, it is wise to start, very judiciously, the use of clear fluids, then soft foods and finally, as determined by the tolerance of the patient, a diet high in calories and vitamins, but low in residue. As time goes on, the patient will find out for himself the type of food best suited to his needs.

It is thus evident that, because of the bifunctional nature of the large intestine, most diseases, especially those of a surgical nature, should be regarded differently, depending upon the location in the colon of the lesion. This especially is true when one comes to a consideration of problems involved in resections of the colon. In the distal portion of the large gut, it is usually much more dangerous to resect a segment and make a primary anastomosis in one stage than it is to first employ a drainage operation, such as a colostomy or cecostomy, and sidetrack the fecal current. On the other hand, it is relatively safer, in right colon lesions, to do a short-circuiting operation and in addition to resect the diseased area at one sitting, depending, of course, to a large extent, on the general condition of the patient and characteristics of the lesion. The factor of obstruction is rarely encountered when considering the treatment of lesions in the proximal colon. Aside from the question of relieving obstruction in left colon lesions, and of doing graded operations where the general condition of the patient comes into consideration, there still is another factor of which cognizance is not often taken. This is as described as follows.

Peristaltic movements of the distal colon, as well as anatomical conformations of this portion of the gut, are of a distinctly different nature than those of the right colon and small bowel. In the distal large bowel, the thick muscular walls

have for their purpose forceful, strong movements which are distinctly prolonged and are made under considerable tension. In fact, tonus waves here may last as long as ten to fifteen minutes. In addition there are superimposed on these long contractions smaller contractions often lasting one to two minutes. Thus it is evident that, with such prolonged tension on an anastomosis, healing would be very difficult, largely because of the local ischemia which is produced. This is further evidence as to the value of preliminary colostomy (Larson and Bargen). Furthermore, the contents of the left colon are rather hard and incompressible, and this condition, combined with relative fixation of the mesentery, tends to favor pulling apart the suture lines of an anastomosis. The blood supply in this region is not as abundant as it is in the small bowel, another factor tending to retard healing, since any tension on suture lines results in further ischemia of anastomosed margins and gives increased chance for infections to gain headway. Consequently there is a greater possibility of failure of the tissue to heal. If a preliminary drainage has been done, resection of a segment of bowel followed by anastomosis is more liable to heal satisfactorily for several reasons. The first, of course, is the side-tracking of the fecal current and the decompression of the bowel. Secondly, since a certain amount of peristaltic motion of the bowel is due to impulses traveling along the muscular layers, interruptions of these muscular fibers by cutting across the bowel in making a colostomy results in many of these waves being stopped and they cannot jump from the proximal to the distal stoma. This has the effect of keeping the side-tracked loop of gut much more quiet with consequent avoidance of tension on suture lines. It is, of course, true that the latter segment contains no fecal material and that it can be cleansed readily so that inflammatory reactions may subside and exudates may be absorbed, but the factor of inactivity is, likewise, an important one in successful promotion of healing.

It is true that the mesenteric nerves (sympathetic fibers), which run along the blood vessel, do reach the bowel wall regardless of interruption of continuity of the gut, as demonstrated in a previously published communication (Larson and Bargen). However, the main motor nerve to the colon, the pelvic nerve (or nervi erigentes), supplies only the distal portion of the left colon and this nerve plexus lies on the surface of the bowel wall between the muscular layers. Consequently, it is readily understandable why motor impulses through the gut are interrupted by section of the bowel. When reëstablishment of the continuity of the bowel is again made, coördination of the intestinal movements is usually resumed in a relatively short time with no particular difficulty, although it is rather common to find some difficulty in bowel habits is experienced for some time. A parallel situation exists in many cases of local pain occurring postoperatively after appendectomy. It is usually true, when recurrent pains are present for a time after removal of the appendix, that adhesions are considered to be the source of this embarrassing discomfort, and this is no doubt possible in many instances. On the other hand, I am convinced that, in many instances, this pain is due to interference with conductivity of nerve impulses through muscle tissue, resulting from the removal of the appendix. This has the effect of temporarily producing stasis in the proximal cecum, or at least an incoördinated motility in this region, so that pain, flatulence and other symptoms result. These symptoms frequently continue for varying lengths of time, until reestablishment of normal motility has been made.

Dangers of Protamine Insulins

Reports of reactions following the use of protamine zinc insulin have appeared in considerable number. In one of the earlier discussions of protamine zinc insulin it was reported that hypoglycemia from this type is more subtle in onset and on the whole subjective symptoms are less severe than with soluble insulin. Preliminary symptoms of shakiness, sweating and palpitation may be absent; thus severe hypoglycemic symptoms may appear without warning. Ample evidence is now available that protamine zinc insulin is not a foolproof substitute for the older preparation. Although reactions to it seem to appear with less frequency, they also are often characterized by the suddenness of onset, delayed and therefore unexpected appearance, and symptoms precipitated by exercise at such a distant time as also to be wholly unexpected. Although the development of protamine zinc insulin is an advance of unquestioned value to many diabetic patients, the possibilities of delayed severe reactions cannot be ignored. (J.A.M.A., July 16, 1938, p. 254.)

PRACTICAL PHYSIOLOGY OF THE NOSE*

HAROLD I. LILLIE, M.D.

Rochester, Minnesota

WHEN it is realized that the nose is the only portion of the body that cannot be appropriately protected from the environment to which it is subjected, it will be appreciated that in order to withstand the exposure to which it is subjected, it must have a wonderfully adaptable functional mechanism. For that reason it is important that fundamentals of the physiology of the nose be known, because in daily practice many patients are encountered who complain of symptoms referable to the upper part of the respiratory tract, which, on final analysis, are not symptoms of pathologic change, but may be explained as evidences of normal physiologic response of the structures to changes in environment.

The details of the function of these structures are not thoroughly understood by many practitioners, and apparently are not known by the laity. This is largely attributable to the fact that, in medical curriculums of the past and present, very little mention is made, and little attention paid, to the part that the upper portion of the respiratory tract plays in respiration and to the effect of this function on the general well-being of the individual. Careful study has been made by research workers on the physiologic processes referable to the special senses, olfaction, taste, and so forth, and, in turn, this knowledge has been passed on to patients. Patients do not understand how the nose and throat would be expected to function under certain environmental conditions, and they, therefore, complain of symptoms which, in reality, are of no more consequence than other physiologic bodily reactions which seem commonplace to them, such as sweating, chilling, sunburning or tanning. Usually, when the symptoms are explained on this basis, the patients are relieved and satisfied.

It is generally considered that the first serious attempt accurately to describe the anatomy and physiology of the nose can be credited to Galen, who lived in the second century A.D. Hippocrates and Aristotle had thought that the reason the nasal interior was moist was that the secretions came from the brain through the cribriform plate of the ethmoid bone. Galen subscribed to this idea. He thought that the nasal membranes were bloodless but he recognized that they were continuous with those of the pharynx and mouth. That the nasal membranes contained secreting glands was not recognized until the time of Schneider. To his credit, Galen said that the function of the nasal interior was to prevent the air from entering the trachea, directly, "First, because the air surrounding us is at times quite cold and the lungs then would be chilled; and, secondly, because small particles of dust or of ashes or anything of this kind may not fall into the trachea."

It was in the sixteenth century that open revolt against the previously accepted ideas of Galen occurred. Among the revolters was Vesalius, a Belgian, who had that attribute of genius described by Carlyle as the ability to see with one's eyes and the inability not to believe what one sees. However, Vesalius, in his observations of the anatomy of the nose and throat, committed more errors than he corrected.

Contemporaneously with Schneider, Willis felt that the fluids in the nose came through the nerves, which he considered to be tubes coming from the brain. Van Ruysch believed that nasal secretions came directly through arterioles and he did not accept the ideas on intermediary effect of glands. Schneider, in the middle of the seventeenth century, wrote voluminously. He showed that secretions in the nose could not come from the brain, through the cribriform plate of the ethmoid bone or lacerated foramina, or through the nerves because they are impervious. He found that mucus could be squeezed out of living or dead membranes but did not mention glands. It was Steno who first described mucous glands. Following introduction of the microscope and discovery of methods of preparing tissue for microscopic study, great strides were made.

Rhinology has made great progress in the past quarter century and, fortunately for patients, is now practiced on a more conservative and scientific basis than before. Formerly it

*From the Section on Otolaryngology and Rhinology, The Mayo Clinic, Rochester, Minnesota.

was largely practiced on a purely anatomic basis, and, in consequence, many patients underwent very destructive intranasal operations without their symptoms being relieved. This practice led, as Stein[16] said, to adding many new symptoms to the old. In the future, we may look for the application of more physiologic facts and, as experience grows, we may learn to see the patient as a whole rather than through the "hole" of the nasal speculum.

The function of the nose has been said to be fourfold: to warm, to moisten and to filter the inspired air, and to smell. The efficiency of each of these processes depends, largely, on the function of the vasomotor control. The special sense, olfaction, will not be considered.

General Fundamental Aspects

Certain individuals can be identified easily by the particular conformation of their noses. In fact, in police work, the nose has been used for this purpose. A well-functioning nose may not necessarily be a thing of beauty but it is a joy forever. It would be difficult to describe the external appearance of the nose in words, and rather difficult to describe its position on the face. All noses of men have one common characteristic: the openings are more nearly on the horizontal than on the vertical plane, when one lives an upright life. There seems to be a natural reason for this, the directing of the air currents into the intranasal structures, or real functioning region. To be sure, a person may live his allotted life breathing through the mouth, but he will not live so comfortably under all environments. Patients are also known to have lived twenty years breathing through a tracheotomy tube.

The indications of the nasal fossa in the embryo appear as pits, situated on either side of the anterior portion of the head, and are first seen at about the twenty-first day, the same time that the eyeball and ear vesicles appear. As development takes place, these nasal pits fuse.[10] Intranasally, the nose is divided by the septum, which is scarcely ever perfectly straight, into nearly equal cavities, opening anteriorly through the vestibule and posteriorly into the pharynx through the choana. From the lateral wall project the three turbinate bones, thereby enlarging the available surface exposure, and helping to direct the air currents within the nose. Beneath each turbinate is situated the so-called meatus, of which the middle meatus is the most important because in it, protected by the middle turbinate, is situated the hiatus semilunaris, with the openings to the paranasal sinuses. The inferior turbinate is normally the largest and tapers toward each end. Under it is the opening for the lacrimal duct. The intranasal cavity narrows as it approaches its upper extent. That portion of the nose which is below the level of the superior border of the middle turbinate may be said to be respiratory in function, and that above, olfactory. From the choana, the air enters the pharynx.

Histologically, the upper part of the respiratory tract may be said to be lined by the same type of membrane and substructures, except that in certain situations certain characteristics predominate. For instance, the mucosa is relatively thicker over the turbinates than it is in any of the other portions of the tract, and in the ethmoid cells it is relatively very thin. The lining mucous membrane is very vascular and is inseparably united with the periosteum and perichondrium over which it lies.

The blood supply comes largely from the sphenopalatine artery, which anastomoses with the ethmoidal, external nasal, septal and palatine arteries and with those which supply the lower part of the nasolacrimal duct. This network of vessels occupies the deepest regions of the mucosa and the periosteum. The veins empty into the facial veins largely but from the ethmoidal region they communicate with the venous plexus through the cribriform plate. The veins which arise around the lacrimal sac and duct empty into the orbital veins, and into those of the face around the orbit. The lymphatics are subepithelial and large.

The respiratory membrane is supplied with cavernous blood spaces of erectile tissue. The arterioles are supplied with a muscular layer and, from their deep situation, take a corkscrew course toward the surface and the venous sinuses, the latter of which may be of considerable size and so much enlarged in the mucosa, when it is the site of inflammatory change, that it is often difficult to judge what is abnormal. Development of the erectile tissue has a close relationship with the beginning of sexual life, since it is seen in its full extent only after adolescence has been established, and it begins to atrophy after middle life. This fact is of definite clinical importance in everyday practice.

The capillaries are distributed everywhere through the connective tissue of the mucosa. Tiny capillary twigs are in contact with the basal layer of the glandular epithelium, and Wright[17] has said that it is possible to see direct diapedesis of the leukocytes through the capillary walls and between the gland cells, into the lumina of the acini. There is every reason to believe that in this way the blood vessels may empty the serous and leukocytic elements of the blood directly into the glands. Vasomotor dilatation, therefore, means not only exudation of the serum of the blood vessels into the stroma, and consequent swelling of it, but simultaneously a direct discharge into the glands and onto the surface of the mucosa. Around the ducts of the glands, the mouths of which usually lie in some sulcus of the surface epithelium, there is a more or less thick network of capillaries. It is seen, then, that vasomotor dilatation of these capillaries would mean considerable constriction of the outlets of the glands. As the vasomotor excitement subsides, this constriction is released and free discharge of the content of the seromucous glands is afforded.

The contractile elements of the stroma are composed of elastic tissue and smooth muscle fibers. It will be recalled that attention was drawn to the erectile tissue and to sexual development, and it becomes clinically important that this be recognized, for it accounts for many of the so-called "stuffy noses" so often seen in adolescence and newly married couples. Innervation of these substructures comes from the parasympathetic nerves through the sphenopalatine ganglion and, as knowledge of the sympathetic nervous system and its substructures increases, it will be possible to deal more intelligently with the various syndromes that are attributable to derangement of the vasomotor control. The elastic elements are important because of the effect that repeated inflammatory reactions may have on them. Thick interlacing bundles, running parallel with the planes of the bone, are demonstrable. In the same manner, the smooth muscle cells of the blood vessels are important because of the effect that repeated inflammatory reactions, resulting in enlargements, may have on the caliber and function of the blood vessels.

The sensory nerve supply comes largely from the fifth cranial nerve. The activating nervous impulses that control what might be called the automatic responses of the nasal membranes, come through two sets of antagonistic autonomic nerves, the vasoconstrictors and the vasodilators. The vasoconstrictor fibers arise from the preganglionic fibers from the central nervous system and the postganglionic fibers from the cells of the sympathetic ganglions. These nerves exert a constant tonic effect. The efferent fibers which cause vasoconstriction are called "pressor" fibers and those that cause vasodilatation are called "depressor" fibers. The vasoconstrictors arise chiefly from the cervical sympathetic nerves. Hempstead[7] has observed marked congestion of the nasal membranes of patients who have been subjected to removal of the cervical ganglions for certain vasospastic conditions of the upper extremities.

It is known that the caliber of the blood vessels is influenced by agents other than the vasoconstrictor and vasodilator fibers. Chemical substances, carbon dioxide, histamine and lactic acid, Bayliss[2] has shown, may produce vasodilatation. Internal secretions, such as epinephrine, may cause vasoconstriction.

Whether the cells of the surface layers of epithelium are of the columnar or of the pavement variety, those of the basal layers, except for the olfactory region, are cuboidal in shape, resembling closely the fixed connective-tissue cells with which they mingle, for there is no limiting membrane between them. It is often difficult to determine where the epithelium leaves off and the stroma begins. In the olfactory region, the epithelium is nonciliated and columnar, and does not possess the glandular elements seen elsewhere. In the respiratory portion, the membrane is covered with columnar, ciliated cells and a mucous film.

In recent years, action of the cilia and movement of the mucous film have received much attention in rhinologic circles. Elucidation of these phenomena has called the attention of observers to the importance of normals and thus has had good effect. However, it can be said, without detracting from the interest of these phenomena, that the action of the cilia is only one phase of the general physiology of the nasal membranes. It has been shown that cilia, fortunately, are present in newly formed membrane following operations. It has been clearly shown by Hilding,[8] Proetz,[12] Yates[19] and others how

the mucous film and the movement of the cilia perform their function. In the sinuses the cilia have the important function of directing flow toward the ostia. The greatest good has come from exposition of the facts that the normal presence of mucus and the activity of the cilia are great barriers to infection. It is only when this mechanism is deranged that infection gains a foothold.

The Bowman type of gland prevails in the olfactory region. These glands secrete a much less viscid fluid than the racemose glands in the respiratory membrane. Although it may be true that these cells secrete a peculiar fluid which aids in the function of olfaction, its watery character is especially adapted to extend over the olfactory surface and to cause the fluid to drip down as sterile irrigation for the respiratory region below. It is not bactericidal in action.

The racemose glands of the respiratory region differ in no way from the structure of racemose glands elsewhere in the body. Not infrequently the acini are imbedded in the tissue, but, as a rule, they lie more superficially than the cavernous sinuses, varying greatly in their distribution. In the paranasal sinuses there are very few. It is said that the secretion from the respiratory part of the membrane is in itself considerably bactericidal, at least bacteriostatic.

Under normal conditions the secretions of the nose maintain a certain physiochemical composition which fluctuates within a limited range, depending on the demands of physiologic activity. This is an involved subject and the details have no place in a discussion such as this. The secretion is composed of mucin, solids, minerals and an aqueous portion. The mucin originates in the racemose glands and probably acts as a deterrent to the rapid absorption of the serous portion of the secretion; in additon to having a protective influence on the sensitive ciliated cells it has been shown that the mucus has a bacteriostatic effect.

The activity of the secretory mechanism may be observed clinically. If a patient whose nasal interior is apparently normal can be observed over a period of time, at short intervals, it will be noticed that the appearance and relative position of the membrane within the nose changes. At first one nostril may be filled because the membranes are swollen; the surface is smooth and relatively dry. In a moment or two, the surface is seen to be studded with little discrete drops of moisture. Soon the droplets increase in size and the surface begins to be covered with a film. Now it is noticed that the swelling of the membrane is less and gradually becomes much less, so that the membrane does not fill the nostril as it did. The membrane in the opposite nostril, if examined, may be found to be increasing in size. What has happened is that the blood spaces in the membrane have filled; the involuntary muscle, through stimulation of nerves is causing contraction of the blood spaces, forcing the blood into the glands and stroma, and in turn the content of the glands is expelled through the ducts onto the surface, producing the droplet that can be seen. As the activity is increased, the secretion increases until the cycle is completed. The watery, or predominant, portion of the secretion comes from the tubular, Bowman type of gland. This automatic flushing of the surface cannot be imitated by sprays and douches. Denuding of the surface subjects the sensitive epithelium to changes that are not consistent with normal conditions.

It can be observed clinically that nasal respiration is an adaptive reflex mechanism, lessening resistance when respiratory need is increased, and vice versa. Dilatation of the vessels, when it is not carried to the point of rendering insufficient the amount of air supplied to the lungs, renders the air, when it reaches the pharynx, not only warmer, more moist, and more free of dust and bacteria, but by filling the unnecessary space in the respiratory region of the nose, it directs a more copious supply of air toward the olfactory region. Wright and Smith[18] said:

> "The internal configuration of every nose, even of those we would pronounce normal, varies so greatly that every nasal chamber is a law to itself. Anterior and posterior rhinoscopy are often incapable of furnishing us with trustworthy information as to the efficiency of the nasal chambers in the performance of these functions. The statements of patients are still more untrustworthy. Some fail to appreciate even extreme grades of nasal obstruction. Others complain of it when manifestly it does not exist. The clinical experience, the common sense of the physician, and his ability to judge the patient's temperament are more important guides to the appreciation of how these functions are in reality being performed, than the help his technical skill or the instruments of precision at his disposal furnish him."

Paget[11] has said that he believed the function of the nose to be to filter the air and that the

other ascribed functions are entirely subsidiary. He expressed the belief that nearly every healthy man has lost the power to breathe through the nose because of the tendency to alar collapse, that if more respiration was nasal there would be less pulmonary disease.

Chepmell,[4] in discussing Paget's annotation, quoted Catlin's book entitled, "Shut Your Mouth," written in the early forties of the nineteenth century. Catlin was impressed by the healthiness of the American Indian children, whose mothers insisted on their breathing through their noses. Hagemann[5] expressed the belief that the function of the nose may be emunctory to a large extent. Wright has said, "Vasomotor phenomena answer to every demand of physiologic need only so far as the mechanism is undamaged in all its parts. Repeated temporary exaggerations of physiologic response lead gradually to the graver forms of polypoid rhinitis and atrophic states." Thus it is seen that the function of the nose is carried on by virtue of its internal configuration and the mechanism of its mucous membrane. As the air enters the vestibule, it takes an upward course, passes over the superior surface of the inferior turbinate, over both surfaces of the middle turbinate, and enters the pharynx. The membrane of the pharynx is essentially like that of the nose, except that it is not so specialized. In the pharynx, however, there is lymphoid tissue; such tissue is not encountered in the nose. In passing over these structures, the air currents take up the moisture from the surface, and are thus warmed, moistened, and filtered. In expiration, the air currents are directed largely through the inferior meatus by the posterior tip of the inferior turbinate. What function is served by the accessory sinuses of man is a question, but it is apparent that they are ventilated by the negative pressure effect exerted by the passing streams of air. The function of the tonsillar tissue in the pharynx is also uncertain; that it has a function in early childhood, even though it is not understood or known, I am willing to admit.

Symptoms referable to the upper part of the respiratory tract are less common and are less often complained of when persons live where the climate is warm and equable. This is because there is less necessity for the nose to overfunction in order to prepare the air for the lower part of the respiratory tract. Such a climate, however, has its definite drawbacks, as it has been shown that mental and physical productivity are at lower levels than in less equable environments. Huntington,[9] in his "Civilization and Climate," proved that the output of factory workers increases with change in temperature, and that no other elements of weather seem to have a real influence on such productivity. He explained the physical superiority of persons who live in hard, rugged climates by the subjection of their bodies to frequent and extreme alternations of temperature. The reasonable physiologic explanation of this phenomenon seems to be stimulation of the tonus of the vasomotor system.

Sewall[15] said:

> "Climate is the summation of atmospheric conditions as recorded for a long period of time, or, in other words, it is the totality of the weather, while weather is the physical condition of the atmosphere at a given time, or during a limited period.
>
> "It was formerly thought that the atmosphere affected the body only, or chiefly, through the absorption of its elements by the lungs, but it has been found that this is not the case, and that these symptoms are caused by the effects of the atmosphere on the surface of the body. . . . . In this connection, the various respiratory membranes are to be thought of as internal body surfaces, which are also brought in direct physical contact with the atmosphere. Heat, humidity, and stillness are the essentials in a bad atmosphere; coolness, dryness, and motion of the air constitute good ventilation."[1]

From what has been described as the normal physiologic reaction of the nose, it can be seen how, with a perfectly acting mechanism, particularly the vasomotor mechanism, the nose would be called on to function in different atmospheres. In the variable, rugged climate of the Northwest, with frequent changes in weather, one might expect that the membrane of the upper part of the respiratory tract would become hypertrophic, whereas, in the warm, equable climate, where the nose is not required to function excessively, there might be very little change. It is easy to understand, then, that in the north, in adolescent and early adult life, many symptoms might arise from the physiologic activity of the respiratory membrane, particularly as it is at this period of life that the function of erectile tissue is at its height. This is why many adolescents and young adults complain of nasal obstruction and excessive secretion. It has been variably estimated that the respiratory membrane might secrete anywhere from a pint to a quart

(500 to 1,000 c.c.) a day. Patients often complain of obstruction on alternate sides, but as a matter of fact this is normal. Scarcely ever would both sides of the nose be open to the same extent, for the reason that there appears to be a cycle of reaction; that is, while the mucous membrane of one nostril is filling to a point approaching obstruction, the other nostril is opening and throwing off its secretion, and by the time the nostril that is filled has completed its cycle, the other nostril has completed the opposite cycle. The reverse is also true. The cycle may not always take place to the extent described, but nearly to that extent.

At my suggestion, Heetderks[6] made observations on reactions of the nasal membranes of apparently normal persons in each of the first six decades of life, when the persons were subjected to various atmospheric conditions. It was observed that the nasal membranes of adolescents were much more responsive to environmental changes than were the nasal membranes of older persons. In about 80 per cent of cases a definite cycle of activity such as has been alluded to previously, occurred. Also, even though the environmental condition remained the same, a cycle of activity occurred; that is, while the membranes on the turbinates were filling on one side, the membranes on the opposite side were throwing off secretion. Heetderks found that when the subjects were subjected to cold air the secretion was abundant, while in warm air it was less copious and the membrane appeared duller in color.

Patients often complain of obstruction at night on the side on which they are lying. This is the result of passive congestion from gravity and is a normal condition. Complaint is also made of the accumulation of a considerable amount of secretion in the pharynx during the night. Really, the accumulation occurs because it has not been involuntarily disposed of, as it would have been during the day by involuntary swallowing and by eating and drinking. Many persons feel that this condition is detrimental to their health, but I have seen no evidence of this; it is usually the most robust type of patient who makes this kind of complaint. The laity call this condition "catarrh." With the condition of hypertrophic rhinitis superimposed on nasal obstruction caused by anatomic defect, such as a crooked septum, the symptoms are naturally aggravated. In other words, there is an anatomic obstruction and physiologic hyperactivity. Often, in this type of case, correction of the anatomic obstruction by some operative measure which conserves the membrane, will largely relieve the symptoms. If the symptoms are not relieved in this manner, a change to a high, dry climate often will effect the change by natural processes. The dryness and equability of such a climate will take up the excess secretion that the hypertrophic condition is producing, and there will be little or no variation to cause the excessive physiologic responses. It is in this type of nose that destructive intranasal operations were often performed formerly; these, I believe, are contraindicated.

Occupation has a great deal to do with the physiologic responses of the membrane of the upper part of the respiratory tract. It has been shown that examination of workers in steam laundries, who have been engaged in this type of work a long time, invariably discloses rather definite grades of atrophy of the membrane of the nose. This can be explained on the basis of climatic conditions, already discussed.

Stark[15] made observations on the nasal membranes of patients who were forced to use a tracheotomy tube because of laryngeal obstruction. During the first several days the nasal membrane was congested and the patient had a sense of fullness. After physiologic rest had been established, the congestion disappeared and the membranes were merely moist and duller in color. One patient, who had been troubled by crusting in the nose previous to the use of the tracheotomy tube, was relieved of the crusting after about a week's time. The explanation of this phenomenon must be that because there were no passing air currents to absorb the moisture, the air did not have a drying effect on the mucous constituent of the secretion.

The lumberjack, the farmer, the delivery man, and others who are constantly out-of-doors in all kinds of weather, are not so much troubled with infection of the upper part of the respiratory tract, or with symptoms encountered so often among persons who live a sedentary, indoor life. Attention to personal hygiene will, in some measure, relieve the symptoms. The city dweller has found that he must protect his feet from becoming wet or cold, or have a "cold in the head." "The man clad all day in the same kind of clothing finds that he cannot remove

any part of this clothing without the risk of taking cold. His wife wears high shoes or spats during the day, when it is warm, and has her neck and chest protected, but in the evening, attending a social function, she apparently disregards all sane principles of dress; yet it is observed that she is less disposed to catch cold than the man." This is another example of the hardening process. The vasomotor tone is better developed if one exposes the surfaces of his body and changes his clothing to suit the occasion than if one constantly dresses in the same manner. Susceptibility to the physiologic changes can be largely controlled by training; that is, the city dweller can become a farmer or a rural delivery man, and gradually acquire the same physiologic reactions, and the reverse is true.

Much has been written and said recently about the effect of relative humidity and ventilation in the home. At first, attention was given to these matters because of the economic factor; it was noticed that the furniture began to creak and come apart in the winter and that by evaporating water in the rooms this was overcome. In addition, a feeling of greater general physical comfort was obtained at a lower temperature. It has been observed that acute infections of the upper part of the respiratory tract resolved more readily when the temperature was warm and the air moist than when the environment was cold and dry, and that when inhalations of steam were used to saturate the inhaled air with moisture, pharyngeal and laryngeal coughs could be largely controlled. During the cold weather the relative humidity of the air is very low. Sleeping out-of-doors on sleeping porches has been advocated as a health-producing habit, probably because of the wonderful health of those who live out-of-doors and sleep out-of-doors; but it is not taken into account that people in the city live, during at least two-thirds of the day, in a temperature sometimes 100° F. above that to which they might be subjected at night. The change causes too great a physiologic response to be endured by a respiratory membrane not accustomed to such changes.

There is another type of physiologic reaction within the nose which is attributable to some derangement of the sympathetic nervous system, and which results in what is called "vasomotor rhinitis." It may be caused by allergy, endocrine disturbances, avitaminosis or the effect of severe inflammation, and can sometimes be controlled by removing the causal factor if that factor can be ascertained. If the causal factor cannot be ascertained readily, topical applications to the region of the sphenopalatine ganglion, as shown by Sluder,[14] are beneficial; now ionization is advocated by some observers. Brubaker[3] called attention to the physiology of sneezing. Sneezing may be the manifestation of vasomotor rhinitis. Sneezing is the normal manner of clearing the nose externally. It is customary for the human being, in order to clear the nose, to blow it in some manner, and he usually closes the open nostril and blows against the opposite nostril. It is granted that this method is effective. This creates a strong, positive pressure in the nasopharynx, and may produce untoward results, because it may cause the forcible spreading of infections to the ear or paranasal sinuses. Patients often indicate that pain in the ear followed blowing of the nose. Animals are seldom affected because their only method of clearing the nose is by sneezing.

Finally, it can be inferred, from what has been said, that in the daily management of patients it is important that an understanding of the mechanism of the function of the nasal membrane and its reaction to various environmental conditions be common knowledge and that such knowledge be considered of fundamental importance in the practice of rhinology. Only in this way can the variations caused by pathologic conditions be evaluated.

The prime purpose of any form of treatment should be, as nearly as possible, to establish the parts in a condition of "restitutio ad integrum." The patient, in this way, would be relieved of symptoms and would not have to contend with the discomfiture of having had new symptoms added to the old. Conservation of the functional mechanism of the nasal membrane can be effected in many instances if therapeutic measures are applied with this end in view.

SYNCOPE

BAYARD T. HORTON, M.D.,* L. McKENDREE EATON, M.D.
and
LODWICK S. MERIWETHER, M.D.
Rochester, Minnesota

SYNCOPE, or fainting, is usually described as a sudden loss of consciousness, which probably is the result of an acute anemia of the brain. However, as to just what happens in these cases, we do not know. In this article, we shall make no attempt to consider all of the possible causes of syncope but rather shall report representative cases of the more common types of syncope in order to make the article of practical value. One could list innumerable causes of syncopal attacks but such a list would serve no useful purpose in this article. We are concerned not only with the patient who has had a transient loss of consciousness and promptly recovers, but also with patients who have had recurring attacks. Usually, the history of the case, if carefully taken, will furnish a definite lead as to the nature of the attack, especially if some relative or friend has observed the patient during an attack and can describe it accurately. The mode of onset and character of the seizure, the presence or absence of an aura, the history of injury during a seizure as well as the concern which the patient himself has with reference to the attack represent important points to be observed in recording the history. Patients almost invariably demand, from the physician, knowledge regarding the nature of their attacks and, particularly, the outlook for the future. It is with these thoughts in mind that the following cases are presented.

*Dr. Bayard T. Horton, Division of Medicine, Dr. L. McKendree Eaton, the Section on Neurology, The Mayo Clinic, Rochester, Minnesota, and Dr. Lodwick S. Meriwether, Fellow in Medicine, The Mayo Foundation, Rochester, Minnesota.

Simple Syncope

Case 1.—A man, fifty-eight years of age, was being used as a blood donor for his wife, who had recently undergone an operation. Following the taking of his blood, he became emotionally upset and fell unconscious. He was put to bed and advised to stay in the hospital over night. The next morning he was dismissed; at this time he felt perfectly well.

Comment on Case 1.—Fainting is a functional circulatory disturbance which can easily occur if a person has an unstable vasomotor system. As a rule, it is induced by pain or the sight of blood. It is characterized by a feeling of weakness which is followed by some dimness of vision and finally by unconsciousness. The most characteristic feature of such an attack is its slow onset. The patient recovers consciousness in a few minutes and in an hour or so he feels normal.

Simple Fainting Versus Hypoglycemia

Case 2.—A minister, aged forty-eight years, came to the clinic on February 3, 1938, because of the fact that in April, 1937, while he had been brushing his teeth early one morning, he suddenly had lost consciousness and had fallen to the floor; he had struck his chin against the tiles, which had caused a rather severe laceration. He apparently had regained consciousness in ten to fifteen minutes and had felt well enough to walk back to his bed. During the attack of unconsciousness, he had had incontinence of the bowels. He had remained in bed for a week as a matter of precaution, but he had felt perfectly well. He never had had an attack of this sort before or since that time. During the following summer he had worked hard and had not taken his usual vacation. In August, he had begun to note transient periods of

complete exhaustion; these usually had occurred after breakfast and had consisted of a "let-down" or exhausted feeling. This sensation had lasted for ten to fifteen minutes, after which he had felt all right. He never had noted this disturbance before breakfast. These attacks of exhaustion had seemed to increase in frequency when he had been subjected to nervous tension. They had not been associated with physical exertion. In October, 1937, he had had a dizzy spell which had lasted for one and a half hours; during the attack he had felt weak and unsteady but had not had any definite vertigo. It was at this time that he had collapsed completely while he had been attending an important meeting where he was to have given the main address. His address had to be read by one of his assistants. After a day's rest, he had felt entirely normal.

Physical examination at the clinic revealed a powerfully built man who was 6 feet and 3 inches (190.5 cm.) in height and who weighed 225 pounds (112 kg.). He had no excess flesh. At the time he came to the clinic the values for the systolic and diastolic blood pressures were 130 mm. and 80 mm. of mercury respectively while the patient was in the recumbent position. Immediately after he had assumed the standing position the respective values were found to be 110 mm. and 80 mm. On the following day, when he was in the supine position, the respective values were 120 mm. and 84 mm. As soon as he stood up, the respective values were found to be 100 mm. and 80 mm.; after he had stood for one minute, the values were found to be 108 mm. and 80 mm. Routine physical examination and neurologic examination did not reveal any abnormality. The value for the uric acid was 5 mg. per 100 c.c. of blood and that for the sugar was 73 mg. per 100 c.c. of blood. At a previous visit to the clinic, in October, 1935, a diagnosis of gout had been made and since that time he had been following a rather strict regimen because of this condition. In the interval between his first and second visits to the clinic, the values for the uric acid in the blood had been determined at various times; these values always had varied between 6 and 6.4 mg. per 100 c.c. of blood.

Comment on Case 2. In this case the patient was primarily concerned with an explanation for the previous loss of consciousness. This was uppermost in his mind and was the reason why he made a hurried visit to the clinic. He had been seen by numerous physicians; practically every one of them had suggested that his attacks were the result of hypoglycemia. However, the value for the blood sugar during his previous attacks of exhaustion always had been 70 mg. or more per 100 c.c. He had noted that the taking of sugar or food had not prevented these attacks of exhaustion and he had not felt better after he had taken food. At the clinic the value for the blood sugar was found to be 73 mg. per 100 c.c. This determination was made at 10:00 a. m., and the patient had not taken any food since 2:00 p. m. the previous day, yet he felt normal at the time the value for the blood sugar was determined. It seems obvious that one can rule out hypoglycemia as the cause of his attack of unconsciousness. In our experience, in cases in which syncopal attacks are the result of hypoglycemia, the value for the blood sugar usually is about 35 to 40 mg. per 100 c.c. during the attacks. The patients almost invariably respond promptly to the ingestion of sugar or food and frequent feedings between meals usually will prevent the attacks. Such had not been this man's experience. The presence of an intracranial lesion has not been ruled out entirely but we are inclined to regard the condition as a simple attack of fainting, which probably was the result of an associated postural hypotension. For this reason we advised the use of ephedrine and benzedrine to see if this would not maintain the blood pressure at a more constant level. However, this patient should again be examined in the course of three to six months to see if there is any additional evidence to suggest an intracranial lesion.

Carotid Sinus Syndrome

Case 3.—A man, aged sixty-two years, registered at the clinic in June, 1937, complaining of rather unusual attacks of "dizziness" which had developed two months previously. Careful questioning disclosed that he had had a similar attack in 1931. For a short time before the patient came to the clinic these attacks had occurred three to four times a week. He described an attack somewhat as follows: Suddenly, without any particular warning, he had noted a dizzy feeling and a sensation as though he were going to fall; he had to steady himself by grasping some supporting object in order to keep from falling. He was not sure whether he had completely lost consciousness or not but he thought that if he had become unconscious it had been for only a moment or two. Most of the attacks had occurred after the patient had assumed an erect posture after he had been in a sitting or recumbent posture for some time. In one of the attacks he had vomited and diarrhea had developed. He had not been aware of the fact that moving the head in one direction or another had precipitated these attacks. He had not had any disturbance of vision or headaches.

Physical examination revealed a man who appeared normal for his age. He weighed 158 pounds (71.7 kg.). The results of general physical examination were essentially negative. The values for the systolic and diastolic blood pressures, while he was in the supine position, were 150 mm. and 85 mm. of mercury, respectively. When he was standing, the value for

the systolic pressure dropped to 130 mm. and that for the diastolic pressure dropped to 80 mm. No abnormal sensations were experienced as a result of this drop in blood pressure. Digital pressure over the right carotid sinus caused the patient to become unconscious immediately. After he regained consciousness he said: "That's the type of attack I've been having." The rate of the radial pulse was markedly decreased and the pulse was almost imperceptible. This man had been a patient at the clinic on two previous occasions. In 1931, a diagnosis of chronic cholecystitis and chronic cholelithiasis had been made. A cholecystectomy had disclosed multiple stones in the gallbladder. He had made an uneventful recovery from that operation. His second admission had been in November, 1936. At this time there had been clinical evidence of periarticular changes in both shoulders; infected tonsils and chronic prostatitis also were discovered. The periarticular arthritis apparently had followed a septic sore throat. At his third, or last, visit there were no arthritic symptoms.

Comment on Case 3.—The diagnosis was a hypersensitive carotid sinus reflex on the right side. We are of the opinion that his previous attacks of vertigo and syncope had been due to the hypersensitive carotid sinus. It is interesting to note that digital pressure over the right carotid sinus produced a typical attack, and that the patient said that it corresponded to the spontaneous attacks which he had been having. In view of the fact that the attacks had been present only for two months and that he had not been incapacitated, surgical denervation of the carotid sinus was not advised. The patient was advised to refrain from wearing tight collars and to avoid sudden turning of the head, so as to avoid pressure or strain on the sensitive carotid sinus. Smith and Moersch have pointed out that the effects of medication are not very satisfactory as far as prophylaxis is concerned. Anyone interested in this syndrome should read their reports.

Syncope Caused by Hypersensitiveness to Cold

Collapse caused by exposure to cold or which occurs while swimming has been observed in a number of instances. Horton has reported a number of cases of this condition. It usually affects subjects who are otherwise healthy. This phenomenon is illustrated by the following case:

Case 4.—A man, aged forty-two years, was under observation at the clinic in November, 1935. During the previous year, he had noted urticarial swelling of his hands when they had come in contact with cold water or cold objects. When he had been out on a cold day, an urticarial rash had developed over the exposed surfaces of the skin. On one occasion, he had collapsed while he had been swimming and had had to be rescued from the water. Physical examination revealed nothing of significance and the routine laboratory tests did not reveal any abnormality. When his left hand was immersed in cold water at 10° C. for five minutes, no swelling of the hand occurred while it was in the water, but approximately three to four minutes after the hand was removed from the water it began to swell, and in ten minutes after it had been taken from the water it was swollen so much that the patient was unable to make a fist. With the swelling of the hand, the patient felt dizzy, but syncope did not actually develop. The blood pressure had decreased from its original level of 118 mm. of mercury for the systolic and 80 mm. for the diastolic to 114 mm. for the systolic and 70 mm. for the diastolic, respectively. This drop in blood pressure was not sufficient to produce symptoms. Shortly after the patient returned home he had a most unusual experience. One morning, when the outside temperature was about 30° F. below zero, he left his home and walked or partially ran a distance of four blocks to catch a bus. After he had got off the bus, a few minutes later, he walked a distance of about one block, when he collapsed and did not regain consciousness until forty minutes later, when he found himself in a hospital with a nurse holding a bottle of medicine for him to inhale. He vomited three or four times. He remained in the hospital one day but did not regain his full strength for about one week. As soon as he regained consciousness, he explained to the attending nurse and later to the physician that his collapse had been due to hypersensitiveness to cold. We previously had warned him against undue exposure to cold and, so far as we know, he has never had a similar attack. At one time he had collapsed while he had been swimming, but he had recovered completely in twenty-four hours.

Comment on Case 4.—One of us (Horton) previously introduced a test for hypersensitiveness to cold, which was employed in this case. The test is as follows: The hand is immersed in ice water at 8° to 10° C., for five minutes. Prior to immersion of the hand in ice water, observations on the blood pressure and pulse rate are made and observations are continued at intervals of one minute while the hand is immersed in the water and for a period of twenty minutes after the hand is removed from the water. If swelling of the hand occurs after it has been removed from the water, the indication is that the patient is hypersensitive to cold. A systemic reaction is indicated by a drop in blood pressure, an increase in the pulse rate, and flushing of the face. We are of the opinion that in all cases in which this systemic reaction occurs,

symptoms of collapse would develop if the patient swam in cold water.

In 1936, one of us (Horton) reported twenty-two cases of hypersensitiveness to cold, which represented the total number of such cases previously observed at the clinic. With few exceptions, the patients appeared to be in good health. Hypersensitiveness to cold constitutes a grave menace to the unwary swimmer who is the victim of this malady, but the danger can be eliminated by adequate desensitization. In Minnesota alone, since 1920, 3,000 persons have drowned while swimming. One cannot help but wonder if some of these persons were not victims of this condition. Of the twenty-two patients who were hypersensitive to cold, fourteen had systemic reactions and eleven of the fourteen had had attacks of syncope; in nine cases the syncope had occurred while the patients had been swimming and four of the nine patients had to be rescued from the water. More than twenty-four cases in which syncope occurred following swimming have been reported in the literature, and at least nine of these persons had to be rescued from the water. Fortunately, patients who are hypersensitive to cold are amenable to treatment. Systemic desensitization to cold can be accomplished in at least three ways: first, by having the patient immerse the hand in water at 10° C. for from one to two minutes twice a day for three or four weeks; second, by the subcutaneous injection of 0.1 mg. of histamine, or less, twice daily for two to three weeks; and third, by the oral administration of histaminase.

Syncope Associated with Postural Hypotension

Case 5.—A married woman, aged thirty-three years, came to the clinic in October, 1934, for a general examination. She had symptoms of vague indigestion and said that on various occasions she had fainted, particularly if she had been lying down and had got up suddenly. This had occurred frequently when she had had to get up suddenly to answer the telephone. By the time she had reached the telephone and had said "Hello," she had collapsed on the floor. Consciousness had returned promptly and she had never hurt herself when she had fallen. Physical examination did not reveal any abnormality. Her blood pressure was taken on numerous occasions for a period of ten days, but the values for the blood pressure did not fluctuate to any very marked extent. The systolic and diastolic blood pressures were 103 mm. and 78 mm. of mercury respectively while the patient was in the horizontal position. As soon as she assumed the erect posture, the values were 100 mm. for the systolic pressure and 70 mm. for the diastolic pressure. Readings of this character were made over a period of ten days, but the greatest drop in the systolic pressure was only 5 mm. and that in the diastolic pressure also was 5 mm. The routine laboratory tests did not reveal any abnormality.

Comment on Case 5.—It seems reasonable to assume that the attacks of syncope probably were due to circulatory asthenia and postural hypotension, but we could not demonstrate marked postural changes during the short period of observation. She did not have any attacks of syncope during this period of time. She was advised to return home and to take 3/8 grain (0.024 gm.) of ephedrine sulfate two to three times a day if she had additional attacks of syncope. She is unlike the patient in Case 6 as she had had frequent attacks of syncope but there were no demonstrable changes in blood pressure when she changed posture.

Case 6.—A woman, aged forty-three years, came to the clinic in March, 1937, because of frequent attacks of dizzy spells which had been recurring at frequent intervals for the past year. These attacks had been precipitated when she suddenly had arisen from a sitting to a standing posture. Attacks of syncope apparently had not been noted, although on many occasions she had felt as though she were going to faint. When she came to the clinic the value for her systolic blood pressure was 130 mm. of mercury and that for the diastolic pressure 85 mm. No record was made as to whether the readings were observed while the patient was in the recumbent or sitting posture. Two days later, the systolic blood pressure was 98 mm. and the diastolic pressure was 60 mm. while she was in the recumbent position. As soon as she assumed the standing position, the systolic blood pressure was 95 mm. and the diastolic pressure was 58 mm. for a few seconds, but the respective pressures gradually dropped within a period of two minutes to 82 mm. and 58 mm. Slight vertigo developed at this point. As a result of the administration of 10 mg. of benzedrine sulfate three to five times a day, all of the symptoms of vertigo disappeared and she was able to walk around without any discomfort. Previous to her admission to the clinic, she had not gone out without an escort for she frequently had become so dizzy that she had been unable to walk. There are a number of features about this case which we cannot adequately explain but we are of the opinion that the attacks of vertigo were due to the low blood pressure and the associated postural hypotension. Routine laboratory studies did not reveal any abnormality. She continued the use of benzedrine and we have heard from her on a number of occasions; she has continued to be free from symptoms.

Postural Hypotension Associated with Syncope, following Operation

Case 7.—A woman, aged forty-four years, came to the clinic in August, 1935, complaining of urinary symptoms which had been present for six to seven years. During this time she had not had any attacks of dizziness or syncope. A cystoscopic examination did not reveal anything of definite significance. The capacity of the bladder was 200 c.c. A moderate cystocele was present. Under anesthesia, the bladder was overdistended to a capacity of 600 c.c.; three days later, she underwent an operation for the repair of the cystocele. After she had recovered from this operation and had been dismissed from the hospital, on more than one occasion when she had arisen suddenly from a sitting to a standing posture, she had collapsed and had fallen to the floor. Each time, she had regained consciousness promptly. It seems reasonable to assume that a postural hypotension developed following the surgical operation and that she promptly recovered from this after she had regained her strength. At no time were we able to demonstrate postural changes in the blood pressure but she did have a relatively low blood pressure following the operation; the average values were 95 mm. of mercury for the systolic pressure and 68 mm. for the diastolic pressure. The transient drop in blood pressure, which accounted for the attacks of syncope no doubt lasted for only a few seconds so that we were never able to obtain readings quickly enough to demonstrate the postural changes. The attacks ceased before she left the clinic and she has not had attacks since that time.

Comment on Case 7.—Postural hypotension is not a disease, but an expression of an inadequate vasomotor control of the arterial system, which may be associated with numerous diseases. In the average case, there is always a sharp drop in systolic and diastolic blood pressure, when a patient arises from a recumbent to a standing posture. In addition, in well advanced cases, hypohidrosis or anhidrosis, is usually present. Also, there is a loss of reflex acceleration of the cardiac rate when the patient assumes an erect posture.

Postural changes in the blood pressure are almost invariably noted after extensive sympathectomy, such as that performed by Adson, Craig and Love, at the clinic, for the relief of essential hypertension. These changes always are most marked when patients first get out of bed. They have been described by Adson in numerous articles on the surgical treatment of hypertension.

In the cases which we are reporting the postural changes in the blood pressure were relatively mild and changes in sweating, as well as the excretion of large volumes of urine at night, were not observed. When one suspects the presence of a postural hypotension, the blood pressure should be taken while the patient is in the recumbent as well as in the standing posture. We recommend that this method of taking the blood pressure should be a routine part of all physical examinations.

Arteriosclerosis of the Central Nervous System and Hypertension Associated with Dizziness and Syncope

Case 8.—A woman, sixty-five years of age, came to the clinic August 26, 1937, because of attacks of dizziness and fainting. She previously had undergone a thyroidectomy at the clinic in 1930 and had remained well until one week before her last admission. At that time she had had several attacks of dizziness which had lasted from a few minutes to two hours and she had lost consciousness on three occasions. She had never fainted before in her life. Physical examination revealed generalized arteriosclerosis and a systolic pressure of 200 mm. of mercury and a diastolic pressure of 110 mm. The results of routine laboratory tests were negative. A diagnosis of general arteriosclerosis, arteriosclerosis of the central nervous system, hypertension, vertigo and syncopal attacks was made.

Comment on Case 8.—In cases in which hypertension is associated with arteriosclerosis of the central nervous system or in cases in which arteriosclerosis of the central nervous system occurs alone, the patients not infrequently have attacks of transient unconsciousness which may be of the nature of a syncopal, petit mal, or grand mal attack. In cases in which arteriosclerosis of the central nervous system is associated with the hypertension the attacks may be the result of a vasospastic phenomenon but in cases in which arteriosclerosis occurs alone the attacks are most probably the result of destruction of the brain, which is caused by closure of smaller vessels and infarction.

Paroxysmal Tachycardia Associated with Syncope

Case 9.—A woman, aged fifty-six years, came to the clinic on May 30, 1936, complaining of pain which had occurred intermittently over the cardiac region for thirteen years. The attacks had begun with a feeling of faintness and sinking sensation; the patient had felt as though she could not get her breath. There had been some associated pain in the thorax and left arm; at first, the attacks had occurred only two to four times a year and had lasted ten to fifteen minutes, but they gradually had increased in frequency and duration until at the time of her registration at the clinic she

was having one or more attacks a day. The longest attack had lasted for three hours. Dr. A. R. Barnes said that the patient was unconscious at times during the attacks. He observed her during one of the attacks and found that the heart rate was 180 to 200 per minute; the pulse was feeble and barely perceptible. His diagnosis was paroxysmal tachycardia associated with anginal pain and syncope. Dr. Barnes said that attacks of unconsciousness associated with paroxysmal tachycardia are not a common occurrence, but that they occur often enough to be of importance from the standpoint of differential diagnosis.

Heart Block

Case 10.—A man, aged fifty-eight years, first came to the clinic on February 28, 1935, complaining of spells of unconsciousness, arthritis, and an injury of the head. The attacks of unconsciousness had first occurred in November, 1935; since then they had occurred irregularly; the frequency had varied from one attack every three to four months to one attack weekly. The attacks of unconsciousness had been of brief duration and had seemed to occur immediately after the patient had turned his head toward the left or after he had arisen from a stooping position. He had had a feeling as though a stocking cap were slipping over his head, and then he had become unconscious for a few moments. On one occasion slight muscle twitching had been noted and at another time urinary incontinence had occurred. A diagnosis of petit mal had been made and phenobarbital sodium (luminal) had been prescribed. This had not affected the attacks although he had taken as much as 6 grains (0.4 gm.) of the drug daily and had become very sluggish mentally. Routine general examination revealed that the patient had received a fracture of the skull as a result of an injury which had occurred one month before he came to the clinic, but the neurologic examination did not disclose any other abnormality. In view of the history and type of the attacks, an electrocardiogram was made and a complete auriculoventricular dissociation was noted.

Comment on Case 10.—Such transient attacks of unconsciousness may be easily confused with petit mal. The fact that the attacks had been initiated by turning the head would lead one to suspect a carotid sinus syndrome, but the diagnosis was made by the electrocardiogram. The carotid sinus syndrome is also accompanied by a slowing of the heart; therefore, one cannot be definitely sure of the diagnosis by merely counting the pulse rate.

Epileptic Seizures

Petit mal.—The petit mal seizure typically consists of a sudden loss of consciousness that lasts for a few seconds. It may or may not be preceded by an aura. Automatic activity, such as walking, may continue throughout the attack. The patient may or may not fall. When petit mal alternates with grand mal, the diagnosis of the minor seizure is obvious.

Grand mal.—Little difficulty is experienced in differentiating the typical grand mal type of epileptic seizure and other types of unconscious attacks. About 57 per cent of grand mal attacks are introduced by an aura. The aura manifests itself in many ways, but it most often is of the visceral type. The patient frequently describes it as an "all-gone feeling in the stomach" or a "hot (or cold) wave starting in the stomach." Unconsciousness quickly follows; it is prompt and complete; therefore, the patient falls and often injures himself. Unconsciousness usually is followed by a tonic phase in which the muscles are contracted, the patient is rigid, and cyanosis occurs and the veins become engorged. Generalized convulsive movements then occur. Biting the tongue, foaming at the mouh, micturition and defecation not uncommonly occur. As the convulsive movements abate, the muscles become flaccid. Examination at this stage almost always reveals that the pupils are dilated and unresponsive to light; the tendon reflexes are absent, and the Babinski's reflex is positive. In about three to ten, or even thirty, minutes after the onset of the attack, the patient gradually regains consciousness. He may then complain of headaches and somnolence. A deep sleep of several hours may follow the attack.

If the typical grand mal attack is witnessed or well described by a competent observer, little or no doubt remains as to the classification of the seizure. Often the witness is too terrified to observe accurately the sequence of events. It is always helpful and at times necessary for accurate diagnosis to observe a seizure. Attacks can usually be induced by hydration within a short time. The patient is placed in a hospital under the constant scrutiny of a trained observer. The fluid intake is increased considerably above normal, and the elimination of fluid is decreased by the subcutaneous injection of solution of posterior pituitary. This method of inducing seizures is of value when they are normally far apart and the patient is desirous of an immediate diagnosis.

Failure to realize that epileptiform seizures vary greatly from the common types leads to diagnostic errors. In our experience, atypical seizures are believed to be hysterical more often

than hysterical seizures are mistaken for epilepsy. In the following case the condition was wrongly believed to be hysterical because of the uncommon precipitating factor.

Case 11.—A young man described vaguely seizures which had followed startling situations. For example, the unexpected explosion of a firecracker at his feet had been followed promptly by loss of consciousness and convulsive movements which he could describe only from hearsay.

From previous experience, the patient expected physicians to frighten him in an attempt to produce an attack for observation. Consequently, the attempts were not genuinely startling. However, when an attempt was finally successful, dilated pupils which were unresponsive to light, and the presence of a positive Babinski's reflex, left no doubt as to the correct diagnosis.

Atypical epileptic seizures without prompt loss of consciousness, with so-called dream states in which loss of consciousness may be incomplete, with bizarre motor contortions instead of the usual tonic and clonic phases frequently lead the physician, who is unaware of these variants, to the wrong conclusion.

Classification of the type of seizure is difficult but discovery of the cause of the epileptic seizure is usually more difficult. The physician must not accept too readily the diagnosis of idiopathic epilepsy. Often, such a diagnosis is reversed by careful clinical and laboratory study.

We choose to look upon the epileptic seizure as a symptom of organic disease. True, there may be an underlying hereditary predisposition to the attack. Even so, if the precipitating cause can be detected and eliminated the patient may be relieved of seizures. The organic disease may be intracranial or extracranial. Intracranial causes include cerebral tumor, abscess, or an acute inflammatory focus. A small scar that is the result of some previous injury to the brain, may act as the epileptogenic focus. Cerebral arteriosclerosis and senile atrophy of the brain may produce convulsions. The organic disease may not be primarily intracranial. Generalized metabolic disturbances, such as tetany, pernicious anemia, and spontaneous hyperinsulinism, may produce seizures that readily are mistaken for idiopathic epilepsy. Consequently, an awareness of, and a careful clinical search for, possible etiologic factors must be undertaken. The following cases are examples of the practical importance of such a search.

Grand Mal Seizures Produced by a Meningioma

Case 12.—A professional man, fifty years of age, had had recurrent convulsive seizures for six years. They had been characterized by a sudden, complete loss of consciousness and a generalized clonic convulsion. He previously had been treated with phenobarbital sodium, which apparently had reduced the frequency of attacks. Physical examination of the head, which was almost completely bald, disclosed that the veins of the scalp were abnormally enlarged and radiating from a point which was situated to the right of the midline of the vertex. At this point the bone could be seen and could be felt to be abnormally thickened over an area which was about 5 cm. in diameter. Roentgenograms of the skull revealed thickening of the internal and external tables and increased vascularity of the skull in the region to the right of the midline of the vertex. Surgical exploration and successful removal of a parasaggital meningioma resulted in relief from the convulsive attacks.

Grand Mal Seizures Associated with Tetany

Case 13.—A boy, aged fourteen years, had had convulsive seizures for six years. They had been introduced by a tingling sensation in the left foot, which had been followed by prompt loss of consciousness and generalized convulsive movements. At times, the tingling sensation had occurred without the usual subsequent events. Roentgenograms of the head revealed symmetrical cerebral calcification of the basal ganglions. The results of pneumo-encephalography were essentially negative. Although Chvostek's and Trousseau's signs could not be elicited, the concentration of serum calcium was 6.8 mg. per 100 c.c. and that for the phosphorus was 7.2 mg. per 100 c.c. of serum. Oral administration of powdered calcium lactate and cod liver oil increased the values for the serum calcium and serum phosphorus to, and maintained these values at, normal levels. The patient has had no convulsive seizures for eighteen months and no sedative drugs have been given. Previous to the treatment of the tetany, the seizures had occurred about every four weeks in spite of the adequate dosage of phenobarbital sodium.

Pernicious Anemia Associated with Attacks of Petit Mal

Case 14.—A woman who was in the sixth decade of life was brought to the clinic for examination because of failing memory and falling attacks of several months' duration. The attacks had occurred at irregular intervals without warning and had caused the patient to fall without protection. No serious injury had resulted but the relatives had anticipated it if the attacks were not relieved. The periods of unconsciousness always had been less than one minute and no convulsive seizures had been observed. Although the concentration of hemoglobin and the erythrocyte count were only slightly decreased, a study of blood smears disclosed a macrocytosis and a tendency to increased lobulation of the

polymorphonuclear leukocytes. The gastric contents contained no free acid after the administration of histamine. These findings led to a tentative diagnosis of pernicious anemia. The mental symptoms and petit mal-like attacks were tentatively attributed to the pernicious anemia. An expanding intracranial lesion could not be excluded definitely. It was decided to treat the pernicious anemia and determine the effects of such treatment on the symptoms. After one month of intensive administration of liver extract intramuscularly, the unconscious seizures stopped and the mental symptoms improved greatly.

Hysteria

Hysterical attacks of coma are recognized by both the positive findings characteristic of the hysterical personality and the negative findings of other diseases which they may simulate. Frequently, the patient is known to have parents who are emotionally unstable. The patient frequently lives under an environmental situation that is not conducive to good mental health or he previously has been frankly psychoneurotic. This information may be helpful, but it must be remembered that such patients also are subject to organic diseases and that the symptoms of these diseases may be masked or complicated by psychoneurotic manifestations. The hysterical attacks are unlikely to occur when the patient is alone or in any situation in which serious injury is probable. The seizure is usually bizarre and histrionic; it often is accompanied by apparently purposeful movements. Friends or relatives may notice that the attacks occur only when some situation unpleasant to the patient is to be avoided. The seizures often vary from time to time, and unless the patient has witnessed epileptic seizures, the characteristic organic progression of epilepsy is not evident. A confident physician may alter the character of an attack that is in progress or he may induce an attack at will by proper suggestion. The ability to induce zones of anesthesia or paralysis by suggestion attests to the hysterical personality of the patient and allows for deductions as to the hysterical nature of the spontaneous seizures. During the attacks the patient incurs no serious injury, does not soil himself, the pupils are not fixed to light, and Babinski's reflex is negative.

We believe that emphasis on the necessity of careful clinical study to exclude organic disease is justified. Judgment made with incomplete study is often fallacious. We have seen the neurologic manifestations of diabetic acidosis, hyperinsulinism, tetanus, lobar pneumonia, and other conditions, mistaken for hysteria. Pitfalls exist in the opinion arrived at by apparently effecting a restitution of consciousness by the time-honored procedures of painful pressure upon the supraorbital nerves, a dash of cold water in the face, and vigorous slapping of the patient. Such effects may be coincident with the normal recovery from an organic seizure.

The safest criterion for diagnosis is the ability to end the attacks of hysteria by psychotherapy. Suggestion alone may be effective in relieving symptoms. If the unconscious conflicts are discovered and if the patient is led to an awareness of them, cure is likely to be much more durable than it otherwise will be.

Case 15.—An unhappily married woman, twenty-eight years of age, had had unconscious attacks and convulsions for four years. Her mother had never been strong and had been considered by herself and daughter to be gifted in divining the future. The patient believed that her seizures had been precipitated by close proximity to electric apparatus. The first seizure had followed a thunder storm, during which lightning had struck a tree near the patient. The patient had not been injured by the lightning. Since the onset of the convulsive seizures the patient had lived with her mother, to whom she was greatly attached. The mother obviously had been alarmed by her daughter's spells. The mother had done all of the cooking, as proximity to the light meter in the kitchen was believed to have induced attacks. Incidentally, the patient was a poor cook, disliked that type of work, and much of the marital difficulty had been based on the husband's dissatisfaction with the food she had prepared. The seizures could be induced at will by bringing into the room the electric apparatus used in testing for reactions of degeneration and setting it so that the oscillator made a humming sound. Although the patient writhed vigorously on a narrow examining table she did not fall off. She forcibly closed her eyes more tightly when attempts were made to open them. The pupils were of normal size and reacted normally to light. The deep reflexes were present and the plantar responses were normal. After we had explained confidently to other physicians, who were present, that the abdominal muscles were contracting and that the patient would soon sit up, such a posture was immediately assumed. The attacks ended a few seconds after the audible oscillations were eliminated, although the current still was traversing the coils.

EXFOLIATIVE DERMATITIS AS A MANIFESTATION OF MONOCYTIC LEUKEMIA (SCHILLING)

HAMILTON MONTGOMERY, M.D.* and CHARLES H. WATKINS, M.D.

The Mayo Clinic, Rochester, Minnesota

WE HAVE emphasized recently the distinction between the so-called Naegeli type of monocytic leukemia (which may be regarded as a variant of myelogenous leukemia with predominance of monocytes) and the true Schilling type (monocytic leukemic reticulo-endotheliosis) in which the cells are derived from the reticulo-endothelial cells (reticular cells[8]). Either type of monocytic leukemia may have a primary, autochthonous, cutaneous origin and either type may start out with the clinical and histopathologic features of mycosis fungoides.[4,8,11] In our previous paper we emphasized the close relationship of monocytic types of leukemia to other forms of leukemia and, in fact, to any of the so-called lymphoblastomas.[12] Two cases of exfoliative dermatitis attributable to the monocytic leukemia of Schilling were included, the first of such cases to be reported in the literature.

In the last six months of 1937, we encountered four additional cases of monocytic leukemia of Schilling associated with exfoliative dermatitis.[9] In these latter cases, changes in the blood may have preceded changes in the skin. It is becoming increasingly apparent that cutaneous manifestations, and especially exfoliative dermatitis, are a frequent occurrence in cases of monocytic leukemia of Schilling, as high as 50 per cent of the cases reported (Doan and Wiseman quoted by Lynch) having been associated with cutaneous lesions either specific or nonspecific in type. This is in contrast to the relative rarity of specific cutaneous lesions associated with myelogenous leukemia, of which Goldhamer and Barney found only seventeen instances in the literature up to 1936, including only two of a generalized eruption. We wish, therefore, to give the history of two of the six cases of monocytic leukemia associated with an exfoliative dermatitis that we have encountered at The Mayo Clinic and to discuss the cutaneous, histologic and hemocytologic findings in cases of monocytic leukemia of Schilling.

Report of Cases

Case 1.—A man, aged seventy-six years, was seen at the clinic July 1, 1937, because of an exfoliative dermatitis. In September, 1936, a vesicular lesion had developed on the palm following a game of golf. A scaling dermatitis developed over the entire hand and spread gradually to other parts of the body. Within the last month before coming to the clinic an exfoliative dermatitis had developed involving the entire trunk, extremities and face. In December, 1936, a diagnosis of lymphatic leukemia had been made elsewhere, based on the finding of 21,850 leukocytes per cubic millimeter of blood. Seventy-five per cent of these were lymphocytes. He had received superficial roentgen therapy and various types of applications locally.

Examination at the clinic revealed the presence of a generalized exfoliative dermatitis. In addition, there were diffuse infiltrations in the skin, including small nodules on the legs and areas of lichenification. Hemorrhagic bullæ were present on the hands and feet. There were impetiginous lesions about the mouth and nose and a very noticeable, diffuse, bronze-like pigmentation of the skin. Hemorrhagic lesions were not present in the mucous membranes nor was there any bleeding of the gums. General examination, including roentgenologic examination of the thorax, gave essentially negative results. Enlargement of the spleen or liver was not present. Hemocytologic studies revealed that the concentration of hemoglobin was 14.2 gm. for each 100 c.c. of blood; erythrocytes numbered 3,410,000 and leukocytes 67,400 in each cubic millimeter of blood. Eighty per cent of the leukocytes were of reticulo-endothelial cell origin. The hemocytologic picture was definitely that of monocytic leukemia of Schilling. A specimen for biopsy from the right heel showed a definite picture of lymphoblastoma and contained many monocytes, including typical grooving of many nuclei, which latter picture is characteristic of the Schilling type of monocytic leukemia. Similar findings were noted in a specimen removed from the region of the shoulder for biopsy. Repeated determinations of the number of leukocytes while the patient was under treatment varied from 67,000 to 16,000 in each cubic millimeter of blood, the proportion of reticulo-endothelial cells reaching as high as 90 per cent.

*Dr. Hamilton Montgomery, Section on Dermatology and Syphilology, and Dr. Charles H. Watkins, Division of Medicine, The Mayo Clinic, Rochester, Minnesota.

The patient showed a definite response to two courses of local and systemic roentgen therapy. The last of December, 1937, Dr. Henry Michelson of Minneapolis reported that the patient was gradually failing. The hemocytologic diagnosis remained that of monocytic leukemia of Schilling (monocytic leukemic reticulo-endotheliosis). The number of leukocytes had increased to more than 500,000 in each cubic millimeter of blood. Enlargement of the prostate gland with symptoms of obstruction developed. Ulcers appeared on the cutaneous surfaces. The patient died January 22, 1938. Postmortem examination was not performed.

Case 2.—A young man, aged twenty years, was seen at the clinic November 29, 1937, because of an exfoliative dermatitis. This had started as an area of scaling dermatitis on the thigh five years previously and had gradually spread to involve the entire skin of the body. During the past twenty months he had experienced a generalized exfoliative dermatitis. Examination revealed a universal exfoliation of the skin and, in addition, there was a generalized lymphadenopathy. He gave a history of having had a lymph node removed for biopsy some two years previously and a course of two treatments with roentgen rays had subsequently been given. Because of his age, however, it was felt that he had an atopic eczema. Various intracutaneous tests were performed with negative results. General examination revealed a slightly enlarged and tender liver. Albuminuria, grade 2, was present and a few erythrocytes were noted in the urine which could be explained most readily on a toxic basis. The hemocytologic findings on admission to the hospital were as follows: the concentration of hemoglobin was 8.4 gm. per 100 c.c. of blood; erythrocytes numbered 3,150,000 and leukocytes 16,800 in each cubic millimeter of blood; the percentages of the various types of leukocytes were as follows: lymphocytes, 8; monocytes, 5.5; neutrophils, 32; and eosinophils, 54.5. The high eosinophilia together with monocytes possessing nuclei suggesting a reticulo-endothelial cell origin suggested the possibility of Hodgkin's disease.

A specimen for biopsy from the region of the right shoulder revealed a definite picture of lymphoblastoma. There was a very definite eosinophilia. There were many large cells, some with notched or indented nuclei and others with longitudinal grooving. Although it was recognized that the presence of grooved cells suggested that the leukemia was of the Schilling type rather than of the Naegeli type, the tremendous increase in eosinophils seemed to fit in better with the Naegeli type, which most hemocytologists regard as a variant of myelogenous leukemia. True Dorothy Reed cells of Hodgkin's disease were not demonstrable nor was the infiltrate like that encountered in cases of mycosis fungoides. Further hemocytologic studies showed that the number of leukocytes varied from 16,000 to 25,000 per cubic millimeter of blood; monocytes varied from 2 to 5.5 per cent; the percentage of eosinophils present on two occasions was 54.5. There were definite immature cells of the reticular cell series developing to monocytes and further hemocytologic studies by one of us (Watkins) established the diagnosis of monocytic leukemia of Schilling.

The disease ran a febrile course with a septic type of temperature reaching as high as 100.8° F. (38.2° C.). He was given a course of treatment with filtered roentgen rays, directed toward the axilla and inguinal lymph nodes and he was sent home to take further treatment. Dr. A. C. Barry, of Norfolk, Nebraska, reported that the patient died on Ferbuary 11, 1938, the result of cardiac decompensation. Shortly after his return home from the clinic, swelling of the feet and abdomen occurred. The cutaneous condition improved but the inguinal glands became larger and more tender than they had been previously. It was believed that the mediastinal lymph nodes had become involved but circumstances prevented the carrying out of further roentgenologic studies.

Cutaneous Manifestations

Mercer emphasized that two elementary types of cutaneous lesions are seen in cases of monocytic leukemia: "(1) macules and papules which, when seen early, simulate a secondary syphilid but later become slate blue and (2) pale, shotty papules which may lie deeper in the corium and are felt more easily than they are seen." In our experience, as well as in that of others,[4,5] these two types of cutaneous lesions are not specific for monocytic leukemia of Schilling, but may be encountered in other forms of lymphoblastoma. Purpuric, hemorrhagic and bullous lesions are frequently encountered early in the course of the disease, in contrast to their usual appearance as a terminal manifestation in cases of other forms of lymphoblastoma. They may result from specific infiltrations of the skin. Ulcerative gingivitis and bleeding of the gums, which appear to be frequent manifestations of monocytic leukemia, were not associated with exfoliative dermatitis in our six cases. The development of ulcers and furuncle-like lesions is usually a late or terminal manifestation of the disorder. Loveman was the first to emphasize that the disease may begin with indurated, eczematoid plaques similar to those seen in the early stage of mycosis fungoides.

Epstein and MacEachern have recently stated that the characteristic cutaneous lesion of Hodgkin's disease is the so-called exfoliative erythroderma (dermatitis). In our experience, however, exfoliative dermatitis may be a cutaneous expression of any one of the lymphoblastomas, including mycosis fungoides, Hodgkin's disease, lymphosarcoma and various types of leukemia.

It may be either a primary or a secondary manifestation. A third to a half of all instances of exfoliative dermatitis encountered among patients more than forty years of age are the result of lymphoblastoma, but a lymphoblastomatous etiology in cases of exfoliative dermatitis must be suspected at any age, as is exemplified by Case 2. Fortunately, the histopathologic picture of exfoliative dermatitis remains that of the original benign dermatosis or lymphoblastoma causing the exfoliative dermatitis,[7] although it may not be specific as to the type of lymphoblastomatous involvement. It may be necessary, therefore, to correlate clinical, histopathologic, roentgenologic and hemocytologic data. At times, removal of a lymph node for biopsy is necessary in order to determine the type of lymphoblastoma present.

Histopathology

The cutaneous, histopathologic changes were specific for monocytic leukemia of Schilling in four of the six cases associated with an exfoliative dermatitis, and were suggestive in the other two cases. Touch smears made from the specimen for biopsy at the time of excision presented a picture identical with that of the blood smears in two cases. In the earliest lesions of monocytic leukemia of Schilling the histopathologic picture may duplicate that of mycosis fungoides, which is not surprising in that in both conditions there is involvement of the reticulo-endothelial system of the skin together with increase in Gitterfäsern (lattice fibers).

If a specimen for biopsy is taken from a well-developed nodule, plaque, or zone of exfoliation, characteristic histopathologic changes are seen. There is an infiltration ranging from a diffuse to a dense nodular character limited at times to the upper part of the cutis, but often extending to the subcutaneous tissue. The epidermis may be involved in the process as in mycosis fungoides or there may be a grenze or border zone separating the epidermis from the infiltrate. The infitrate occurs especially about the smaller blood vessels, which show proliferation of the endothelium and adventitia. The infiltrate is composed chiefly of monocytic cells of varying degrees of maturity. Indented, kidney-shaped nuclei and notching of nuclei are seen, but diagnosis rests on the demonstration of many monocytes which show a longitudinal grooving of the nucleus.[2] This longitudinal grooving is actually the result of the arrangement of the chromatin but in slides for histopathologic study appears as a hyperchromatic longitudinal groove of the nucleus.

Monocytes with longitudinal grooving of the nuclei may occasionally be seen in cases of mycosis fungoides and Hodgkin's disease of the skin. In cases of mycosis fungoides, however, there is a multiplicity of cellular types with pyknosis and karyorrhexis of individual cells and clumping of cells to form pseudo-giant cells, whereas in true cases of Hodgkin's disease of the skin, Dorothy Reed cells characteristic of this disorder are usually present. In cases of lymphatic leukemia of the skin the lymphocytic cells composing the infiltrate are smaller in size than the monocytes and lack the morphologic features of the latter. Histopathologic or even hemocytologic distinction between the Naegeli and Schilling types of monocytic leukemia may at times be difficult, especially when there is a pronounced degree of eosinophilia in both tissue and blood, as exemplified by Case 2. Histopathologic diagnosis of the Schilling type is dependent on the demonstration of numerous monocytes with longitudinal grooving of the nuclei and must be corroborated by hemocytologic studies. Because of distortion in shape and character of the cells, the result of fixation and imbedding in paraffin, a final diagnosis of monocytic leukemia of Schilling is dependent on the result of touch smears from a specimen for biopsy or on hemocytologic studies.

Hemocytology

Monocytic leukemia of the Schilling type is distinguished from monocytic leukemia of the Naegeli type by the fact that the monocytes in the former develop directly from endothelial cells, whereas in the latter they develop from the myeloblast or stem cell. The Schilling type of monocytic leukemia, like the Naegeli type, may occur in acute, subacute, chronic, and even rarely, in aleukemic phases, depending on the degree of immaturity present. In the acute Schilling type, it is often difficult to distinguish this condition from an acute leukemic reticuloendotheliosis. The distinction depends on finding a great majority of the circulating leukocytes showing a tendency to develop into cells with the characteristics of the monocyte, whereas in

leukemic reticulo-endotheliosis the predominating cell is more lymphocytic in character. Unless the predominating cell is of the monocytic type, the disease should be regarded as a leukemic reticulo-endotheliosis.

In the more chronic cases of leukemia, this distinction is readily made. In practically all cases of the Schilling type of monocytic leukemia, true reticular cells may be found in the circulating blood (Fig. 1). These cells are large, are usually much larger than the average leukocyte and have an eccentric nucleus that is almost spherical. The chromatin strands usually originate from the nuclear membrane and usually run transversely across the nucleus. These strands are very thin and are sharply distinguished from the parachromatin. Under a high power of magnification these strands are found to be made up of small granules, which when stained with Wright's stain, take a blue color. The nuclear membrane is very smooth in outline and is sharply defined. Usually one or more nucleoli are found. The nuclear pattern is so clear cut that the nucleus stands out prominently from the remainder of the cell. The cytoplasm is usually abundant, is blotchy in appearance and usually takes on a grayish-blue color when Wright's stain is applied.

During differentiation of this cell toward the monocyte, the chromatin strands become thicker and seem to bend on themselves slightly, producing what appears as a groove, running across the nucleus, which has usually become slightly elongated at this time.[8] Because grooving is so distinct and because it persists almost to the stage of complete maturity of the monocyte, it becomes a great aid in distinguishing the Schilling type of monocytic leukemia from the Naegeli type. In very acute forms of the Schilling type of monocytic leukemia most of the cells will be reticular cells with only a few of the cells approaching mature monocytes in character, whereas in the more chronic forms, only an occasional very immature cell will be found. The grooving tendency persists throughout the intermediate and mature stages. This is not usually associated with the more frequent forms of leukemic reticulo-endotheliosis.

The Naegeli type of monocytic leukemia is often regarded as one form of myelogenous leukemia because of its tendency to terminate usually as a typical myelogenous leukemia with large numbers of intermediate forms and some mature forms of all types of the granular leukocytes. The parent cell in this type of leukemia is the myeloblast and the diagnosis may be made by the recognition of this cell and the intermediate stages through which it must pass in its development into the mature monocyte. The myeloblast is a relatively large cell, containing a large nucleus which makes up a great portion of the entire cell, the cytoplasm being a relatively thin band of substance around the nucleus, if compared to the much more abundant cytoplasm of the reticulo-endothelial cell. The nucleus of the myeloblast has a very thin nuclear membrane, the chromatin is usually granular, but it may occur in very fine strands. With Wright's stain, the chromatin is blue and is in very sharp contrast to the pink-staining parachromatin. The chromatin is usually in a sieve-like arrangement and is somewhat in the background, the parachromatin predominating.[2] This sieve-like chromatin structure is very char-

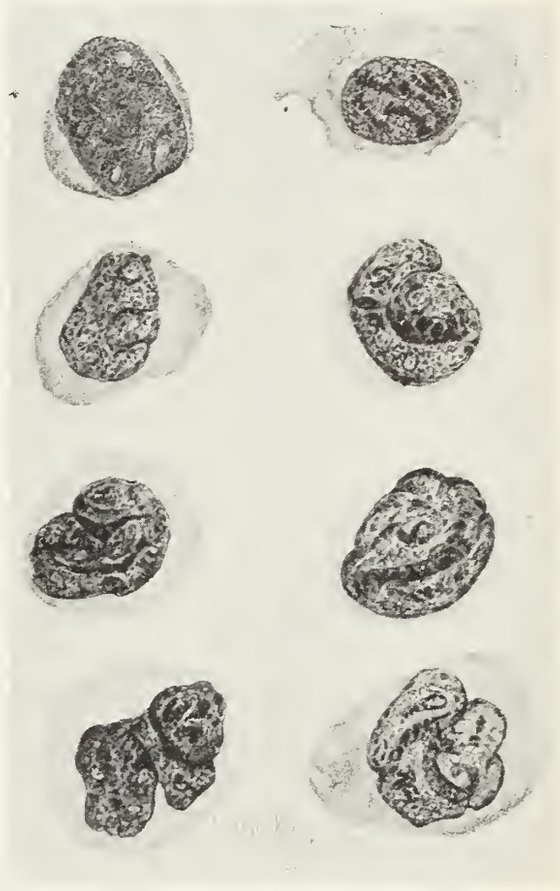

Fig. 1. Differences between the various types of cells in monocytic leukemia; the left column, Naegeli type, from top to bottom illustrates the changes from the myeloblast to the relatively mature monocyte. The right column, Schilling type, represents stages in development from the reticular cell to the mature monocyte. (Reduction of colored illustration from first article on monocytic leukemia. Arch. Int. Med., 60:51-63, (July) 1937.)

acteristic of the myeloblast and differs greatly from the pattern seen in the nucleus of the reticulo-endothelial cell. Several nucleoli are present. During the stage of differentiation, the nucleoli disappear, the chromatin becomes more prominent and there is a gradual development of the string-like clumps of chromatin that are so typical of the mature monocyte. Concomitantly, the cytoplasm gradually loses its bluish tint and becomes slate gray in color, so characteristic of the mature monocyte.

One is not justified in making a diagnosis of the Naegeli type of monocytic leukemia unless the myeloblast has become differentiated into monocytes to the practical exclusion of the other myeloid leukocytes. In an occasional case, there may be only a slight predominance of monocytes, and in such a case it would be better to make the diagnosis of myelogenous leukemia. It is probable that the Naegeli type of monocytic leukemia is a variant of myelogenous leukemia but it seems, in the light of our present knowledge, that the diagnosis of the Naegeli type of monocytic leukemia is justified when differentiation of the myeloblasts through intermediate forms into monocytes occurs, to the practical exclusion of other myeloid leukocytes.

Prognosis and Treatment

Any type of leukemia eventually proves fatal, but it is the impression of one of us (Watkins) that the Schilling type is a more benign form than the Naegeli (myelogenous) type of monocytic leukemia. The two patients referred to in this paper have died, but the other four patients who had exfoliative dermatitis associated with a monocytic leukemia of Schilling were still living in February, 1938. In all six cases there was a history of cutaneous lesions of various types appearing on the extremities, including the face, months to years before the disease was recognized. Thus, in Case 3 of our first paper, cutaneous lesions developed on the arms and thighs in March, 1931. When the patient was seen at the clinic in April, 1935, the clinical and histologic picture was that of mycosis fungoides, although in retrospect many monocytes typical of the Schilling type of leukemia were demonstrable. The characteristic picture of exfoliative dermatitis and of monocytic leukemia of Schilling was present when the patient was seen in June, 1936. There has been some improvement in the cutaneous condition since then.

In Case 4 of our first paper, the patient, a young woman, has had a generalized exfoliative dermatitis since April, 1933, which was diagnosed elsewhere as lymphatic leukemia, and then on examination at the clinic in April, 1935, as a monocytic leukemia. The patient has recently shown features of both conditions. The long duration of the dermatitis in these two cases might possibly be explained on the basis that the condition started out as mycosis fungoides and lymphatic leukemia, respectively and, later, evidence of monocytic leukemia of Schilling developed. It does seem, however, that these six patients who have exfoliative dermatitis tend to run a relatively benign course. Case 2 (Case 3 in a previous report[9]) is the only one in which there was any evidence of enlargement of the liver or spleen or a febrile course, all of which signs are frequently encountered in cases of monocytic leukemia of Schilling and may occur independent of any cutaneous lesions.[10]

The treatment of monocytic leukemia of Schilling, like that of other forms of leukemia, is only palliative and consists essentially of radiotherapy. High voltage roentgen therapy or radium therapy is indicated if the process is not too acute, but the dosage should be given with careful observation of the hemocytologic changes in order to determine the resistance of the cells to treatment. Moderate rather than intensive dosage usually gives the best results. The cutaneous lesions frequently involute temporarily, after superficial local roentgen therapy, or indirectly as the result of systemic high voltage roentgen therapy. In the cases of very acute leukemia, treatment is of no avail.

Summary and Conclusions

Exfoliative dermatitis in our experience is a rather frequent cutaneous manifestation of monocytic leukemia of Schilling. It has not been emphasized as such in recent articles in the literature. There are various other types of cutaneous manifestations of monocytic leukemia. The clinical, histopathologic and hemocytologic findings in six cases of exfoliative dermatitis associated with monocytic leukemia of Schilling are briefly referred to. A specific cutaneous pathologic picture is frequently encountered. The hemocytologic distinctions between the Schil-

ling and Naegeli types of monocytic leukemia, however, are diagnostic. It is important to distinguish between these two types of monocytic leukemia because of their different prognosis and response to treatment.

ARTIFICIAL IMPREGNATION

R. T. SEASHORE, M.D.
Duluth, Minnesota

ARTIFICIAL impregnation is fertilization resulting from the artificial transfer of active semen from the male to the female.

The literature on this subject is chiefly foreign. Since 1902 there have appeared only twenty-four articles in the American literature, and among these the case reports are not numerous. With this in view it was considered worthwhile to present a brief review of the available literature, and also to present a case in which artificial impregnation was successfully carried out.

The first reference to mammalian artificial impregnation is that of a 15th century Arab chieftain who desired to sire his mare by an enemy chieftain's prize stallion. Unable to do so, his men managed to steal some semen from the stallion, which was then inserted into the mare's vagina. Successful impregnation is said to have occurred.[6]

However, the first authentic and recorded report came from Spallanzani, in 1780. He recorded an artificial impregnation of a Spaniel bitch, as a result of which she bore a litter of four pups.[1]

John Hunter, early in the 19th century, made the first recording of artificial impregnation in the human. In his case the husband suffered from hypospadias, and coitus was impossible. The semen was collected artificially and transferred to the wife's vagina, conception resulting.[2]

From 7 to 10 per cent of marriages are reputed to be sterile. With that in mind, the procedure as here described is occasionally justified to bring family happiness to an otherwise childless couple who have the requisites of good parents.

Who should be submitted to this procedure? First, we should use this opportunity to practice good eugenics, and encourage the procedure only in those who are apt to improve society. Second, it should be done only in those cases where both the husband and wife are desirous of the procedure after due consideration.

Biologic indications include male infertility due to hypospadias or other abnormality, or to aspermatogenesis from any cause. Indications from the female standpoint, assuming that the tubes, ovaries, and uterus are normal, include stenosis of the cervix, dyspareunia, abnormal vagina, and chemical incompatibilities with the sperm.

An effort must first be made to procure, if possible, a normal impregnation by correcting any abnormalities, improving the general health, changing the vaginal flora and chemical reaction, stimulating spermatogenesis with hormonal therapy, and by whatever other means are indicated. Of course, the procedure should never be carried out in the presence of tubal or cervical infection.

And, we may add, the unfit from a social or eugenic standpoint should not be submitted to this procedure.

Legal Aspects

The attorney, who served in the case to be presented, found no mention of any ruling or any discussion of this subject in the legal literature. Consequently moral dictates must be our guide in handling these cases. Also, it is advisable to use the utmost legal precaution for all concerned.

When the husband himself is the source of the sperm, the legal aspects are not great, but even so it is wise to have a signed statement acknowledging understanding of the procedure and willingness to comply. However, in the case of the sterile husband, where the sperm is obtained from a donor, obviously legal entanglements of a greater variety can arise. Anyone contemplating this procedure should certainly read the excellent article of Seymour and Koerner in *The Journal of The American Medical Association* for November 7, 1936, in which they discuss the legal, moral, and psychologic aspects of the procedure very thoroughly.[9]

Among the entanglements that may arise are accusations of adultery. The husband, having proof of his sterility at the time of conception, may use his wife's pregnancy as grounds for divorce. He may refuse to accept the responsibility of supporting the child. The donor might claim the custody of the child. The child's status in the settlement of an estate might be questioned. The child could even claim a share in the donor's estate.

The procedure, of course, should not be done unless there is an intense desire for a child on the part of the wife, and the husband is entirely agreeable. It is wise to delay several months in order to be certain that it is not merely a hasty and transient desire on their part. During this time the husband and wife could be treated in an attempt to establish normal conception.

For the protection of everyone concerned, legal papers should be drawn in which the wife and the husband accept full responsibility for the procedure, and also accept the child as their legal offspring. Seymour and Koerner, in the above mentioned article, present this excellently worded consent statement to be signed by the husband and the wife:

"I, ..., residing at ..... of my own free will and volition have requested Dr. ..... to inseminate my wife artificially with the sperm of a male selected by Dr. ..... This request has been made with the full knowledge and consent of my wife, whose authorization is hereto annexed. I am making this request, because it is not possible for me to procreate and because both my wife and myself are extremely anxious to have a child and because our mutual happiness and the well being of my wife will be best served by this artificial insemination.

.....(LS)

On this ..... day of ..... 19...., before me came ....., to me known and known to me to be the person described herein and who acknowledged to me that he executed the foregoing consent.

.....(LS)

I, ..., join in my husband's request above stated and hereby authorize Dr. ..... to inseminate me artificially with the sperm of a male selected by Dr. .....

.....(LS)

On this ..... day of ..... 19...., before me came ....., to me known and known to me to be the person described herein and who acknowledged to me that she executed the foregoing consent.

.....(LS)

If the people involved are strangers to the physician they also recommend that the thumb prints be placed alongside their signatures to further identify them, thus further reducing the possibility of trickery through false identification. These consent records, made in duplicate, are then sealed and filed away in separate safe places, to be available and unsealed only in case of legal complications.

It is well to have a separate consent statement signed by the donor accepting release of the child from his custody, and waiving all claims to it. It also is then filed away separately. If the donor is married, his wife should also sign the document to prevent her from later accusing him of adultery, and to minimize any possible family discord which might result.

Will the child be a legal heir, or must he be adopted by the father through court procedure? Inasmuch as no legal ruling states that he is not a legitimate heir, it is fair to assume that the consent signatures of the husband and wife are sufficient to legalize him.[9]

Psychologic Aspects

The process should be kept as secret as possible, the minimum number of people knowing of the affair, and after conception nothing should be said about it in order that the couple may more readily forget the artificial character of the conception. Likewise the donor should be one who is unknown to them, and one who is not apt to encounter them in any way. They should be told that the donor is in excellent health, and that he resembles the husband in appearance and temperament, all this to encourage the association of the child with the husband rather than the donor and thus to diminish the possibility of estrangement of affections.

Psychologic influences of a lesser degree may rest on the donor also. If he knows who the child is he may develop affection for the child, and even to some extent for the mother. Even if he does not know the child, his thoughts may wander in that direction and influence his mental makeup.

For the good of the child, he should be kept in ignorance of the affair, at least until he is able to meet the knowledge with intelligent understanding.

Selection of the donor should be done carefully. He should be someone of the same nationality, physique, appearance, and temperament as the husband, so that if the donor's characteristics are dominant in the child they will resemble the husband's as nearly as possible. Naturally, he should be in good health, both physically and mentally, and of good family heritage. The donor should be advised to keep the affair secret so that it will not arise on later occasions to plague him.

Objections to the procedure may be esthetic, psychologic, and moral attitudes. However, any couple really desirous of a child will willingly overlook these things after they are fully explained. Objections on the part of prospective donors may be even harder to handle. Finding a good donor may be the hardest part of the task. Other objections are complications such as infection and tubal and abdominal pregnancy which might conceivably occur. However, careful technic should make this risk no greater than normal impregnation. Mental shock after the pregnancy occurs must be thought of as a possibility, which suggests that the procedure should not be carried out in any individual who might be subject to mental unrest.

Technic

The semen is collected from the husband or donor either by frictional ejaculation or by vesicle massage into a sterile vessel. It could be collected also by coitus interruptus or by condom specimen but these methods are less aseptic. The semen should be examined to be certain that the spermatozoa are present in large numbers (about 1,000,000 per c.c.), active, and not over 20 per cent are dead or abnormal.[2] Attempts at placing the donor's semen into the vas or vesicles of the husband have not proven successful.[10]

The woman prepares herself with a cleansing douche and is placed in the lithotomy or the knee chest position. The spermatic fluid is then instilled by means of a Eustachian catheter and a syringe into the vagina, cervical canal, or uterine cavity, the latter probably being the most effective. Various authors recommend the use of from 0.1 to 1.00 c.c. of the spermatic fluid. It should be done slowly and gently, observing aseptic precautions carefully. The patient is kept lying down for a short while afterward.

Just before or at the time of ovulation is the time of choice for carrying out the procedure. The methods for determining this will not be mentioned here except to state that in the twenty-eight day cycle, anywhere from the tenth to the fourteenth day after the onset of menses will probably be right in most cases.

If failure occurs it is justifiable to repeat the process several times inasmuch as ovulation may have failed to occur within the few days following insemination, due either to delay or failure of the descent of the ovum.

Case Report

The case to be presented is that of a couple who were childless after six years of married life. No pregnancies had occurred. The wife had been in good health except for scarlet fever when thirteen years old, complicated by acute nephritis which cleared up, and for three attacks of rather severe cystitis. The husband had always been in good health except that he was sterile as a result of orchitis complicating mumps. Attempts to stimulate spermatogenesis in him by general care and Antuitrin "S" over a six months period had failed only an occasional dead spermatozoön being found in the specimen.

At their suggestion it was decided to impregnate her artificially with the sperm of a donor. I delayed them for several months, giving them plenty of time to think

it over. Legal papers were drawn and filed away in safe places that they know of and will have access to only if necessary. A donor of good health and family was selected, with the precaution that he was unacquainted with the patient or her husband.

A specimen of spermatic fluid was collected by the frictional ejaculation method into a sterile container, and was then examined and found to have an adequate number of active spermatozoa and a minimal number inactive and abnormal.

The recipient, having prepared herself with a cleansing douche before coming to the office, was placed in the lithotomy position, the cervix exposed in the usual manner and painted with a mild antiseptic. One-half c.c. of the spermatic fluid was then instilled into the uterine cavity with the aid of a syringe and a Eustachian catheter. She was kept lying down for a half hour and then sent home. She promptly became pregnant and has since that time been delivered of a normal child.

Since the time of the insemination not a word has been said about it to this couple. To all appearances they are a happy father and mother and betray no evidence of regret on their part.

MODERN TREATMENT OF BURNS

An Evaluation of Various Methods Used in 968 Cases in the Cook County Hospital

KARL A. MEYER, M.D., F.A.C.S., and J. LESTER WILKEY, B.S., M.D.
Chicago, Illinois

SINCE Davidson[7] suggested that tannic acid applied to burns forms a protective crust, the treatment of burns has been greatly simplified. When treating burns, whether they be severe or moderate, a definite program must be maintained if success is to be achieved. Regardless of the program decided on, we must plan to:

1. Treat the initial shock
2. Prevent absorption of toxins from the burned surfaces
3. Combat fluid loss
5. Shorten the period of disability by promoting healing
6. Avoid permanent deformity.

During the past decade various types of treatment have become popular, and many different dyes, antiseptics, and escharotics have been used.

In the Cook County Hospital we treated 968 burns from 1933 to 1937 inclusive. Some were superficial burns, others second degree burns, but a greater number were severe third degree burns, widespread over the body. We have had occasion to use almost every type of treatment. In this paper we shall attempt to evaluate the various treatments as used by the surgical services of this hospital.

Treatment of the Initial Shock and Toxemia

The patients that we see, or at least a great percentage of them, are in shock and are very toxic. One of our great problems is to bring the patient out of the shock and to lessen the toxemia. This brings up the great present day controversy as to whether the morbidity and the mortality that occurs in patients with burns is due to the absorption of a toxic substance formed at the site of the burn, to the loss of body fluids through the open skin surfaces causing gradual dehydration, or to the toxemia from absorbed products of infection which occurs in the burned areas.

Underhill,[15] in 1923, showed that patients with extensive superficial burns might have a blood concentration of 209 per cent of the normal. He felt that all of the symptoms following severe

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1938.

burns could be accounted for by this marked blood concentration.

Davidson[7] claimed that a toxin was formed at the site of the burn, the absorption of which caused a constitutional reaction.

Rosenthal[12,13] in a series of experiments showed that a substance was present in the blood of burned humans, a burn toxin, which was capable of lowering blood pressure, and he demonstrated that this burn toxin could be neutralized by the serum of healed burned shoats, pigs, and humans.

Kapsinow's[9] experiments, on the other hand, showed that toxins are probably not absorbed from the burned site. He was not able to find evidence of absorption after applying strychnine and phenolphthalein to burned areas.

Wells[16] states that there is increasing proof that bacterial infection rather than proteolytic toxins is the cause of death in the severely burned.

Aldrich[1] popularized the rôle of infection in burns and showed that the toxemia of a burned patient was not due to the absorption of a burn protein, or a shifting of the water balance, but to an invasion of the body by virulent forms of streptococci which entered through the burned areas.

Regardless of whether it is a toxin, an infection, or loss of vital tissue fluids, the possibility of the presence of one or all of these factors must be considered and combated.

A rule that we adhere to strictly is that any patient who has had one-eighth or more of the body surface burned is treated for shock whether it is present or not. Regardless of the local care of the burn, the shock must be combated first.

We find that shock following burns is best treated by:

1. Administration of morphine for control of pain.
2. Intravenous administration of saline and glucose.
3. A heat cradle to the body, with enough light to maintain constantly a heat of 90 degrees.
4. Blood transfusion.
5. Stimulants, when necessary.

The morphine is given in sufficient quantity to control pain and restlessness. The saline and glucose mixture is given to replace the lost blood chlorides and to bolster the liver. We give, as a rule, 1,000 c.c. of saline and glucose per 25 pounds of body weight in twenty-four hours. Some of the members of our staff add gum acacia to the saline and glucose mixture.

Blood transfusion is a routine procedure for patients in shock. The blood bank system in the Cook County Hospital makes it possible for the patient to receive blood as soon as thirty minutes after admission to the hospital. We feel that the immediate accessibility of the blood to these patients who are severely burned, has materially aided in lowering our morbidity as well as the mortality rate.

The Control of Fluid Loss

The loss of blood plasma and the concentration of blood is probably the cause of death in the first twenty-four hours. The dressing of choice must be the one that will prevent the loss of fluid from the blood stream by adequately sealing the open surfaces.

The Tannic Acid Treatment

In 1925, Davidson suggested the use of tannic acid in the treatment of burns. He showed that tannic acid would precipitate the broken down tissue proteins and close off the capillary beds, thereby preventing the loss of body fluids.

In the past ten years, tannic acid has been used very successfully in the Cook County Hospital in the treatment of burns.

When the patient comes out of the initial shock the wounds are cleansed of grease, dirt, and grime. Most of the burns that we see are covered with oils and grease. If the patient is not in shock, he is placed in a bath tub of warm water containing sodium bicarbonate. The bath tub is scrubbed daily and kept covered to prevent further contamination of the burns. The surgeon and his assistants wear caps, masks, sterile gowns and gloves. Fat solvents, such as benzine and ether, are used to remove the grease and oil without undue scrubbing. The unburned skin surrounding the wound is scrubbed with soap and water. The burns are washed with white soap and a solution of boric acid. We use white soap instead of green soap, because green soap was found to be more irritating (Koch).[10] The burned area is thoroughly débrided after the initial cleansing. In a majority of the cases the blisters and blebs are widely opened under aseptic technic using sterile instruments, and the loose areas of skin are removed. We believe that

opening of these blisters removes the fluid which contains the organisms that may later cause infection. The patient is placed on sterile sheets.

The burned areas are then sprayed with a 5 per cent aqueous solution of tannic acid every fifteen minutes until a dark mahogany colored coagulation is obtained. The heat cradle with enough light to produce a heat of 90 degrees is then placed over the body. Sheets are placed over the cradle. The coagulum is allowed to remain in place until it becomes loose or its edges curl up as healing occurs. When this happens it is cut away. If serum collects underneath the crust, as may occur when there has been complete destruction of the tissues, or should infection cause its loosening, the coagulum is removed sufficiently to allow for drainage or subsequent treatment.

From the latter part of 1933 to 1937 inclusive, 272 patients were treated by this method. Of this number thirty-four died, giving a mortality rate of 12.1 per cent. One hundred and eight showed infection.

The Compound Aniline Dye Treatment

In 1929, Aldrich[2] took cultures from the burned areas and from the serum of the blisters following burns. In all patients who were severely burned, he found growths of streptococcus hemolyticus as well as other organisms. He found that the persistent presence of these organisms was in direct proportion to the severity of the toxemia, as well as the signs of sepsis.

Aldrich felt that the success of tannic acid depended on whether or not the burn to which it was applied was sterile. He stated that if a burn is to be sealed and if this sealing is to carry out its function of preventing fluid loss, infection beneath this sealing must be avoided. A great number of infections beneath the tannic crust were being reported. So Aldrich looked for a new escharotic that would be antiseptic and nontoxic. He finally decided on gentian violet. Gentian violet is a specific antiseptic for gram positive organisms but its weakness is that it has no effect on the gram negative organisms. He developed a compound of aniline dyes using gentian violet, three parts by weight, brilliant green, 2 parts by weight, and neutral acriflavine, one part by weight. This mixture is known as "Aldrich Dye Mixture." Two grams of this mixture are dissolved in 100 c.c. of water and used in the form of a spray.

We have used the Aldrich treatment in 104 cases. Our routine is as follows:

No preliminary clean-up is done unless the patient has been treated previously with grease, oils, or ointments. If so, then these are removed by soft sponging with ether. Under strict asepsis the blebs are opened and the loose skin cut away, but no extensive débridement is done. The patient is placed under a heat cradle and sprayed every hour by means of an atomizer. An eschar develops in about eight hours.

Continual watching of the crusts are necessary. This crust does not hide infection as does tannic acid but becomes moist if there is any underlying pus.

If infection develops, the softened areas are excised, the underlying area is dried with a sterile sponge and the dyes reapplied. This technic is continued until good granulations form. One annoyance is that the dyes stain the bed linen which necessitates frequent changes.

We used this treatment in 104 patients with second and third degree burns of the abdomen, trunk and extremities. Of the 104, nine died (a mortality of 8.7 per cent) and only ten became infected.

The Gentian Violet Treatment

Following the suggestion of Aldrich,[1] we treated 125 burns with a 1 per cent aqueous solution of gentian violet. Most of the burns treated by this method were second degree burns of the extremities. It was used on both clean and contaminated burns after sufficient débridement and removal of greases and oils was done. Strict asepsis was adhered to. The gentian violet was applied by means of sterile cotton pledgets. The patient was then put under a heat cradle. Of the 125 cases treated by this method, there were only two deaths or a mortality of 1.6 per cent. There were twenty-two infections.

The Tannic Acid-Silver Nitrate Treatment

In 1935, Bettman[3,4] introduced the tannic acid-silver nitrate treatment of burns. He believed that while the tannic acid treatment of Davidson was the height of advancement in the treatment of burns, it was not entirely satisfactory because

1. It takes the solid coagulum of tannic acid hours to form, while with silver nitrate added, it take minutes.

2. As the coagulum slowly forms, the loss of circulating body fluids continues, and this loss

must be made up by repeated administration of parenteral fluids, thereby disturbing the patient frequently. With tannic acid followed by silver nitrate, one thorough application of the medication is all that is necessary for a good solid coagulum to form, and the loss of body fluids is stopped immediately.

3. By preventing dehydration, shock is minimized, and this tends to carry the patient safely through the most critical period, the first twenty-four hours following a serious burn.

This treatment is used to a great extent in the children's surgical division and Hedin[12] used this treatment in eighty-two consecutive cases with six deaths (a mortality rate of 7.3 per cent).

To effect a good result with this treatment, all grease and oil must be removed. This is accomplished by benzine. The burns are then dried by an electric dryer. Then, under strict asepsis, and with the patient on sterile sheets, a 5 per cent tannic acid solution is sprayed on by means of an atomizer. Immediately following the single spray, silver nitrate in 10 per cent solution is applied to the surface by means of cotton pledgets. The formation of a crust is accomplished in a few minutes and the crust is a flexible one. The patient is placed under a heat cradle. Fluids are forced orally and parenterally. Blood transfusion is given routinely.

If the crust becomes loose it is removed. Unhealed areas are treated by the application of oxyquinoline sulfate (scarlet red) as suggested by Bettman.[4]

The cases in which this treatment was used were severe second and third degree burns. Since January, 1938, we have treated 220 burns by this method. There were nineteen deaths (a mortality of 8.6 per cent). Of the 220, only eighteen became infected. Our records show that the period of hospitalization with this treatment is definitely shorter than that of patients treated by other methods. We also noted that the amount of scarring and deformity is reduced to a minimum by this treatment.

The Methyl Rosaniline-Silver Nitrate Treatment

In 1937, Branch[6] introduced the methyl rosaniline-silver nitrate treatment of burns. He used a 10 per cent solution of silver nitrate, which acts on the proteins of the burned area, to immediately lay down a milky white coagulum. This took the place of tannic acid in coagulating the proteins and preventing fluid loss. The methyl rosaniline stained this coagulum violet and aided in destroying and preventing infection.

After the application of the methyl rosaniline which is sprayed on in 1 per cent solution, the patient is placed under a heat cradle. The patient is resprayed five times at fifteen-minute intervals. If necessary, the spray is used once or twice daily following the initial treatment. If any coagulum remains at the end of two weeks, it is soaked off by the warm sodium bicarbonate bath. When the crusts are soaked off, epithelial islands are present in many of the cases. Scarlet red ointment is then applied.

Skin grafts were not needed in any of the cases on which this treatment was used. We used this treatment in twenty-six cases of second degree burns of the extremities. There were no deaths and only two became infected.

The Cod Liver Oil Treatment

Steel[14] of England found that crude cod liver oil, when used from the beginning of the treatment on burns, caused speedy recovery and it transformed indolent areas into healthy granulations.

We used this treatment on thirty-eight cases of first and second degree burns. These burns were not very extensive. The crude cod liver oil was applied after the burns were debrided and cleansed with warm boric acid solution. In the first degree burns, healing was fast, and the results were gratifying, but on the second degree burns, of which there were twenty-six, eight became infected, and in a large number, healing was delayed. A disadvantage of this treatment is the persistent presence of the fish odor about the patient. There were no deaths with this treatment.

Treatment of Severely Contaminated Burns and Those Over Ten to Twelve Hours Old

It is a rule in the Children's Surgical Division to treat burns which are ten to twelve hours old, or those severely contaminated with greases, oils, and dirty clothing, so that infection is assured, with moist saline dressings, or moist boric acid dressings. This establishes drainage and cleans the burned area. These dressings are changed three to four times daily and the burn is washed at each changing with white soap.

In many cases Xeroform* strips are used. These are strips of gauze treated with sterile vaseline containing 3 per cent Xeroform. These strips are changed daily. The burns are cleansed at each changing with boric acid and white soap. The strips are covered by sterile dressings and a sea sponge is placed over these dressings so that the burn only will receive the benefit of the dressing. This is done to prevent maceration of the surrounding healthy skin. The sponge is held in place by a binder. The sponge pressure is also useful in preventing the formation of excess granulation tissue.

We used this treatment in 186 cases with two deaths (a mortality rate of about 0.6 of 1 per cent). With this treatment the period of hospitalization is definitely much longer than that with other treatments, but the morbidity and mortality rates are much lower. The scarring and deformity are not of a high degree.

We have also used Amertan† on many first degree burns and some second degree burns. The results were satisfactory in that infection was not commonly seen with this drug and healing seemed to be quite rapid.

General Care of Burn Patients

At this point we must stress the importance of adequate nursing care. The outlook for a burn patient, like that of a patient following a major surgical procedure is dependent, in a great part, on the nursing care. She must see that the fluid intake is maintained, that the patient is comfortable and has adequate rest. The dressings are kept clean so that infection can be minimized.

Daily urine examinations are made on all burn patients. Blood chemistry examinations are made twice weekly to determine the blood chloride content and kidney function.

If, in spite of all precautions, infection develops, and it does in some, the patient is placed in a clean tub of warm water with sodium bicarbonate added. This is a daily procedure. Moist boric acid or saline dressings are then applied following the suggestion of Blair and Brown[5] who stated that these dressings arouse the resisting and fighting forces of the neighboring tissues, alleviate pain, and promote drainage. These dressings are moistened frequently, but not excessively so that they do not dry in place. Excessive moisture causes maceration of the surrounding tissues.

Excessive granulation is combated by the use of adhesive strips placed across the burn.

Nourishing food and tonics are given to all patients, and if the response of the patient is not as quick as expected, a blood transfusion is given to speed up the powers of healing and hasten recovery.

Skin grafts are done frequently when indicated. The burns are grafted early if the surfaces are clean and suitable for a graft.

Summary and Conclusions

1. The morbidity and mortality of burns are definitely determined by: (1) the absorption of a toxin or toxic substance from the site of the burn; (2) the loss of body fluids; (3) infection; or (4) by a combination of these factors.
2. The initial shock must be treated by proper methods as soon as a burn patient is seen. This is as important as the local treatment of the burn.
3. Blood transfusion is of great value in severe burns.
4. We believe that the Bettman tannic acid-silver nitrate treatment is the treatment of choice in severe burns not contaminated or infected, especially if the patient is seen in less than twelve hours after the burn occurred.
5. The aniline dye treatment has been quite successful in our hands where infection is imminent.
6. In severely contaminated burns, moist saline dressings and cleansing with white soap is the treatment of choice.
7. Rigid asepsis must be maintained in the treatment of all burns.
8. If infection occurs, in spite of precautions, the patient is given daily sodium bicarbonate baths and moist saline dressings are applied.
9. Good nursing care is of the utmost importance.

CASE REPORT

SUPPURATIVE PAROTITIS AS A COMPLICATION OF MUMPS

EVERETT C. PERLMAN, M.D.
Minneapolis, Minnesota

IN MOST of the current textbooks of medicine, pediatrics or contagious diseases, little mention is made of suppuration in the parotid gland as a complication of acute epidemic parotitis. Differential diagnosis between the epidemic and the suppurative types is very definite and suggests to the reader that one never occurs with the other. Suppurative parotitis occurs, more than rarely, as a sequel to operative procedures, notably those for suppurative abdominal conditions, and also as a sequel to certain infectious diseases such as typhoid fever, scarlet fever, diphtheria, and pneumonia. Those following surgical procedures are attributed by Berndt[3] to general dehydration from vomiting, reflex diminution of the salivary secretion from the anesthetic and from surgical manipulation, as well as from actual trauma to the gland by unskilled anesthetists. Those occurring as complications of infectious diseases are due to a locus minoris resistantia rather than to a metastatic invasion of the gland, except in the case of typhoid fever, wherein the typhoid organism has been recovered from the infected glands. Various other factors in the incidence of this complication have been well reviewed by Lewis.[5]

That suppurative parotitis does occur as a complication of epidemic mumps, although rarely, seems evident in a few case reports scattered through the literature. It is therefore necessary to report this case, to the end that other similar cases may be recognized. In 1920 and 1921, Bernstein[4] saw three such cases in the School-Polyclinic, Odessa, all of which terminated by spontaneous rupture of the abscess into the external auditory canal. He thought that the tendency to abscess formation was enhanced by the marked exhaustion and the deficient oral hygiene of the children during the blockade and the typhus epidemic of those years. Alexander[1] also reported such a case in 1927 with a similar spontaneous rupture into the external auditory canal. Bader,[2] in 1931, reported a case of acute suppurative parotitis as a complication of mumps, with rupture into the canal, but this swelling was secondary to an otitis media of three weeks' duration.

Case Report

D. F., female, aged eleven, had a past history which was essentially negative with the exception of pertussis at six months and rubeola at four years. On February 26, 1938, the patient came into her home after play, with a swelling in the left parotid region, and announced to her mother that she had mumps. Several children, playmates, had had the same infection during the past few weeks. She complained of nothing else, and was not ill enough to be confined to bed. The swelling disappeared gradually during the next four days.

On the evening of the fourth day she complained of dizziness. She went to bed, slept all night and arose the next morning feeling well. In the afternoon she complained of pain in the right cheek. Her mother noticed that there was a swelling on this side of the face and that the child had a fever. That night she complained a great deal of pain in the ear and cheek and slept poorly. The next morning she was seen by a physician who told her that she had mumps. She was seen by the writer that evening and at that time she had a marked swelling over the right parotid gland with exquisite tenderness over the gland, under the jaw, and extending around to the right ear. There was no tenderness over the mastoid, but marked trismus was present. On slight pressure over the gland a thick yellow, purulent material escaped from Steno's duct. Her temperature at this time was 103.8 by mouth, and her pulse rate was 128. The right ear drum was not visible because of the swelling in the canal from pressure of the swollen gland. The orifice of Steno's duct on the left side also was swollen and surrounded by a red areola, but no pus was expressed. She was given supportive treatment at home and when seen, two days later, there was definite evidence of extensive suppuration in the gland, with an area of beginning fluctuation inferior to the helix of the right ear. Purulent material continued to exude from Steno's duct during all of this time. The next morning there was a spontaneous rupture of the abscess into the anterior wall of the external auditory canal, with profuse discharge of purulent material from the ear canal. There was also, by this time, definite fluctuation of the abscess below the ear. The temperature, by mouth, varied each day from 101 to 102.5.

At this time the patient was transferred to a hospital where the fluctuant area was treated with very small hot packs for twenty-four hours in order to localize the suppuration, and then it was incised. The incision,

(Continued on page 670)

MEDICINE IN WASHINGTON AND CHISAGO COUNTIES

(Continued from August issue.)

Besides their practice, the physicians found plenty of other things to do. In 1880 Dr. A. J. Murdock was elected treasurer of the Union of the Towns of the St. Croix Valley, secretary of the Chisago County Bible Society, and (in December) president of the town council. Dr. Millard was Washington county physician; Drs. Weiseman, Hallberg and Olding sold liquor (unfortunately without licenses), which caused them to be arrested. Dr. Comfort was for many years editor of a *Thompsonian Medical Journal.* Where and when this journal was published is unknown. In 1881 the office of Washington county physician passed to Dr. Caine. Dr. T. C. Clark was Stillwater city physician, and Dr. Millard took a long and very interesting trip abroad. Dr. Hallberg was physician for the Scandinavian Relief Association, a position he held for several years. Dr. A. J. Murdock served on the Board of Education, and was second vice president of the State Medical Association. In 1882 Dr. Olding ran a mercantile business. Drs. Murdock, Fliesburg and McComb shared the position of Chisago county physician, while Dr. Pratt was made county physician of Washington county, despite much opposition from the local homeopaths. Upon his return from abroad in June, Millard was elected president of the State Medical Association. Clark served as deputy coroner. Edgerton ran an eye and ear infirmary; Gaskill owned and managed a drug store. Zuercher proved his versatility by winning a $100 prize with a poem he had written. In 1883 Caine was elected one of the censors at a homeopathic convention. Watier was one of the incorporators of "Le Canadian" publishing company of St. Paul. Murdock was again president of the council of Taylors Falls, Millard was a member of the first State Board of Medical Examiners, and Umland was appointed county commissioner in the place of McComb, who had left for Duluth.

In 1884 Umland was nominated for the state legislature and Caine was reappointed surgeon for the Milwaukee road. Pratt was second vice president of the State Medical Association, as well as prison physician and member of the state legislature. Jenner left in February for a year's study in the hospitals of Berlin and Paris, and Watier turned from his publishing business to the job of running a drug store. At least two of the physicians had very interesting hobbies: Hodgkinson collected old medical books and owned a large library, and Umland was a very talented musician. In 1885 Caine was a delegate to the national homeopathic convention, and secretary of the association of sergeants of the first regiment. Merrill became county physician; Gaskill moved to South Stillwater and opened a drug store there, while McGuire opened one at North Branch. Among the pastimes which the doctors enjoyed was hunting, especially Umland, who got the first and finest buck of the season. Cooley, who at this time lived in South Stillwater, amused himself by constructing a large astronomical telescope, seven feet long, with a five and a half inch lens. He also made magic lantern outfits which he sold for $150 each. Apparently some one of the physicians who was in Stillwater at this time was a pretty good story teller, for in the *Stillwater Messenger* of September 30, 1882, appeared the following hoax:

"A physician of this city, whose name we are not at liberty to divulge, was one of a party of four students in the medical college from which he graduated who had shoes made from the skin of human beings which they purchased of dealers for dissection. His pair were made from the skin of a young lady eighteen years of age, and lasted him a year. The leather took a handsome polish, was very soft, but did not keep out the weather. . . ."

An unusual event, which deserves to be mentioned here, was the reception at Stillwater tendered the delegates of the American Medical Association on June 9, 1882. The convention that year was at Saint Paul, but all the delegates were invited to spend the day at Stillwater, at the home of Hon. and Mrs. Sabin. The guests were variously estimated at from seven hundred to over a thousand; they filled sixteen coaches. Three steamers—the Jennie Hays, the G. M. Knapp and the Sam Atlee—had been chartered, and the guests were given an excursion on the river. They then returned to the Sabin residence, where a grand dinner awaited them. The grounds were beautifully illuminated with Japanese lanterns; incidentally, upon this occasion electric lights were first used in the valley. A ladies' committee of arrangements waited on the guests. After the feast Dr. Millard called the meeting to order and Judge Murdock made the address of welcome. The delegates stayed until a late hour before returning to Saint Paul, and all declared they had never had a finer time.

Probably under the impetus of this meeting, another local medical society was formed. It was better organized than the preceding ones, and its constitution and the minutes of its meetings have been preserved. The first meeting was held May 31, 1882; officers were elected, consisting of W. H. Pratt, president; Carli, vice president; T. C. Clark, secretary; W. Jenner, treasurer, and Carli delegate to the State Association. The constitution was signed by P. H. Millard, C. B. Marshall, W. C. Voigt, O. A. Watier, T. C. Clark, B. J. Merrill, E. R. Jellison, W. H. Pratt and D. W. Jenner. Drs. J. R. M. Gaskill, A. H. Steen and J. C. Rhodes were elected members. The name chosen was the Washington County Medical Society. The next meeting was held some time later, on January 19, 1884, and officers were again elected. This time Pratt was president, Merrill vice president, Clark secretary, and Voigt treasurer. Censors were appointed by the president, and motion was made and carried that Pratt act as a committee of one to see that the "State Medical Act be complied with in the county, and to enter any necessary complaints before the State Examining Board." From this time on, meetings were held irregularly until the summer of 1885. Several papers were read by the members, and discussions were held on various subjects. After this society became defunct, another was formed, the Stillwater Medical Society. There are no records of its membership or meetings, and apparently it was chiefly a social organization. After this, there were no other local societies until 1902, at which time the present Washington County Medical Society was formed. This society has functioned, with only a few brief periods of inactivity, until the present time.

By the middle of the eighties many of the early pioneers had left the valley or had died. Dr. A. J. Murdock had moved to Saint Paul following the death of his father, Dr. Thaddeus Murdock. Dr. Comfort died in 1881; little is recorded of his history, but he had lived and practiced in Wyoming, Chisago county, for over thirty years. In March, 1884, Dr. Olding, who had also lived in Chisago county for many years, was found dead one morning in his bed. Dr. E. D. Whiting, another of the pioneers, died in 1882, after suffering for six months from a softening of the brain, and in 1885 Dr. Otis Hoyt died at his home in Hudson. Hoyt and Carli had often joked about which would attend the other's funeral, and

the margin was not a very wide one, for a little over two years later Carli also died. At the time of his death he was the oldest inhabitant of the city. There remained of the early pioneers only Rhodes and Gaskill.

The places left by these men were filled by a large number of new arrivals. A great many physicians came during the last fifteen years of the century, most of whom stayed only a short time, though some are still practicing in the valley. In 1887, when another medical practice act was passed by the state legislature, affidavits were signed by Drs. Maisch, Cooney, and Coats, stating that they were practicing in Woodbury, Afton, and St. Paul Park, respectively. The same year a Dr. F. H. Mitchell practiced for a while in Stillwater and St. Paul Park. A Dr. Freligh settled at Stillwater and Dr. Thomas Zein at Rush City, both of whom remained several years. In 1888 there were no new arrivals, but in 1889 Dr. S. O. Francis moved to White Bear, Dr. Oscar F. Thomas to Lakeland, Dr. George A. Carpenter to Marine, and Drs. C. M. Lee and A. J. Howe (or Stowe) to somewhere in Chisago county. A Dr. E. Carleys practiced at South Stillwater, Dr. Philip Muller returned to practice for a while in Stillwater, and Dr. E. Y. Arnold settled at St. Croix Falls. Although he resided in Wisconsin, Dr. Arnold had many patients in Taylors Falls and its vicinity. Many of the physicians practiced on both sides of the river, in both states.

In 1890 the Official Register of Physicians listed the following other physicians in Washington county: George G. Barnett of Lakeland, H. L. Brynildson of Vasa, Arthur De Voe, Albert Fenner, C. E. Hoveland, Julia M. Jacobson, James G. McCoy, Mary Reis Melindy, Leonard F. Pitkin, James Sinclair, and Eindred Viks, all of Stillwater, and Andrew Soderlind of Marine Mills. Directories of that year added E. M. Lundholm, N. Amherst Nelson and Lemuel P. Wetherby of Stillwater, and C. R. Keyes, who was hospital steward at the state prison at this time. Besides these, four midwives offered their services to the Stillwater public: Ursula Bauman, Mrs. Henry Hagen, Annie Tobisch, and Mrs. Cornelia Tozendine.

In 1891 F. Van Waters practiced in Stillwater, W. O. Tessier at Franconia, J. G. Erickson at Marine, and W. S. Fullerton at Rush City in Chisago county. In 1892 a Dr. Wilbur was mentioned as having a patient in the Stillwater hospital. In 1893 Dr. F. H. Hall served as steward at the prison hospital until he was obliged to resign to care for his wife, who had contracted typhoid fever, and in June, 1894, has place was filled by Dr. E. Sidney Bōleyn, from Minneapolis. After holding this office for a year, Dr. Boleyn resigned also, but remained in Stillwater, where he is still practicing today. Several other newcomers also made their appearance in 1894: Drs. S. O. Watkins, E. P. Ryan and Joseph Legault of Stillwater, J. F. Gemmel of Rush City, and E. E. Krogstad (or Krogblod) of somewhere in Chisago county. In 1895 A. J. Teiten practiced at Harris, Daniel G. Beebe was steward at the prison hospital, and J. G. Erickson settled at Lindstrom—probably the same Dr. Erickson who had been at Marine a few years earlier. In 1896 four new physicians were reported to be practicing in the two counties: F. J. Bedard and E. A. Edholm of Stillwater, C. L. Clark of White Bear and R. W. Getty of North Branch. In 1897 G. N. Watier, F. G. Landeen, J. H. Haines and a Dr. Lenox moved to Stillwater. Dr. M. E. Withrow arrived to fill the again vacant post of prison hospital steward. In 1898 came Drs. J. W. Rulien, C. M. Anderson and E. S. Fowler, all of whom practiced in Chisago County for several years, and F. L. Puffer, who lived on Bird Island. There were no new arrivals in 1899, but in 1900 Drs. P. C. Bjorneby and A. Lyon settled somewhere in Chisago county, and Dr. E. A. Riley at Willow River.

These, then, were the physicians who practiced in the two counties up to 1900.

Probably there were others whose names are not recorded, and certainly many of those listed are forgotten, since most of them stayed only a year or so. However, each one must have added something to the welfare and the history of the county in which he lived.

In the last fifteen years of the century there were few epidemics or diseases of much historical interest. This was probably due to the activities of the boards of health, which worked under the guidance of Dr. Merrill and several other physicians. In Stillwater the first of a series of thorough sanitary inspections was begun in 1885, which must have been quite an undertaking. Dr. Merrill's description, in the board's report, is interesting. "A house to house inspection," he wrote, "was begun as early as the weather permitted, and continued two months. The citizens in general were helpful, though others were arrested and brought before the municipal court. Thousands of loads of garbage and contents of privy vaults were taken from every part of the city to the dumping grounds. The city never underwent such a general cleaning before. The death rate has gone down in a remarkable manner (only one death from acute disease among 16,000 people in the month of June) and the health of our community is second to no other city or section in the entire country."

However, the best of cleaning could not have remedied for long the condition of the town, for the report continues: "The city is practically without sewerage, except that which its hilly conformation provides. Instead of the constant and efficient drain of a sewer, the householder is obliged to resort to the sluggish and terribly inefficient soil about his dwelling for the deposit of his slops and their drainage. This absence of systematic drainage has greatly impeded the work of the Health Board. We need some method for the daily removal of garbage, kitchen refuse and night soil, especially in the hot months, to complete our system of keeping clean. We also need a permanent sanitary inspector."

It seems amazing that a city over forty years old and as large as Stillwater was at that time had gone without these things for so many years, but it must be remembered that it grew so quickly and spontaneously that it was a large city before anyone had time to plan such a thing as a sewerage system, and, of course, people became accustomed to the lack of one. At that time cleanliness and health were not as closely associated in the average mind as they are today. These conditions were all later remedied, and until then the annual clean-ups were well conducted.

In 1888 Rush City followed Stillwater's example by having a sanitary inspection and general clean-up. Dr. Zein, the health officer, reported in the "Public Health": "During the past year the board of health has found it necessary to urge a lot of cleaning up; citizens generally were very helpful but we need a lot of cleaning. There was slight cause to resort to legal means. . . . The past year has been an unusual one for sickness and death. Diphtheria is a constant dread and a persistent visitor, and in a very malignant form; it seems to defy all attempts of the board to stop it. It has, in the past year, visited twenty-one families in the valley, all of whom have been quarantined. There have been fifty-three cases and twenty deaths, ten male, ten female, the youngest three years seven months old, the eldest twenty-one years three months."

"The Board has spent four hundred dollars cleaning up the village of nuisances, sources of filth and causes of disease, in maintaining quarantine and furnishing nurses and disinfectants for the poor." He added that slaughter houses required much attention, and concluded that the village was, finally, in good sanitary condition.

Despite the improving conditions, disease was still prevalent. In 1885 epidemics of scarlatina were reported at South Stillwater and diphtheria at Franconia and Schafer. In 1887 more complete reports show that in Washington County there were six deaths from measles, five from scarlatina, fourteen from croup, nineteen from diphtheria, thirteen from typhoid, eighteen from diarrheal diseases of infancy, twenty-four from phthisis, five from bronchitis and twenty from pneumonia. Chisago county, that same year, had one death from measles, eighteen from diphtheria, five from typhoid, twelve from diarrheal diseases of infancy, twelve from phthisis, three from bronchitis and eight from pneumonia. In 1889 the only epidemic of interest in Chisago county was a mild outbreak of scarlet fever at Taylors Falls. In Washington county the health officer reported that the city had an unusually healthy year; the drinking water was good, the city was kept cleaner than ever before, and the citizens were "becoming habituated to the notion of cleaning up at least once a year." Possibly the citizens were a little too satisfied with their work, for in July a sanitary conference which had been planned nearly fell through because of public apathy and lack of interest; only the exertions of the clergy and the vigorous comments of the mayor finally made it a success. The report continues that a sewerage system had been started but should be extended, and some means of dealing with kitchen refuse was still needed. However, the quarantine system was well developed.

Another item of interest in 1890 was the discovery of a leper in Rush City. One had been found nine years before in Washington county by Dr. Caine, but this was the first to be reported in Chisago county. It was discovered by Consul Christenson and identified by Dr. Gronvald. Both of these patients were Scandinavians. In the last decade of the century there were no serious epidemics reported, nor any particularly interesting diseases in either county.

Even in the state prison conditions were much improved, though still rather far from a modern conception of perfection. Arrangements were made for clean water, meals were eaten outside of the cells, new cells were built to relieve crowding, zinc night-buckets replaced the old wooden ones, and a sewer was constructed. The prison hospital was enlarged, and the use of antiseptics was introduced, and a graduate physician employed as hospital steward. A laboratory with a microscope and other instruments necessary for physical and chemical analysis was instilled, and a medical library was begun. All prisoners were given a thorough physical examination upon entering, and contagious diseases were isolated. These reforms were not introduced until 1893. Tuberculous prisoners were put in a separate wing. All of these changes were brought in slowly over a period of many years after much urging by the prison physicians, wardens, and various boards. That the city and village lockups could use some similar reforms was shown by a report made in 1890 by the secretary of the State Board of Corrections and Charities. The secretary had sent out a questionnaire which asked, among other things, what sort of beds and bedding were provided, and how often this bedding was washed and the lockup scrubbed. Marine Mills and North Branch performed both duties twice a year, White Bear and Franconia when needed, and Rush City, Stillwater and Taylors Falls made no report. Two other towns in the state replied once in ten years and never.

Besides attending to their practice most of the physicians served the community in some official capacity. Drs. H. G. Murdock, Stowe, Krogstad, Gemmel, Teitin, Rulien, Anderson, Fowler, Werner, Erickson, Zein, Bjorneby, Lyon and Robb all served as Chisago county physician at one time or another, while Dr. T. C. Clark held the same office in Washington county. Drs. Robb, Erickson and H. G.

Murdock served as coroners. Dr. Voight was city health inspector of Stillwater, and Drs. Cooley, Merrill, Fliesburg and Zein were health officers of South Stillwater, Stillwater, Fish Lake and Rush City, respectively. Dr. Merrill was also prison physician for a time, as was Dr. Pratt. Physicians who served as stewards in the prison hospital included Drs. Keyes, Hall, Boleyn, Beebe and Withrow. Dr. Keyes also made a study of cestodes, which was printed in the Transactions of the State Medical Association for 1890. Dr. George E. Clark was professor of homeopathy at the state university. Dr. T. C. Clark and Dr. Hallberg were both commissioners in the counties in which they lived. Dr. Marshall ran a drug store, and Dr. Watier manufactured a cough syrup. Several physicians travelled, Dr. Jellison going to China and Dr. Erickson to Sweden.

Dr. Beardsley was president of the village council of Rush City; Dr. Umland was appointed receiver of public monies at Taylors Falls, and later was postmaster at Fosston. Dr. H. G. Murdock was on the board of pension examiners, and at a meeting of the literary society he "entertained as soloist" though the nature of his solo was not described in the report of the meeting. The doctor was a "woodsman," and must have been quite a fisherman, too, for a news item in 1895 credits him with a morning's catch of two hundred trout. Dr. Caine, in 1894, had the honor of being mentioned as candidate for the office of Grand Exalted Ruler of the Elks, and the same year Dr. Mitchell, then of St. Paul Park, had the "honor" of a coat of red paint and feathers from the citizens of that town. Many of the physicians took an active part in the State Medical Association. Dr. McComb, then a resident of Duluth, was president in 1887, Drs. Rhodes and Stone served many years as censors, and Drs. Millard and Stone were delegates to the national convention. Dr. Merrill was essayist, his subject being "Medical Iconoclasm," and chairman of committees on finance, medical jurisprudence, legislation, and medical education. Dr. Pratt was also very active on many committees, and Dr. Millard's services are too well known to be repeated.

The last fifteen years of the century saw the passing of the last links with the early pioneer days: the deaths of Drs. Hoyt and Carli in 1885 and 1887, and Dr. Gustaf Colins, of Franconia, in 1889. Dr. Colins was over eighty years of age and according to his obituary had practiced for over forty years in the county, and was one of its oldest settlers. The obituary explains that he "had a natural gift for surgery, and was called the 'handy man' in that connection, being noted in his way for operations. He had no instruction, but always attended to dislocations and broken limbs without charge, even during his old age when he sometimes made mistakes." In 1891 the valley suffered the rather more serious loss of Dr. O. A. Watier of Stillwater. In April, 1894, Dr. J. R. M. Gaskill died at Danville, Ill., from the effects of poison administered in his coffee, evidently by accident. Several other persons in the same hotel were made very sick, but the doctor was the only one to die, probably due to the fact that, being fond of coffee, he drank more than the others, and also because he was in poor health at the time because of a recent operation. Three years later Dr. C. B. Marshall, who had practiced for many years in Stillwater, died following an operation for appendicitis, and in 1900 Dr. Umland also passed away, at Fosston, Minn. Umland had spent much of his time in the valley, though he had moved away some time before his death. One other event which should be mentioned was the passing of Dr. J. C. Rhodes. He was one of the earliest and the most prominent physicians in the valley, and the time of his death, in May, 1903, is an appropriate place to end this history of medicine in the St. Croix valley. The last of the pioneer physicians was gone, and the new century was on its way.

Group Hospital Association, Inc.

IF THE contemplated grand jury investigation of the District of Columbia Medical Society instigated by Assistant Attorney General Arnold materializes, the trial will hinge on whether the local medical society had grounds for expelling a member for accepting employment from the Group Health Association, Inc.

There should be no question of the right of a medical society to determine its own membership. From a practical standpoint, it is a simple matter for a society to decline election to membership. On the other hand, a physician already a member suffers injury by being expelled and generally cannot be expelled without cause. Was employment by the Group Health Association sufficient cause for expulsion from the District of Columbia Medical Society?

The Group Health Association filed articles of incorporation at Washington, February 24, 1937. It provided for medical and hospital care for any employe of the Federal government (the army and navy excepted) for $26.40 per year for a single person or $39.60 for a married person or one with dependents. Although really an insurance company, it was filed under the heading of benevolent, charitable, educational, literary, musical, scientific, religious and missionary organizations. The source of the capital necessary to launch the Association was, for a time, obscure. Eventually it became known that the Home Owners Loan Corporation had appropriated $40,000, which appropriation was approved by the Legislative Council of the Senate in February, 1938, and by the House Appropriations Committee, which, however, stated that it was the Committee's unanimous opinion that the expenditure was not authorized by law. The United States District Attorney for the District of Columbia has held that the Association is engaged unlawfully in the practice of medicine, and the insurance commissioner that it is unlawfully carrying on the business of insurance.

It would seem that the case for the District of Columbia Medical Society is rather strong.

The Group Hospital Association, Inc., threatens to entirely disrupt private practice in the District of Columbia. Incorporated to give medical and hospital care to Federal employees, who number about 840,000, and with their dependents some 2,500,000, irrespective of income, the effect on medical practice in Washington, D. C., particularly, is evident. So far its membership, we understand, has been limited to employes of the Home Owners Loan Corporation, a government agency.

Newspaper comment has been made to the effect that organized medicine has made a mistake in opposing a new method of meeting medical bills. Was the District of Columbia Medical Society to sit idly by and ignore an organization which threatened to annihilate private practice and which the society had good reason to believe would furnish inferior medical care to

its members? The Association had little experience whereby it could estimate membership fees and the medical staff required. The undertaking abolished any choice on the part of members as to medical adviser. Knowing the preference for doctors of their own choice manifest by most Americans, we wonder how the membership has reacted to the set-up.

Desirable as the equal distribution of the cost of sickness it, the Group Hospital Association, Inc., is a good example of just the form of group medicine which most doctors oppose. The Association has been backed by the Government, and presumably any deficits will be paid by taxpayers; free choice of medical advisers does not exist; membership is not restricted to the low income group, and in all probability the medical care offered will be of an inferior quality.

Has it come to the point where the Government can dictate the membership of a medical society when the activities of a member are disapproved by the society but approved by the Government? We think the Department of Justice has made a poor selection as a test case and that the Department has work cut out for it in the case of the Group Hospital Association, Inc.

Recommendations of the National Health Conference

THE National Health Conference, held in Washington in July, supposedly to discuss ways and means to meet the medical needs of the country, resulted in the recommendation by the technical committee of the Federal Government, that 850 million dollars be appropriated yearly for the next ten years, half by the Federal Government and half by the states, for what, in the opinion of the Committee, are much needed medical activities. These include an expansion of public health activities to the amount of 200 million yearly to combat tuberculosis, venereal disease, malaria, pneumonia, cancer and mental disease; 165 million for more maternal and child health service, to include the provision of medical and nursing care of mothers and newborn infants, medical care of children, services for crippled children, consultation services of specialists, and postgraduate training (for all income groups); 146 million for building more hospitals to provide 360,000 more hospital beds and 500 health and diagnostic centers; 400 million to provide medical care for the medically needy.

There is evidence in the proposed huge appropriation of nearly a billion dollars a year, half in the form of a Federal subsidy to the states, of entrance to a much greater degree by the Federal Government into activities heretofore conducted largely by the states themselves, and in addition provision for payment of medical bills for those considered medically needy and apparently in certain instances for those in the higher income brackets.

In considering the need for any such appropriation, it is interesting to note that, except for the years of the influenza epidemic, each year for the past twenty-five years has shown a reduction in the mortality rate of the country which has continued into 1938. Recent statistics published by the Metropolitan Life Insurance Company show that the death rate for the first six months of 1938 is much below that of any previous like period. Further, the recent survey of the Council on Medical Education and Hospitals of the American Medical Association shows that 98.5 per cent of our citizens live within thirty miles of a hospital. While there is doubtless need in certain areas for medical aid, no evidence has come to our attention of any general medical need not at present supplied.

Whether Congress will make this enormous appropriation is perhaps not problematic. Whether the states will appropriate dollar for dollar is, in the light of past experience, quite likely.

It should be remembered that this proposal comes at a time when some eleven million are unemployed, a situation which it is to be hoped and expected will not persist the next ten years.

Minnesota's need for the expenditure of several millions along the proposed lines is not apparent. There is no doubt but that the state would have to go further into debt to raise its share of the sum. It is to be hoped the state legislature will be able to resist the temptation to accept Federal subsidy for this great increase in government medical activity.

Aside from the question of whether Federal and State governments can afford such a great increase in appropriations of this sort, desirable

as they may be for certain scattered localities, the question resolves itself into what type of government we are developing in our country. What are the functions of the Federal government and what are distinctly those of the individual states? Is it the function of government to enter into competition with its citizens? Should private industry be called upon to make up deficits in government business activities? Do our citizens want government medical activities aside from those concerned with Public Health and medical care in general subject to politics? In short, do we want socialism?

The private practice of medicine is apparently about to receive another blow just as industry has received blow after blow from government intrusion. The wild appropriation of government funds, of which the proposal of the National Health Conference is another example, cannot go on indefinitely. It is to be hoped that our representatives will exert their prerogatives and call a halt before all government becomes bankrupt.

C. B. D.

Tact Toward the Sick

WHEN one is laid up at home or in the hospital and is bored with existence, nothing is more welcome or of greater aid in convalescence than the visits of friends. To feel that one has friends who are interested in one's recovery is an urge to get well. And yet there are friends who are totally lacking in what is called "tact," who cannot limit their calls but stay on and on; others who through the association of ideas relate similar or dissimilar cases of illness in which the outcome was not so favorable, leaving the patient exhausted and depressed.

The acutely ill need special consideration. While a friend can be a friend indeed in helping organize the medical care in an emergency, a seriously ill person has no energy to spend on visitors. The attending physician should lay down the rule "no visitors" and in certain instances even the nearest relatives should be limited as to duration and frequency of visits. The persistence with which some so-called friends insist on seeing an acutely ill friend, ferreting out the hospital room and showing a lack of consideration for hospital rules, is astounding. Even a telephone call was recently put through by an unwary hospital operator after bed-time, disturbing the patient's rest.

Sympathy is often due the wife of a man acutely ill in the hospital. Telephone calls keep her busier than a down-town central, and frequent and prolonged calls from solicitous friends only too often lead to exhaustion.

Even the attending physician deserves compassion at times when a patient with a large circle of friends happens to be acutely ill. During his moments of relaxation he is likely to be barraged with questions only serving to keep a subject already the source of much worry the more before his mind.

The obstetric patient should be mentioned. The long expected event has taken place and family and friends seem to think that mother and infant are eager to celebrate the occasion at once by holding a reception. Too often the inexperienced mother has this same attitude and the attending physician sometimes finds the recently delivered mother surrounded by relatives and friends who have long overstayed the proper time limit for such a visit, apparently awaiting the next nursing hour and a view of the newly arrived citizen-to-be. Nothing in hospital management has been harder to enforce than the exclusion of friends and relatives from the nursery of the hospital.

Then there is the hospital hound. A friend goes to the hospital and she (as is usually the case) trots down to the hospital and sits by the hour, often making several trips each day to keep posted on the progress of events. The more gruesome details she can learn the more a certain almost morbid pleasure is derived and the telephone wires are kept hot during spare moments with the latest bulletins.

There is one friend who should never be visited in the hospital. This is the type of neurotic woman who often with the connivance of a certain type of physician goes periodically to the hospital quite unnecessarily. With the room full of flowers and arrayed in her best and telephone at hand, she is prepared to greet the friends she has notified of her predicament.

After all, the matter of sick room visitors is of great importance to any patient and should receive the most thoughtful consideration on the part of the attending physician.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
W. F. Braasch, M.D., Chairman

SURVEY LAGS

Form No. 1 for physicians, most important source of information for the Survey of Needs and Supply of Medical Care, is coming in very slowly.

From the response to a recent inquiry, it appears that no county in the state has yet been able to report a 100 per cent return. Only a few are able to report 50 per cent or over.

Furthermore, the meager returns thus far submitted by the secretaries show that questions seven and nine, most important of all for the purposes of this study, have been too frequently omitted altogether.

Secretaries should canvas their members immediately to spur laggards and secure as complete a return as possible.

Organized medicine has cast doubt upon the reliability of statistical studies used to back up the government program for increased health protection, building of hospitals and possible grants in aid for establishment of state systems of health insurance.

This Survey is acutely needed NOW to provide facts and figures upon which physicians may rely and upon which sound programs of improvement can be built. They are equally needed to prevent the foisting of elaborate and expensive services unnecessarily upon the American people.

Medicine is being challenged daily in the magazines, on the radio, in the newspapers.

A complete and reliable presentation of the facts through the Survey is the answer to that challenge.

IMPRESSIONS GAINED FROM THE RECENT NATIONAL HEALTH CONFERENCE IN WASHINGTON

IN THE first place the gathering in Washington was no conference at all—at least in the generally accepted meaning of that term. As I understand it, the term conference implies an attempt to arrive at a solution of some problem by a group of individuals who might have different opinions but who possess authoritative information concerning the subject in hand. The problem should have free and frank discussion from all sides in order to obtain as much information as possible, and the only objective in mind should be to arrive at conclusions which would be mutually agreeable.

Cleverly Pre-arranged

Instead of a conference, a cleverly pre-arranged program was set up, with the sole objective of publicizing and supporting a program of health reform inspired by federal officials. Invited to the "conference" was a carefully selected group of some 150 individuals, most of whom were known because of their so-called liberal views toward medical care, and who had either written or spoken in behalf of these views. In the group were men and women with a wide assortment of occupations, including many social and welfare workers, magazine editors, newspaper men, and labor union representatives.

To give it an atmosphere of fairness, a small group of physicians representing the American Medical Association was invited. They were quite overwhelmed by the mass of hostile propaganda—and for all practical purposes, they might better have stayed at home. *Conspicuous by their absence were representatives of banking, investment activities, and of industry and manufacturing, who might have been interested in the financing of the vast expenditures involved.* Neither were there any economists or educators who had ever been guilty of entertaining any theories which might be called conservative or reactionary.

Discussions Released in Advance

Much of the time scheduled for the program of the conference was spent in reading the report and recommendations of the governmental health forces. These had been typed previously and had been read and studied by some of the delegates present. They also had been released by previous arrangement for national newspaper publicity from day to day. The discussion which followed was largely pre-arranged and the remarks made by many of those who took part in

the discussion were also previously written and dated for publication.

For the most part those who were called upon to discuss the problem were sympathetic with the government program and in most cases urged that even more radical steps be taken.

Emotional Well-wishing

It is difficult to understand the psychology of many of those who were assembled in the conference. One fact stands out above everything else, however, and that is that when it comes to opinions regarding the care of health, many intelligent people base their ideas more on emotion than logic. One wonders how intelligent men and women could make statements which were largely without factual basis and governed purely by emotional well-wishing.

It was surprising as well as discouraging to hear well-meaning representatives of such supposedly well informed organizations as the Farm Bureau Federation, Parent-Teachers Association, General Federation of Women's Clubs, and League of Women Voters get up and urge various phases of health socialization without acquainting themselves with all phases of the problems involved. It is to be hoped that these splendid organizations, usually well informed and unbiased, will in the future get their information on matters of health from all sources, including that storehouse of information available at the headquarters of the American Medical Association.

Lay Confusion

One feature of much of the laymen's barrage was a curious confusion of the indigent with the low income groups. Apparently many of the lay speakers failed to realize the fundamental differences in the problems involved in their health supervision. They did not seem to know that the health of the indigent was supposed to be under municipal, state, or federal control. It was rather ironical to hear their outspoken criticism of the failure of government agencies to look after this group properly when governmental control was supposed to be the objective of their arguments.

Doctor Ridiculed

The physicians present were placed in a curious position. One almost felt like a social outcast in the group, and a guilty conspirator to block justice and progress. We were placed in the role of selfish, narrow-minded individuals, having no vision or ability to sense reform and incapable of managing affairs of health as they should be managed. A jibe or sally at the unfortunate doctor was greeted with a round of laughter or applause. On the other hand, a calm statement showing what the physician or medical societies had already done and were trying to do to improve medical care received scant attention or was greeted with silence.

Sensational Publicity

Another feature of the conference was the sensational publicity of the proceedings by the daily press. Liberal space was given to the Federal Health program as released by the Interdepartmental Committee. Only the sensational features of the discussion were publicized, which were largely radical and in support of the proposed reforms. The remarks made by Dr. West and Dr. Abell, which stated that the medical profession was in sympathy with some features of the federal program, while others were regarded as objectionable, and their statements showing how much already had been accomplished by physicians along these lines, received only abbreviated notice in the press. The contribution of Dr. Cabot, in which he ridiculed the present methods of medical care, and the well merited rebuke by Dr. West, received more headlines than any other feature of the entire conference.

Unfortunately, the introductory remarks made by Dr. Cabot received but little notice but, in all fairness, should be repeated. Before reading his paper he spoke as follows: "I wish to have it distinctly understood that the views I hold in this controversy are my own and in no way represent the attitude of the Mayo Clinic." Instead of publicizing this statement, the newspapers gave the impression that Dr. Cabot spoke as a representative of the Clinic, which was quite contrary to the truth.

A Few Tricks of Their Own

It must be said that the skill with which the proponents of medical socialization have inoculated an increasing circle of the laity with their ideas is most impressive. They have learned all of the tricks practiced by other governmental activities marvelously well and added a few of their own. The way otherwise intelligent lay-

men mouthed the oft-repeated but incorrectly founded statements concerning lack of medical care is a startling illustration of what skillful propaganda can accomplish.

Purpose

The purpose of the conference was discussed in the introductory remarks of Miss Josephine Roche, the able General Chairman of the Interdepartmental Committee. The federal program for medical reform was discussed in general terms by its progenitor, Dr. Parran, Surgeon General of the United States Public Health Service. His sententious remark to the effect that medical care promises to be the main issue, both political and social, before the American people in the immediate future would seem to give clear warning of the purpose of the government to invade the promising field of medical care, both therapeutic and preventive, and use it for any political advantage that it may possess. The report of the Technical Committee and the agenda of the conference have been published in detail in recent issues of the *Journal of the American Medical Association.* A synopsis of the recommendations made, with a few random comments, may be of interest.

Program

The Technical Committee's study of health and medical services in the United States indicates that deficiencies in the present health services fall into four broad categories:

1. Preventive health services for the nation as a whole are grossly insufficient.
2. Hospital and other institutional facilities are inadequate in many communities, especially in rural areas, and financial support for hospital care and for professional services in hospitals is both insufficient and precarious, especially for services to people who cannot pay the costs of the care they need.
3. One-third of the population, including persons with or without income, is receiving inadequate or no medical service.
4. An even larger fraction of the population suffers from economic burdens created by illness.

The Committee submitted a program of five recommendations to meet these problems which are as follows:

I. Expansion of public health and maternal and child health services.

A. Expansion of general public health services. It is recommended that Federal participation in the program of preventive health service should be increased and, furthermore, that Federal participation be increased to promote a frontal attack, to (1) eradicate tuberculosis, venereal disease and malaria; (2) control mortality from pneumonia and cancer; and (3) promote mental and industrial hygiene.

B. Expansion of maternal and child health services. This includes provisions for medical and nursing care of mothers and newborn infants; medical care of children; services for crippled children; consultation services of specialists; and more adequate provision for postgraduate training of professional personnel. It includes, also, recommendations for the establishment of numerous health and diagnostic centers for these purposes. The total cost of taking care of the recommendations under A. is estimated at $200,000,000, and under B. $165,000,000, or a total of $365,000,000.

II. Expansion of Hospital Facilities. The Committee found hospital facilities inadequate and recommends a ten year program providing for expansion of the nation's hospital facilities by provision of 360,000 beds, and by construction of 500 health and diagnostic centers. Averaged over a ten year period the total cost of such a program was estimated at $146,000,000.

III. Medical Care for the Medically Needy. The Committee finds that, based on a National Health Survey, one-third of the population which is in the lower income levels is receiving inadequate general medical service. This applies to (1) persons without income supported by general relief; (2) those supported through old age assistance or work relief, and (3) families with small incomes. Current provisions to assist these people by any local and voluntary organizations and by physicians are not equal to meet the need. The Committee recommends that the Federal government, through grants-in-aid to the states, implement the provision of public medical care to these groups. It is estimated that on the average ten dollars per person annually would be required to meet the minimum needs for essential medical care, hospitalization, and emergency dentistry. This part of the program would probably reach an estimated level of $400,000,000 annually.

No statement was made as to how this money was to be spent, nor to whom it would go.

IV and V include a general program for medical care and insurance against loss of wages during sickness. The Committee states that without great increase in the total national expenditure the burden of sickness cost can be greatly reduced, through appropriate devices to distribute these costs among groups of people and over periods of time. The cost of the insurance and allied program has been estimated at approximately $2,600,000,000 annually.

To finance the program, two sources of funds could be drawn on: (a) general taxation or special tax assessment; (b) specific insurance contributions. The Committee recommends consideration of both methods.

Cost: 30 Billions

The role of the Federal Government would be principally that of giving financial and technical aid to the states in the development of procedures largely of their own choice. The maximum annual cost to Federal, State and local governments of all recommendations, other than the insurance features, is estimated at about $850,000,000. Over a period of ten years this would mean $8,500,000,000. **If compulsory health insurance is added to this at an estimated annual expenditure of $2,600,000,000, the ten year expenditure for this and the other program would amount to more than thirty billion dollars.**

The manner in which the inspired health reformers referred, without batting an eye, to the expenditure of billions was most impressive. If the government is actually called on to meet these demands, it will make the cost of old age and unemployment insurance look like a mere side issue. No doubt the alleged lack of business ability and financial sense in the medico accounts for his inability to disregard, in like manner, the stupendous sums involved.

Some Are of Value

Although it would be impossible to make a detailed review of these proposals in these columns, their comparative value may be summed up as follows: some of the recommendations are well founded and should prove to be of benefit to public health; others are either unnecessary or are not practical; and the rest would do more harm than good. Many features of those recommendations which are largely of a preventive nature will meet with approval by the medical profession, provided that the program can be carried out in close coöperation with and under the control of medical organizations.

Would Alter Medical Practice

Many of the recommendations which would alter if not transform the practice of medicine require careful study and investigation before they can be endorsed by the medical profession. Outstanding among these proposals may be mentioned the establishment of at least 500 health centers throughout the land for the control of tuberculosis, cancer and other lesions, and several thousand centers for the control of child health. These centers will, in order to be complete, necessarily require the services of a host of physicians in various capacities as specialists, technicians, and administrative officers, which, together with allied dental, nursing and technical services, will lead to complete modification of the present methods of medical practice.

It would be quite impossible for any nation-wide plan of this kind to escape eventual lay and political control, with leveling and deterioration of service, not to mention professional regimentation and suppression of individual professional initiative.

Based on WPA Figures

Most of the information and recommendations made in the Report of the Technical Committee and most of the statements made by the three introductory speakers on the program regarding the incidence of illness and lack of medical care were based on statistics obtained from the National Health Survey. This survey was made largely by WPA workers over a period of six months under the supervision of the Public Health Service. The resulting statistics are based on a house to house canvass of 740,000 urban and 36,000 rural families. Much of the reported illness and type of disease had no medical confirmation. The fact that the diagnosis and evaluation of reported disease was made without medical training would in itself make the survey of doubtful value.

A review of the survey reveals many other data which might be questionable. For example, statements made by persons on relief or with low incomes as to disease being the cause of their economic status may be biased. The frequency and severity of illness reported by this survey so greatly exceeds that reported by the Committee on Cost of Medical Care and that of the Metropolitan Life Insurance Company, and differs widely in so many other respects with these surveys, that the accuracy of the entire report is open to question.

Open to Question

Many broad conclusions were made from the survey statistics which are open to question, such as the statement that 40 per cent of the persons canvassed were receiving too low an income to maintain them in a healthy condition. This certainly is not true in most sections of the country—and even if it were true the problems involved are more economic than medical. The situation would be changed very little by

giving this group more medical care without correcting the economic factors.

The statistics purporting to show the percentage of individuals who receive no medical care are not even probable, furthermore. Most similar studies have shown that about 50 per cent of the population suffer no illness requiring medical care during any given year. The statistics in regard to relative need and distribution of hospitals in relation to the population have been proved to be quite erroneous by the careful survey carried out under the supervision of the Council on Medical Education and Hospitals. These are random examples but they show how statistics can be made to fit preconceived ideas and used to prove them.

Said Dr. Goldwater

Space will not permit a detailed review of the discussion which followed the reading of the various sections of the Committee Report. I have already indicated the general tenor of the remarks of those who took part. Among those few who discussed the problems from a more conservative angle was Dr. Goldwater of New York City and his remarks deserve special consideration. Unfortunately, space permits only a few quotations from his address, which are as follows:

"The objectives stated by spokesmen for the Interdepartmental Committee are commendable, but the program submitted arrives at its results by methods of calculation that are too simple to be reliable. Neglected illness is not always convertible by means of money grants or administrative measures into illness effectively prevented or cared for. A substantial fraction of increased government expenditure is almost certain to be used for more custodial care.

"Sincere enthusiasts who, thirty years ago, were sure that tuberculosis would be abolished by 1935, are still writing optimistic tuberculosis programs in glamorous terms of hundreds of fresh millions of dollars.

Self-help Preferable

"In health-protection, self-help is preferable to outside aid; government intervention in medicine is desirable as a last, not a first, resort.

"For similar reasons the efforts of county medical societies and of medical coöperatives sponsored by ethical physicians should be encouraged. These efforts are of primary importance in relation to home care, which is of concern to a greater number of individuals than actual or theoretically required institutional care.

"Medical care should be locally, rather than nationally, administered. The effective and economical administration of medical aid for the masses by huge Federal agencies is well nigh impossible."

The vigorous defense by Dr. Fishbein of the methods employed by the American Medical Association and organized medicine, ex-cathedra and also in the abbreviated time allotted him for discussion, should be mentioned. Also among those who contributed from the conservative side Dr. McCormack should be mentioned and Dr. Paullin, Father Schwitalla, Dr. Veeder, and Dr. Meyer.

In the summing up of the evidence for the plaintiffs by E. E. Witte, Professor of Economics, University of Wisconsin, the liberal cohorts were urged to press their cause even more than in the past. He pointed out that in order to obtain real progress action by the separate states would be necessary. He predicted that the honor of being the first state to support a health insurance law would probably go to New York, but that the immediate opportunities in Wisconsin appeared most promising. It would seem that our brethren in Wisconsin will be in for a hard winter and it is up to medical organizations in the surrounding states to give them all the support, both moral and actual, that we can muster.

W. F. Braasch, M.D.

FRONT PAGE ATTENTION

Reverberations from the National Health Conference had scarcely died down in the press when an investigation of the American Medical Association and its affiliate in Washington, D. C., the District of Columbia Medical Society, to determine whether or not their activities constituted a monopoly in restraint of fair competition under the anti-trust laws, claimed front page attention.

The investigation is the next step in the contest that has been going on for some time (résumé in these columns, May, 1938) between the District of Columbia Society and the Group Health Association of employees of the Federal Home Loan Corporation.

The Group Health Association was set up by a federal appropriation of $40,000 and is operated by monthly contributions of members with a hired medical staff. Both the original grant and the method of operation have been declared illegal and unconstitutional by various authorities and, on those grounds, physicians who associated themselves with it were threatened with expulsion from the society and were denied the

privilege of taking their Group Health Association patients into the hospitals.

Question at Issue

The District of Columbia Medical Society is not open to the charge of lagging in the provision of medical care to low income groups in Washington. Its bureau to assist in providing care for these people and in suiting fees to their ability to pay has been in successful operation for some time. The question at issue is whether or not the federal government may step in to finance a type of medical service which encroaches on the rights of physicians and holds grave possibilities for establishing a low standard of medical care in the District of Columbia.

To Be Tested in the Courts

According to a recent dispatch from Washington, three prominent Washington physicians have taken legal steps to bring the issue to a head and possibly force a Supreme Court decision on the legality of the whole matter. They have asked the district court to restrain the Group Health Association from practising medicine.

The likelihood that the federal charge of monopoly in violation of the anti-trust laws can be made to stick against the American Medical Association and its affiliate is extremely doubtful.

Physicians have nothing to fear from the law. Their problem is to prevent a swing of public opinion to a general unthinking endorsement without trial of compulsory health insurance.

PUBLIC ASSISTANCE

Figures for May, 1938, on case loads and payments to recipients of Public Assistance indicate a steady increase in the number of recipients and in the amount of money expended for it in Minnesota.

On December 31, 1937, the case load for Old Age Assistance in Minnesota was 62,357. On May 31, 1938, the case load had risen to 64,717. On December 31, 1937, the case load for children receiving Aid to Dependent Children was 11,512 in the state. In May, 1938, it was 14,688.

The same increase is apparent throughout the record. At the end of May there was an increase of almost 600 on WPA certification lists waiting for assignments, over the number on the waiting list at the end of April.

The *Monthly Review of Public Assistance* in the State of Minnesota issued by the State Board of Control provides complete graphs and tables showing case loads and amounts expended by counties for Old Age Assistance, Aid to Dependent Children, Aid to the Blind and certain limited data on WPA.

They should be of profound interest to physicians especially as a gauge of the welfare situation in Minnesota.

IF I HAD KNOWN

(Monthly Editorial Prepared by the Medical Advisory Committee)

If I had only known—. One of our members so expressed himself after a Summons and Complaint had been served on him recently in an alleged Malpractice suit.

If he had only known what? That many times your friends are the source of your most disagreeable lawsuit. You have confidentially told them of a case of yours. The news spreads. An unscrupulous lawyer hears of it. The patient is interviewed, and the story must be told in Court.

If he had only known what? That good records, not too meticulous, but covering the essential points from day to day, written, if possible, and, if dictated, read and signed by the attending physician on the case are a most necessary means of defense in Court. That these records are confidential, should never be altered, and are for the use of the doctor himself. They should be filed in such a way that only the Court can make them public property.

If he had only known what? That his fellow medical confrere down the street should be his most valued friend and that a good lawyer is a source of much peace of mind when a cloud of prejudice appears on the horizon.

If he had only known these things, your Medical Advisory Committee is sure he would have had less cause for worry.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Chiropractor Sentenced to Four Years in Prison

State of Minnesota vs. Herman V. Feenstra.

On August 10, 1938, Judge Joseph Moriarty of Shakopee sentenced Herman V. Feenstra, 65 years of age, an itinerant unlicensed chiropractor, to a four year prison term. Feenstra had been arrested at Lake Marion in McLeod County, Minnesota, on August 8, 1938, following an investigation by Mr. Brist on behalf of the Medical Board, Sheriff A. T. Beihoffer of Glencoe and Mr. Joseph P. O'Hara, county attorney of McLeod county. The investigation disclosed that Feenstra was doing criminal abortions and he was charged with one particular offense. His plea of guilty followed.

Feenstra stated he was born at Ackley, Iowa, and that he graduated from the Davenport School of Chiropractic in 1922. He located at Elkton, South Dakota but soon was in trouble there over abortions and lost his license. According to the clerk of court at Brookings, South Dakota, Feenstra has a conviction in that county for abortion and has been arrested for manslaughter, drunken driving and rape. The clerk stated Feenstra jumped a $2,500 cash bond January 19, 1938, at Brookings in the rape case.

Feenstra had two grips in his car containing instruments for doing abortions. He also had a supply of Leunbach's Paste (Merz & Co., Chemical Works, Newark, New Jersey). His records indicate that he has performed hundreds of these illegal operations, charging from $15 to $300 per patient. Many were done in South Dakota.

Feenstra was told by Judge Moriarty, "You are a menace to society and it is the hope of this Court that you serve every day of your sentence." Splendid coöperation was given by Sheriff Beihoffer and County Attorney O'Hara of Glencoe.

Quack Doctor Forfeits Bail Bond of $750 at Owatonna

State of Minnesota vs. J. A. White

On Wednesday, August 3, 1938, Judge F. A. Alexander of the Municipal Court at Owatonna ordered the bail bond of J. A. White forfeited because of White's failure to appear in court for a preliminary hearing following White's arrest for practicing healing without a basic science certificate. The defendant had posted the bond, signed by Ralph Brown and August Briese of Owatonna, on July 26th. Mr. Brown is a local agent for the Metropolitan Life Insurance Company and Mr. Briese is a farmer. The Court's order means that the bondsmen will have to pay Steele County $750.

White was arrested July 24 at Ladysmith, Wisconsin, following a joint investigation of his activities by Mr. Brist for the Minnesota State Board of Medical Examiners, Sheriff E. T. Helgeson of Steele county, and Mr. A. B. Anderson and Mr. Charles Stones, county attorney and assistant county attorney, respectively, of Steele county. White waived extradition and was returned to Owatonna, where he was released on the bond furnished by Mr. Brown and Mr. Briese.

White came to Steele county in the latter part of March, this year, driving a Packard car with Georgia license plates. Because of a bad snowstorm White asked for shelter at the home of farmers a few miles west of Owatonna. He represented himself as "Professor" White and also as "Dr." White; he claimed to be a psycho-analyst and in a few days was diagnosing ailments and suggesting pills, tablets, capsules, etc. He charged from $6.00 to $40.00 per patient. The medicine was purchased by White at drugstores in Owatonna for a mere fraction of the amount he charged.

Sheriff Helgeson sent White's fingerprints to the Federal Bureau of Investigation at Washington and was promptly advised that White was wanted at Jesup, Georgia, for swindling and practicing medicine without a license. White, in the meantime, had secured his release at Owatonna on bond and started for parts unknown. White also had been arrested in Detroit, Michigan, in 1918 on a charge of "larceny by trick." White claims to have been born in 1858 but appears to be sixty to sixty-five years of age; he is accompanied by Mrs. White. Judge Alexander issued a bench warrant for White's arrest and it is hoped that he will be apprehended somewhere.

The Medical Board wishes specifically to mention the splendid work done by Sheriff Helgeson and Mr. Anderson and his assistant, Mr. Stone; quackery cannot exist in a county where public officials give the whole-hearted coöperation and timely effort that was given in this case.

OF GENERAL INTEREST

Dr. E. I. Parson, who has just completed his internship at St. Luke's Hospital in Duluth, has located in Askov for the practice of medicine.

* * *

Dr. Dwight Martin, son of Dr. and Mrs. T. P. Martin of Arlington, was married recently to Miss Evelyn Kienitz of Saint Paul. Dr. and Mrs. Martin will make their home in Saint Paul.

* * *

Dr. George T. Ayres of Ely was elected president of the Vermilion Range Old Settlers' Association at the twenty-fourth annual reunion of the group, held at Eveleth in July.

* * *

Dr. Duane Olson of Gaylord was recently married to Miss Lyndis Iverslie of Delano. Dr. Olson is associated with his father, Dr. Duane O. C. Olson, in the practice of medicine at Gaylord.

* * *

Dr. W. G. Benjamin, of Pipestone, has recently been selected as a new member of the board of education at Pipestone. Dr. Benjamin is also president of the Pipestone Civic and Commerce Association.

* * *

Dr. C. E. Anderson, who has practiced medicine in Brainerd for the past thirteen years, has gone to Great Falls, Montana, where he will continue his medical practice. Dr. Anderson has disposed of his practice in Brainerd to Dr. W. E. Fitzsimmons of Saint Paul.

* * *

Dr. R. A. Glabe has become associated with Dr. J. A. Slocumb of Plainview for the practice of medicine. Dr. Glabe, who obtained his medical degree at the University of Minnesota, recently completed his internship at St. Luke's Hospital in Duluth.

* * *

Dr. Robert D. Mussey of Rochester is Vice Chairman of the Executive Committee and Chairman of the Educational and Scientific Exhibit Committee of the American Congress on Obstetrics and Gynecology, which is to be held in Cleveland, Ohio, in 1939.

* * *

Dr. T. J. Bloedel has become affiliated with the Bratrud Clinic at Thief River Falls, where his work will be limited to internal medicine, diagnosis and treatment. Dr. Bloedel graduated from the University of Minnesota, and served his internship at the Minneapolis General Hospital.

* * *

Dr. S. D. Wolstan has become associated with Dr. Oscar Daignault, of Benson, in the practice of medicine. Dr. Wolstan is a graduate of the Faculty of Medicine of the University of Paris. He served his internship at St. Louis Hospital in Paris and at the Swedish Hospital in Minneapolis.

MEDICAL BROADCAST FOR SEPTEMBER

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 9:45 o'clock every Saturday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

September 3—Premature Care
September 10—Birth Marks
September 17—Tularemia
September 24—School Dentistry.

INTERSTATE POSTGRADUATE MEDICAL ASSOCIATION

The International Assembly of the Interstate Postgraduate Medical Association of North America will be held in the Public Auditorium of Philadelphia, October 31, November 1, 2, 3 and 4, 1938. The Assembly will be preceded and followed by clinics in the various Philadelphia hospitals.

This well known medical meeting aims to present the newer developments in medicine and surgery with particular emphasis on their practical use from a clinical standpoint. The five-day program, which will occupy morning, afternoon and evening, except for Wednesday evening, which will be devoted to the annual banquet, will be presented, for the most part, by professors from medical schools of the United States and Canada. One European guest speaker appears on the program, Professor Dr. V. Eicken of the Medical Faculty of the University of Berlin, whose subject will be "Osteomyelitis of the Frontal Bone."

Philadelphia, with its wealth of clinical material, fine hospitals and excellent hotel accommodations, offers an ideal city for the Assembly meeting. The Philadelphia County Medical Society, the Pennsylvania State Medical Association, the College of Physicians of Philadelphia, and the Philadelphia Chamber of Commerce, will all coöperate to make the Assembly a success.

A cordial invitation is extended to all physicians in good standing in their state and provincial associations. Physicians are urged to bring their ladies, for whom an excellent program has been arranged. Philadelphia holds many places of historic interest which will make a visit to Philadelphia particularly attractive.

Attention is called to the list of distinguished Assembly speakers, which appears on page xxi of the advertising section of this issue.

Registration fee is $5.00.

This year's officers of the Association are: Dr. Elliott P. Joslin, President, Boston; Dr. George W. Crile, Chairman of Program Committee, Cleveland, and Dr. William B. Peck, Managing Director, Freeport, Illinois.

MEDICAL CORPS OF THE U. S. NAVY

Graduates of Class A medical schools between twenty-one and thirty-two years of age are eligible to take the examinations which will begin November 7, 1938. Applications should be filed at least one month prior to that date. Successful candidates will be commissioned as Assistant Surgeons with the rank of Lieutenant (junior grade) and assigned to the Naval Medical School, Washington, D. C., for a postgraduate course of instruction. Upon completion of the internship competitive examinations will be held for permanent appointment, the right to return to civilian practice being retained. The rank of Lieutenant affords compensation of $2,699 per year for those without dependents and $3,158 for those with dependents. Applicants must be American citizens.

For further information address the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

MILITARY TRAINING FOR MEDICAL RESERVISTS

The tenth annual training course for Medical Department Reservists (Inactive Status) of the Army and Navy will be held at the Mayo Foundation, Rochester, Minnesota, October 3-15, 1938.

Special clinical and hospital work will be given mornings and subjects in military medicine morning, afternoon and evening.

The program for the last three days will be merged with that of the Association of Military Surgeons of the United States. Surgeons General of the Army, the Navy and the Public Health Service will attend and participate.

All Medical Department Reservists are eligible for enrollment. Applications should be made to the Headquarters of the Seventh Corps Area, Omaha, Nebraska.

GRADUATE FORTNIGHT OF THE NEW YORK ACAMEDY OF MEDICINE

The eleventh annual Graduate Fortnight will be held this year from October 24 to November 4, 1938. The program consists of daily afternoon clinics at the various New York hospitals, evening lectures at the Academy headquarters, and scientific exhibits. The profession is invited and a registration fee of $3.00 admits bearer to all three groups of

meetings. For further details those interested should communicate with Dr. Mahlon Ashford, The New York Academy of Medicine, 2 East 103rd Street, New York City.

MISSISSIPPI VALLEY MEDICAL SOCIETY

The fourth annual meeting of the Society, which includes in its membership physicians of Illinois, Missouri and Iowa, will be held at Hannibal, Missouri, September 28 to 30, 1938.

The program will consist of over fifty lectures, clinics, short courses and round table discussions. An All-Chicago program will occupy the first day of the meeting with a Stag Buffet Supper in the evening. A banquet and entertainment will be held the second evening. Dr. I. C. Brill, Assistant Professor of Medicine at the University of Oregon Medical School, winner of the Prize Essay Contest, will read his winning essay on Failure of the Circulation; Types and Treatment.

Physicians are cordially invited to attend. Harold Swanberg, M.D., 209 W.C.U. Building, Quincy, Illinois, is secretary.

CENTER FOR CONTINUATION STUDY

The Center for Continuation Study announces a fall program of six postgraduate medical courses. The subjects are Proctology, September 19 to 24, Diseases of Genito-urinary Tract, September 19 to 24, Diseases of Infancy and Childhood, September 26 to October 1, General Medicine, October 10 to 15, Diseases of the Skin, October 31 to November 5, and Tuberculosis, November 14 to 19.

The tuition for each course will be $25.00. Registration may be made by sending in a registration fee of $3.00, which will apply on the tuition. The enrolment in the course in Proctology is closed.

Physicians will find it to their advantage to live at the Center for Continuation Study, where delightful accommodations will be found. Members of physicians' families may accompany them and stay at the Center for the same living rates.

Physicians planning on attending the home football games with the Universities of Washington, Nebraska, Michigan, and Iowa which will take place during the medical programs should make their ticket applications directly to the Football Ticket Office, 108 Cooke Hall, University of Minnesota, Minneapolis.

As in the past, the faculties will be recruited from the staff of the Medical School, Mayo Foundation, and members of the Minnesota State Medical Association. In addition, distinguished clinicians from other centers will lead discussions. Among others Dr. Curtice Rosser, Professor of Proctology, Baylor University, Dallas, Texas; Dr. Hobart A. Reimann, Magee Professor of Practice of Medicine and Clinical Medicine, Jefferson Medical College, Philadelphia, Pennsylvania; Dr. Lloyd G. Lewis, member of the Urology Staff of Johns Hopkins Hospital, will appear on the programs.

Physicians planning to attend should make their reservations early as enrolment in each course is limited.

CENTRAL ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

The annual meeting of the Central Association of Obstetricians and Gynecologists will take place in Minneapolis, October 6-7-8, Radisson Hotel. Dr. J. C. Litzenberg will be the honored speaker. All physicians are invited to attend as guests.

HOMECOMING CLINIC OF MEDICAL ALUMNI

The Minnesota Medical Alumni Association will hold its annual business meeting at a luncheon at the University Hospital on Friday, October 14. This is the day preceding the Homecoming game with Michigan. The president of the Association, Dr. Robert L. Wilder of Minneapolis, has appointed Dr. Harold G. Benjamin as chairman of the program committee for the clinical presentations at the hospital on Friday morning. The details of this program will be announced at a later date.

In Memoriam

W. P. Ross

1893-1938

DR. W. P. ROSS died suddenly of a heart condition in his home at Ottertail County Sanatorium, Battle Lake, Minnesota, on June 25, 1938.

Dr. Ross was a Canadian by birth, having been born in Woodstock, Ontario, 1893. He became a citizen of the United States in the summer of 1937. He moved with his parents to Saskatchewan when a boy and obtained his preliminary education in that province. His medical education was obtained in the Manitoba Medical College, Winnipeg, where he graduated in 1923. His internship was obtained in one of the hospitals of Winnipeg. He was in general practice at Brandon, Manitoba, several years, following which he served as one of the assistant physicians at Ninnette Sanatorium, Ninnette, Canada.

Dr. Ross came to Minnesota in December, 1929, as assistant physician at the Southwestern Minnesota Sanatorium, Worthington. He held the position until November, 1937, when he resigned to take over the duties of Superintendent and Medical Director of the Ottertail County Sanatorium, Battle Lake, Minnesota. This position he was holding at the time of his death.

He was faithful to his duties and held high the ideals of his profession. The past ten years of his life were devoted to tuberculosis work, a phase of medicine in which he was intensively interested and to which he contributed much of value. He was a member of the Minnesota Sanatorium Association and the Minnesota State Medical Association.

He was married to Rita Brooks of Winnipeg on August 11, 1926. She, together with two sons, William and James, survives him.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE VITAMINS AND THEIR CLINICAL APPLICATIONS. Prof. Dr. W. Stepp, Doz. Dr. Kühnau and Dr. H. S. Schroeder, University of Munich. Translated by Herman A. H. Bouman, M.D., Minneapolis. 173 pages. Price, cloth, $4.50. Milwaukee: Vitamin Products Co., 1938.

OUTLINE OF ROENTGEN DIAGNOSIS. Leo C. Rigler, B.S., M.B., M.D. Professor of Radiology, University of Minnesota, Minneapolis. 212 pages of text. 254 illustrations. Price, student's edition without illustrations, paper cover, $3.00; complete edition, cloth, $6.50. Philadelphia: J. B. Lippincott Co., 1938.

THE HORSE AND BUGGY DOCTOR. Arthur E. Hertzler, M.D., of Halstead, Kansas. 322 pages. Illus. Price, cloth, $2.75. New York: Harper & Bros., 1938.

THE TECHNIQUE OF CONTRACEPTION. Fourth Edition. Eric M. Matsner, M.D., 50 pages. Illus. New York: National Medical Council on Birth Control, 1938.

THE STORY OF LUCKY STRIKE. Roy C. Flannagan, Staff Commentator of the Richmond News Leader, Richmond, Va., 71 pages. Illus. 1938.

THE ROCKEFELLER FOUNDATION, ANNUAL REPORT 1937. 506 pages. Illus. Paper cover. New York: The Rockefeller Foundation, 1938.

CANCER—WITH SPECIAL REFERENCE TO CANCER OF THE BREAST. R. J. Behan, M.D., Dr. Med. (Berlin), F.A.C.S. Cofounder and formerly Director Cancer Department of the Pittsburgh Skin and Cancer Foundation, Pittsburgh. 844 pages. Illus. Price, cloth, $10.00. St. Louis: C. V. Mosby Co., 1938.

ZUR ENTDECKUNG DER INSULINSCHOCKTHERAPIE BEI AKUTEN GEISTESKRANKHEITEN, INSBESONDERE BEI DER SCHIZOPHRENIE. Dr. Julius Schuster, Gewesener I. Assistant der Pazmany Peter-Universitat Psychiatrisch Neurologischen Universitatsklinik in Budapest. 90 pages. Paper cover. Budapest: Druckerei der Pester Lloyd-Gesellschaft, 1938.

THE MANAGEMENT OF FRACTURES, DISLOCATIONS, AND SPRAINS. John Albert Key, B.S., M.D., and H. Earle Conwell, M.D., F.A.C.S. Second edition, 1246 pages, illustrated. St. Louis: C. B. Mosby Co., 1937.

This book is one of the best and most complete, as well as concise descriptions of the principles, general aspects, diagnosis and treatment of specific injuries of the skeletal system that one could desire.

The chapter dealing with general considerations of fracture equipment desirable for any general hospital treating fractures is excellent. The authors are to be commended upon their inclusion of a chapter relating to first aid in fracture and automobile injuries, and also for their clear discussion concerning workmen's compensation laws affecting fracture cases and medical-legal aspects of fracture cases.

Discussion concerning diagnosis and treatment of injuries to specific portions of the skeletal system are clear, concise and complete. Illustrations are profuse and adequate. The index is complete and well organized. The book is practical in its entirety, relatively devoid of extraneous material, and should be a very useful tool to the medical profession.

C. H. MEAD, M.D.

DISABILITY EVALUATION; PRINCIPLES OF TREATMENT OF COMPENSABLE INJURIES. Earl D. McBride, M.D. Octave of 623 pages, illustrated. Cloth $8.00. Philadelphia: J. B. Lippincott Company, 1936.

This book is valuable in pointing out the factors that should be considered before an estimate of disability in industrial cases is to be made. The author suggests what he terms a functional measuring rod, composed of one hundred units. On this rod he assigns values to the factor of function in the following way: delayed action—10%; awkwardness—20%; weakness—20%; insecurity—10%; diminished endurance—20%; lowered safety factor—10%, and averse influence of conspicuous impairment. He states that many examiners may not agree with him on the relative values of the factors concerned. His functional measuring rod suggests the consideration of factors of function often overlooked in making estimates.

The author presents a good synopsis of the Workmen's Compensation Laws in operation in the United States. The chapter on "Industrial Back" is very interesting and instructive.

R. M. BURNS, M.D.

SUPPURATIVE PAROTITIS AS A COMPLICATION OF MUMPS

(Continued from page 649)

two centimeters long, was made just through the skin, along the lines of the natural skin folds at the angle of the jaw. The underlying tissues were then separated by blunt dissection. About forty cubic centimeters of greenish-yellow pus was evacuated, which showed pure staphylococcus aureus on culture. Two days later there appeared below the incision, in the region of the submaxillary gland, another fluctuant area which was emptied by blunt dissection through the previous incision. After a convalescence, uneventful except for the profuse drainage, the patient was discharged in about ten days. When seen one month later there was complete closure of the operative wound, with a normally functioning parotid gland, and all the symptoms had disappeared, including the trismus.

Conclusion

An unusual case is presented of suppurative parotitis complicating epidemic mumps, with spontaneous discharge into the external auditory canal.

Volume 21 OCTOBER, 1938 No. 10

THE SOCIAL SIDE OF MEDICAL PROGRESS*

HOWARD W. HAGGARD

Director, Laboratory of Applied Physiology
Sheffield Scientific School, Yale University

New Haven, Connecticut

IN DISCUSSING the social side of medical progress, I shall deal not so much with factual matters as with interpretations. Interpretations are inevitably opinions. And you may not agree with my interpretations. My excuse for presenting them on this occasion is simply this: it is as well at times to draw back a little from the details of immediate and practical projects and in contemplation to view medical and social situations in broad perspective, to see trends, directions and dimensions. Such a procedure serves to bring these matters to the front so that for a few minutes we may think about them in a way that is essentially detailed and philosophical.

Viewed in this way the feature that shows as peculiar to the present period is the rapid shift and change of long established social institutions. As we watch these changes, the realization is forced upon us that the body of society is a delicately integrated entity just as is the body of man—so closely knit and interdependent in its parts that a change in any one must necessarily result in a change in all other parts, in a total readjustment.

Thus if medical discovery is made and applied to the saving of lives, there must follow a reorganization of society as a whole. The saving of life results in a change in the age structure of the population. The change in the age structure of the population upsets the balance of established institutions and necessitates social and economic readjustments.

The consequences of somewhat less than a hundred years of not too intensively applied preventive medicine—mostly an impersonal sort of medicine—have been the enormous diminution in the diseases and deaths of early life—the acute infectious diseases and infant mortality. As a result, the average length of human life has nearly doubled in this period. The age structure of the population has shifted and is still shifting. The facts and figures are familiar to you: In 1900 there was one person of sixty years of age or over in every twenty members of the population; in 1930 there was one in every twelve; and by 1960 there may be one in every six—one-sixth of the population sixty years of age or over. Here is the greatest change of its sort that has ever affected civilization. In the past there have been changes from war and pestilence but they have been from loss, not saving, of life. Here, growing from medical advancement, is a social and economic problem of vast magnitude in which the first efforts toward solution have taken the forms of social security legislation and old-age pensions; but these efforts do not touch upon the real problems of old age and retirement in an industrial civilization. They do not touch upon the consequences to medicine.

It is axiomatic in our field that as one disease diminishes, others rise to take its place. As the incidence of tuberculosis, typhoid, dysentery and smallpox go down, cancer and diseases of the circulatory system rise correspondingly. The change in the leading causes of death in the last thirty-eight years is commonplace knowledge.

*Banquet address at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1938.

So far the physician sees clearly; but sometimes I think he fails to see that medicine itself is one of the institutions affected by the changes that are brought about. Completing its circuitous course through the social structure, the change eventually comes back to medicine. A readjustment must be made there. Medicine does not stand alone; it is an integral part of society. It must either make the necessary adjustments to change or be swept aside. Readjustment—continual readjustment—of medicine is the inevitable consequence of medical progress.

Readjustment is disturbing. We tend to resist it; and resisting it we sometimes get out of step with progress and are left behind. Such resistance is futile; its consequences are destructive.

In the face of such change there appears one of the peculiarities of medicine: the failure to realize that it must change as society changes. It has been one of the most characteristic features of the physician of all ages—and the present is no exception—to hold in a certain arrogance the belief that the form of medicine, the principles of medicine and its practice, are vastly superior to those of all preceding ages; that they are the ultimate, beyond which there can be no constructive change.

In short, the progress of medicine has always showed this: Medical thought has crystallized on a line of endeavor. This line has been followed long after its usefulness has passed. Medicine has then, to the great cost of the doctor, been stopped and redirected to move in another line until that in turn has lost its usefulness—until the form of medicine was no longer suited to the time and was therefore discarded by the public. This same process occurs in government as well as medicine; a regimen goes along getting more and more out of step with social needs. Then there is a war, a revolution, and a new start is made. This process repeats itself over and over.

Now what I say tonight is essentially an indictment of the inertia of modern medicine. And in so doing I ask you to remember that inertia does not apply alone to things that are stationary; there can be inertia also of movement. Medicine and the physician, following a course that has been set, stay fast to the direction with fixed attention and dogged disregard of the fact that goals may shift, that situations may alter; that the direction of the movement may no longer lead to the desired goals. In the past this phenomenon has occurred time and time again and medicine has dwindled out to futility. The same situation is, I think, developing today. And medicine, for all the apparent progress of medical science, can dwindle out again to futility. The medicine of today may be vastly different from the medicine of the past but the fact remains that the social and sociological forces that guide it, operate upon it today just as they did in the past.

The great danger that I see to the practice of medicine today lies in the very thing that has given medicine its modern preëminence: and that is science. The physician has committed himself to science. He stands or falls with it. My indictment tonight is against this science—a science that has led the doctor to neglect the equally fundamental and non-scientific social aspects of medical practice—those things that we sometimes sum up as the art of medicine, a thing about which the younger generation of physicians knows so little. The doctor, in making a fetish of science, may find himself worshipping alone. He will unless his medical practices are changed continually to suit precisely the society in which he lives.

The doctor of America in the eighteenth and early nineteenth centuries was not a scientist. He was a public-spirited man whose medicine suited the times. He was a social leader, embodying the rare combination of medical practice and sociology. He was arrogant when he thought of the lack of knowledge of his predecessors—sometimes of his own contemporaries. But this temporal arrogance is always a characteristic of the doctor. We today look with pity, mingled with contempt, on the practices of Benjamin Rush. It was Rush, you will remember, who made that pathetic statement: "Medicine is my wife and science my mistress." It was Oliver Wendell Holmes, with the arrogance of the succeeding generation, who commented: "Medicine may be his wife and science his mistress, but it cannot be shown that this breach of the Seventh Commandment was of any advantage to the legitimate recipient of his affections." Yet, in spite of his lack of science, Rush as practitioner and medical leader has no equal today.

It is that very matter of science that occupies my attention tonight. The tenet of the young physician today is too apt to be the reverse of that of Rush. He could almost say: science is my wife and medicine my mistress.

The reason for the mode of thought that pervades medicine today is not hard to find. The acquisition of knowledge must of necessity come before application; it has the primary place both in time and importance. In the last hundred years, with the introduction of the exact sciences into medicine, medical research has yielded some of the most beneficial knowledge that the human race has ever acquired. Enthusiasm has grown high and a mode of thought crystallized. The science of medicine has been elevated; the practice of medicine—the art of medicine—which is not a science and probably never will be, has been subordinated.

The emphasis (or overemphasis) on research has resulted in the development of an aura of sanctity about research. The acquisition of knowledge has received and still receives a cultivated regard amounting almost to a veneration, and one out of all proportion to the regard given to the application of the results of research. We seem to look only to the future—to put the whole emphasis of our endeavors on finding the means for curtailing disease without putting into use, to the fullest extent, the measures we have for those who need them now. This mode of thought, scientific research—the search for novelty, the new—is inculcated in the medical student and hence in the physician; it has given a direction to medicine. And the movement has developed an inertia so that medicine cannot readily turn to new directions, although those directions are clearly indicated.

Medical science, gentlemen, is not medical practice. The great benefits from the application of preventive medicine that so dominate the public mind today are again not those of medical practice. These matters are science and being science they do not require the participation of the practitioner. Any aspect of medicine that has been reduced to an exact science needs merely medical technicians and not physicians for its accomplishment. Such is the case with much of sanitation. Such is the case also with many of our diagnostic tests. At one time it required the consummate skill of the physician to determine in some cases the presence of syphilis; now a far more accurate diagnosis is made by a technician in the laboratory. When—and if—medicine becomes an exact science we shall no longer need the practicing physician. Until it does become an exact science, then we not only need him, but we should grant him his due and proper importance.

The practicing physician is not a scientist. He is, if he really practices medicine, more, far more, than a scientist. He is an artist. He does not deal with the controlled and limited matters of the laboratory; he deals with human beings. So long as the human mind in its full ramifications remains beyond an evaluation with scientific precision, then the practice of medicine must remain an art. So long as medical practice involves the personal contact of physician and patient then it is the art of the physician which must establish the necessary bond. This is very different from medical research. It is, in many ways, more difficult. It involves not only intelligence and skill, but also qualities of personality unnecessary to the research worker. This personality element in medical practice has been—if not openly at least by indirection—scoffed at by the scientist or ignored.

There are two sides of medicine and we tend to confuse them. On one side is the medical research worker searching for knowledge; on the other is the practicing physician applying that knowledge. Far oftener than not the research worker is a poor physician. There is more to medical practice than the mere knowledge of medical fact. There is the old and true adage that "you can't carry an experiment bleeding from the laboratory to the bedside." The medical research worker and the practicing physician each has his proper and equally important place.

And yet with the emphasis placed upon science, with the public believing in the marvels of science, with the kudos of science, the physician has very naturally wished to believe that he was a scientist.

In the first flush of the triumphs of the application of science to medicine, it appeared that all the problems of medicine were to be answered and that medicine at last was destined to become as exact and impersonal as engineering. In consequence, to the eventual great detriment of the practice of medicine, our medical education was changed. It adopted the precise

methods of science. It built its structure on the laboratory as a foundation.

Trace with me the broad steps in the change in American medical education. A century and a quarter ago French medicine went through one of the periodic changes of direction—a drastic change in a revolution. The old staid and formal dogmatic teaching broke down to give way to an active clinical investigative type of medicine. In Germany the change came a little later but it was mainly German medicine that ours followed. A little over a century ago Germany, following the Napoleonic wars, was in the throes of a wave of idealism and romanticism that denied in the medical schools factual investigation and permitted only speculation. It was one of the extremes of the pendulum movement of education. Then it swung the other way; by the middle of the century German preclinical medicine had been founded by Johannes Müller. It was around him that the great school of Berlin was developed. His pupils, including Virchow, give the roster of the famous teachers and investigators of Germany. Almost without exception, and this includes Müller, they were men with enormous social interests. Virchow, you will remember, was as fearless and fiery in his political activities and his denouncements as he was in the classroom. The best of German medicine was gradually brought to America. The part that caught and held attention was the research aspect. At first the leading schools in this country were famous for their clinical teachers. The preëminence of Johns Hopkins in the closing years of the last century, and the early years of this century, was based on its great clinicians. Today, with the continual swing of the pendulum toward research, the preëminence of a school is judged, not by how well it trains doctors for the practice of medicine, but upon the eminence of its researches. The chairs once occupied by great clinicians with wide social interests and wide social influences are too often filled by scientists out of touch with the real problems of the practitioner. Few great scientists have been outstanding physicians. Harvey, who described the circulation of the blood, was a bad therapeutist; Koch, to whom we owe the conception of the bacterial cause of disease, gave up practice; and Pasteur was not even a physician. Formerly, students in our schools were trained to be socially beneficial. Now they are trained too often with the apparent intention of making laboratory investigators out of them and that in spite of the fact that medical practice is a social application. Today we train too often, not physicians with all the significance of the term, but instead, we train bedside pathologists.

Medical training is being divorced from medical practice; preclinical training is being sold out to educators who are not even physicians. There are those who wisely think that the student from the first to the last of his four years of training should be in contact with physicians and be taught clinically. Instead, there has grown up the whole division of subjects called preclinical. If they are preclinical they should be premedical. If they are taught in medical schools they should be taught, not as if in training for the Ph.D. degree, but instead constantly from the medical point of view and by physicians. Our grandfathers had only two years of medical training; it was almost entirely clinical; we are contemptuous of their deficient education. Today we have four years in our schools, but mostly we still have only two years of actual training in medical practice. The expansion has come from the addition of preclinical subjects taught in a detail and with a detachment wholly unnecessary to medical practice.

The emphasis upon science, upon the laboratory, has extended down even into the premedical field in the college. The selection there is made upon the basis, not of socially-minded individuals who would make good practitioners, but upon the basis of aptness in the laboratory subjects. The class of men who enter our medical schools, at least from our large Eastern colleges, are today, as potential material for social leadership, distinctly inferior to the young men from the same colleges entering law and business. We are turning away good men because no matter how great their ability might be as practitioners—they show no aptitude for the technic of medical research.

There is today a greater need for socially-minded, public-guiding physicians than at any previous period in medicine. The applications of sanitation are wiping out the infectious diseases of early life. In consequence, as I have mentioned, the average length of life has changed and with it the leading causes of mortality. The diseases that come to the front in

the modern medical readjustment cannot be cured or prevented by impersonal science. They can be controlled only by the close and intelligent coöperation of the individual members of the public with the physician. Obtaining this coöperation is a vastly different matter from acquiring the knowledge of how to prevent or treat the diseases. It is not medical research or science; it is the practice of medicine in its broadest service of a social leadership.

All achieved medical advancement consists of two distinct parts—and they are distinct. One is medical research in the acquisition of the knowledge of means by which suffering can be assuaged and diseases cured or prevented. That is the part today that receives the interest and the emphasis both in most of our schools and certainly in the minds of the public. But this part alone, this knowledge gained from research, accomplishes none of these things. They are accomplished and true advancement achieved only when the second necessary part is fulfilled. And the second part is putting the knowledge into application. Application is then for all practical purposes as important as discovery. Application belongs to the practice of medicine. Today unquestionably, with our enormous accumulated knowledge, there exists a wider gap between what can be done to control and prevent disease and what is being done than at any previous time in history. This fact is a grave indictment against the practice of medicine. It is the result of following a set direction of medical progress with no consideration of changing social conditions.

The great resultant danger to medical practice lies here. The public is beginning to realize the gap—the failure of application. The recognition will grow as long as these matters of application—crying in their need today—remain, if not in the contempt of the physician, at least not in his highest regard.

The social worker of today knows that the greatest, indeed probably the only possible field of social betterment, is offered by medical application. Some aggressive lay groups stand ready to raid the medical field for its unapplied potentialities. With the natural reaction of newcomers to the field—unacquainted with its ramifications, but sensing its deficiencies—they assume that there is something basically wrong with the form of medical practice. Their first inclination is to remake the form of medicine. Today the doctor must take his choice—lead or be led.

There is tremendous danger from this direction. Public opinion determines the condition and future of medicine. Today the public has an influence on social affairs and upon medical affairs greater than at any other time in history. But the actions of the public, unless guided, are always destructive, never constructive. People tend to pull down everything to the average level. Advancement, construction, is not made by great numbers, but by great individuals.

The only chance for medical leadership from the physician is to cultivate throughout our public a realization of what medicine can do; and to cultivate a coöperation between the public and the physician to do the things that medicine can do. In the last analysis it comes down to this: the shaping of public opinion to a high regard of medicine and of the practicing physician as its prophet. Unfortunately too much of the shaping has been to divert attention to the marvels of medical science and the deficiencies of medical practice.

It isn't what medicine does, it isn't what science discovers, that gives the necessary high public regard to the physician. It is what the public thinks and believes. And the public attitude reflects the doctor's own opinion of himself. If he thinks of himself as a scientist, he will be treated as one; he will be held in the same regard in which the physicist, the chemist, and the engineer are held. If he believes, as he should believe, and shows that he is a leader toward social betterment, worthy of public regard, he will receive that regard. These are matters of emotion and not of reason.

The physician, in casting his lot with scientific research, stands and falls with it. And he has chosen an uncertain support. We have grown to believe in the ruggedness, the permanence, the necessity of medical research. In so doing we delude ourselves. As a matter of fact, medical science is one of the most highly cultivated aspects of civilization. It can flourish, even exist, only under the most favorable conditions of civilization. A social disturbance destroys first of all medical science. It has happened in other countries and it can happen in our own just as easily. A little over a hundred years ago, as I said, there was no medical science in Germany.

The country was in the throes of a wave of romanticism and mysticism. Then in half a century Germany raised herself to world preëminence in medical science, set the course which we follow today. And then in the present century, under changing social conditions, medical science declined in Germany—it is disappearing; it has already gone in Russia, Italy and Spain. We still have it in our country. But it remains at the mercy of social change.

The permanent basis of medicine is not its research, but its social application—its practice. That has persisted in every age; it will endure in spite of our neglect of it. It can and will rise up to great importance if our public is taught to respect it.

In looking toward shaping public opinion we see today a situation such as has never existed before. We have a tremendous literate but uneducated public bound together by the marvels of modern communication—the radio and the printed page. The means for shaping public opinion exist as they have never existed before. The consequences are, at one and the same time, enormous dangers and enormous possibilities for doing good. The good or bad will depend upon the leadership and the ideas and ideals of the propagandists in medicine.

This field of propaganda is one in which I have been particularly interested for the last ten or twelve years. And here again as in the matters about which I have been talking I have definite ideas which are contrary to many of the present tendencies. These ideas are based on the belief that I have reiterated here, that the regard in which the physician is held is engendered in emotion—not in reason. The general tendency in medical propaganda by the physician and his organized groups is to tell of the glories of medical research—the new discoveries in medicine—to tell of medical knowledge. Years ago the physician carefully hid his knowledge from the public—made a mystery of his arcanas—wrote his prescriptions in Latin. He surrounded his calling with a glamor. Then there came a change, a reaction. The physician put aside the mystery. The measures of public sanitation could be put into effect only by the intelligent aid of the public, particularly in passing laws. He had no secrets left from the public—and he shouldn't have. But he went even further—he not only let the bars down, he let his hair down as well, and began in his new and rigorous scientific attitude to debunk the art of his own calling, to divest it of all its appealing emotional qualities. Instead of shaping public opinion he attempted to give the public medical information. Medical discoveries have become news, news about which lay writers express opinions, news which the public discusses from the factual point of view critically. It is a case of the dangers of a little knowledge. Far too often the propaganda lacks the one thing that propaganda should have and that is the cultivation of a public regard of the physician and of his calling—a regard that makes him something more than a scientist in search of novelty—that gives a veneration that the physician deserves and must have if he is to guide the American people.

My talk tonight is rambling in spots; it lacks the vigor and directness of the legal brief. It does so because these are things over which I am emotionally aroused. To my mind what I have been discussing is the decline of American medicine. On one side is research commanding public veneration; on the other is medical practice, a fair target, unprotected by public regard from the economic experimenter, the sociological reformer and the political opportunist. What I ask is not any decrease in medical research, indeed every increase, but that medical research and medical practice be recognized as distinct but equally important, equally skilled, equally valuable parts of medicine as a whole. I ask that we may recognize that a physician may be a great doctor without doing original and basic laboratory investigations; that such research belongs to the research investigator and practice to the practitioner. And most of all, I hope that we will go back to training our medical students clinically by great clinicians to be great clinicians.

MEDICINE AND THE LAW*

THE HONORABLE JOHN M. GALLAGHER
Chief Justice of the Supreme Court of Minnesota
Waseca, Minnesota

THE privilege of addressing this distinguished gathering is one that any citizen would welcome. It is one that any member of the bench or bar should appreciate. It affords the opportunity of exchanging views with the members of a great profession upon questions concerning which you, as members of the medical profession, and I, as a member of the legal profession, are similarly interested.

We speak of law and medicine as learned professions. We have learned lawyers and learned physicians of whom we are justly proud. Law and medicine are professions, which mean the common obligation of work to be done under the domination of the idea of excellence. The financial reward, if any, acceptable as it may be, is not the dominating idea. Law and medicine alike lure us on with those ideals of excellence, that we may well give them the best that any man can give.

Fate seems to have thrown the professions of law and medicine into fruitful contact, almost since their very beginning. The contact arises from the fact that both deal with the ills of human beings. And while the art of science of medicine is the older and has existed ever since organized society came into being, law, as a form of social control, has affected medicine.

In the modern legal world, the contact between law and medicine is greater, because of the limitations imposed by society, through law, upon the exercise of the profession, the manner of its exercise, and the use which law makes of medicine in the solution of some of its problems.

A trite definition of the physician or surgeon states "that he is one who is experienced in the art of healing or curing the disorders of the human body."

We need not discuss the historical development of the medical profession, or the constant broadening of social control over it. The profession itself has been chiefly instrumental in securing, in its own interest, and in that of humanity, the strictest regulations. It aims to weed out charlatanism and quackery. From the earliest times, courts have upheld the right of society, through its legislative bodies, to regulate the practice of medicine and surgery. These regulations have had as their chief aim the protection of public health—which is always a matter of social concern. The methods of achieving this, which courts have upheld, have dealt with educational requirements and standards, aiming to establish a minimum standard of skill and learning, as a prerequisite to the exercise of the science or art of healing.

The Court of this state, as early as 1889 (State vs. Fleischer, 41 Minn. 69), held constitutional an act passed by the 1887 Legislature regulating the practice of medicine, the licensing of physicians and surgeons and providing punishment for violations of the act. Holding the law constitutional Justice Collins speaking for the court said:

> "From the spirit and object of the act, plainly seen in its several sections, it is obvious that the lawmakers intended to establish a high standard of qualification and fitness for the medical profession, whereby the people might be protected from ignorance and quackery."

Later in State vs. Broden (181 Minn. 341, decided Oct. 10, 1930), the Supreme Court of this state held that the basic science act is not violative of any constitutional provision, either state or federal. Only recently in State v. Mielke, (277 N. W. 420, decided Feb. 4, 1938), the court sustained an information against a person who was endeavoring to circumvent the provisions of the basic science act by means of advertising and other quackery holding that the practice resorted to was a violation of the law.

Generally, the law has protected the public by holding the practitioner to a high degree of professional and ethical responsibility. This applies to the practice of medicine, or any of the other schools of healing, whose graduates are entitled to the license of physician and surgeon.

The law provides that the medical board may

*Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1938.

refuse to grant a license to or may revoke the license of any person guilty of "immoral, dishonorable, or unprofessional conduct" but subject to the right of the applicant to appeal to the court on questions of law and fact. The words "immoral, dishonorable, or unprofessional conduct" are defined in the act to mean:

(a) Procuring, aiding or abetting a criminal abortion,
(b) Advertising in any manner either in his own name or under the name of another person or concern, actual or pretended, professional superiority to or greater skill than that possessed by fellow physicians or surgeons . . . ,
(c) The obtaining of any fee or offering to accept a fee on the assurance or promise that a manifestly incurable disease can be or will be cured,
(d) Wilfully betraying a professional secret,
(e) Habitual indulgence in the use of drugs,
(f) Conviction for wilfully violating any narcotic law,
(g) Conviction of offense involving moral turpitude,
(h) Conviction of a felony.

It is evident, therefore, that while the standard of ethical conduct is high, it is not rigorous or unfair. Certainly no layman would want to trust a healer who did any of the acts denounced by the statute. It is also fair in allowing the courts to review the acts of the Board of Examiners, who, after a hearing, have deprived a physician of his right to practice. In reviewing the evidence presented before the board, the courts adopt the principle which applies to all bodies exercising quasi-judicial functions. Their findings will be upheld if there is any substantial evidence to support them. When there is conflict of evidence, the courts will not endeavor to resolve the conflict in a manner different from that of the Board.

When the law steps in to hold the physician accountable, in damages, for negligent acts in the exercise of his profession, it is also fair. It requires no impossibilities. It does not even require an abstract standard of skill. It requires a skill limited in time, and in character. Briefly stated, the fundamental principles governing liability for negligent acts on the part of the physician or surgeon are as follows: The physician is not a guarantor or insurer of cure. By accepting employment, he merely undertakes to use the average skill of other physicians in the same or similar localities. A mistaken diagnosis does not constitute malpractice, in the absence of negligence.

The following quotation from a case recently decided by the Supreme Court (Yates v. Gamble, 198 Minn. 7) is a good summary of the law on the subject:

"A physician and a surgeon is not an insurer of a cure or a good result of his treatment or operation. He is only required to possess the skill and learning possessed by the average member of his school of the profession in good standing in his locality, and to apply that skill and learning with due care."

This summary indicates that in modern times, the law takes a reasonable attitude towards the practitioner of the healing act. It does not punish him for failure to cure, in the absence of negligence. The law has not always been so charitable. The oldest code of the world, the Code of Hammurabi of Babylon (dating from 2250 B. C.) while doing nicely by the physician by regulating his fees, punished him severely for his failures. Here are some of the provisions of that famous code, taken from a new translation (J. M. Powis Smith: The Origin and History of Hebrew Law, pp. 211-212):

"215 If a physician makes a deep incision upon a man (*i.e.*, perform a maior operation) with his bronze lancet and save the man's life: or if he operate on the eye socket of a man with his bronze lancet and save that man's eye, he shall receive ten sheckles of silver.
"216 If it were a common man, he shall receive five sheckels.
"217 If it were a man's slave, the owner of the slave shall give two sheckels of silver to the physician.
"218 If a physician make a deep incision upon a man with his bronze lancet and cause the man's death, or operate on the eye socket of a man with his bronze lancet and destroy the man's eye, they shall cut off his hand.
"219 If a physician make a deep incision upon a slave of a common man with his bronze lancet and cause his death, he shall substitute a slave of equal value."

The physician is a valuable man to the court. This fact was recognized early in our jurisprudence. Physicians like to quote the following statement made by Mr. Justice Saunders in an English case in 1553, justifying the employment of a medical expert:

"If matters arise in our law which concern other sciences, we commonly apply for the aid of that science which is concerned therein, which is an hon-

orable and commendable thing in our law, for thereby it appears that we do not despise all other sciences than our own but we approve them and encourage them as things worthy of commendation."

Thus the help of the physician has always been welcome in courts. That prejudice has arisen against the testimony of the physician, when he appears as an expert, is common knowledge. I think the prejudice may be traced to the great divergence between the opinions of experts in mental diseases. They occur in important will cases, and in criminal cases—under the plea of insanity. The difficulty in criminal cases is often traceable to the difference between legal and medical concepts of insanity. In law, insanity implies inability to recognize the wrongfulness of an act. Our concept is based upon outmoded mental science or psychology. And when the physician and the lawyer speak of insanity they do not speak of the same thing. With the physician and psychologist, mental derangement may be entirely unconnected with any doctrine of responsibility. Moreover, according to the tenets of modern psychology, an ability to distinguish between the rightfulness and wrongfulness of an act, does not necessarily imply either wilfulness or responsibility. The psychopathic personality, which expresses itself in criminality, is the very embodiment of irresponsibility to the physician. And yet, in law, we hold him responsible.

I believe that in a great majority of cases difference of opinion between medical men arise for the same reason that differences arise between other experts. Lawyers are proverbially in disagreement, not only as to the meaning of decisions, and such differences are easily explainable when we consider how laws are enacted, enforced and interpreted. A legislature composed of two branches and consisting of men gathered from every nook and corner of the state assemble every two years for the purpose of enacting new laws, repealing old ones and amending others. It is not strange that errors and inconsistencies occur. The drafters have different political, economic and social views. Occasionally, a joker goes in. Is it a wonder that confusion and uncertainty exists? Is it a wonder that errors are made? To me the only wonder is that more errors are not made, that greater inconsistencies do not result.

Some of these laws eventually reach the courts for interpretation. The courts are as a rule made up of men of different political, economic and social views. They are even composed of a varied degree of ability and intelligence. It is only natural therefore, if they are honest, that they should sometimes disagree as to interpretation. And, fortunately, under our system of government each has a right to express his views as to such interpretation.

I hope that the time may come in this state when medical experts may become "arms of the court" rather than "aids to partisans." That is partially possible now under our compensation law. And still in such cases the expert must testify with full knowledge that his compensation must eventually come from the coffers of the employer.

Law both through legislation and court interpretation will continue to coöperate with the physician, as it has done in the past, to help him to carry on his noble calling. It will call upon him for aid when necessary and will aid him when occasion calls. Each profession needs the other. The public needs both. Each should, and, I am sure, will, in the future as in the past, aid the other.

PROFESSIONAL CO-OPERATION IN THE PUBLIC INTEREST*

STANLEY B. HOUCK†
Minneapolis, Minnesota

I HAVE been wondering why my talk to you has been placed between that of the Chief Justice of Minnesota and that of my very good friend, the president of your Association. I am not entirely clear whether I am intended to be the valley between the hills or the heights between the valleys.

I am especially pleased to be here this morning and to have an opportunity to speak to you. Before I say anything else I want to express the pleasure I have had during the past year, as a member of a committee of the Minnesota State Bar Association, in working with your Committee on Coöperation with the Bar, of which Dr. Branton of Willmar is chairman. These two committees of the Bar and of your Association have not only had a most delightful series of personal contacts and conferences but have laid the foundation and done much of the spade work for a more healthy relationship between the two associations and for a better regard by each profession for its obligation to the public and for the basic public interest. The work of these two committees is just begun. I do not know what you have done to continue your committee for another year. I hope you have made the necessary arrangements to do so.

I like to think of the medical and legal professions as representative of the highest possible type of professional existence. Each is, I am confident, freer from the taint of commercialism than any of the other so-called professions. In saying this I am not disparaging other professions, since they are usually by the very nature of things more intimately and inherently associated with commercial undertakings. The relationship of the medical and of the legal profession to the public is usually a more directly personal relationship than can be true of the other professions. This is true of the medical profession even more than it is of the legal profession. You deal only with persons and their ailments. The legal profession deals also with the problems and difficulties of natural persons but in addition deals with those of artificial persons such as partnerships, associations and corporations.

What the courts have said regarding the basic characteristics of the legal profession is likewise true in most respects of the medical profession.

The Supreme Court of Washington has said:

"The practice of the law is a personal right, and, that the public may not be imposed upon by the unworthy, the law requires that those engaged in practice shall be men of good moral character and with certain qualifications and a degree of learning to be ascertained by the agents, not of the courts, but of the whole people speaking through the legislative body. The right to practice law attaches to the individual and dies with him. It cannot be made the subject of business to be sheltered under the cloak of a corporation having marketable shares descendible under the laws of inheritance. One engaged in the practice of the law is subject to personal discipline for misconduct and to penalties for violating the ethics of the profession that could not possibly attach to a corporate body."

Justice Cardozo of the U. S. Supreme Court, when he was a member of the highest court of New York, said:

"Membership in the bar is a privilege burdened with conditions. The appellant was received into that ancient fellowship for something more than private gain. He became an officer of the court, and, like the court itself, an instrument or agency to advance the ends of justice. His coöperation with the court was due, whenever justice would be imperiled if coöperation was withheld."

From this, the conclusion is inescapable that our professional existence depends upon the public need. The license given us to practice our professions is not given to confer an advantage upon us as individual members thereof but to afford to the public whom we serve a necessary protection from exploitation and other abuses. The requirements of education and character are similarly imposed. They become more exacting as the public need for greater knowledge, greater training and greater skill develops.

I may summarize the fundamentals of our professions by saying that the prerequisites to a license to practice law or medicine are those

*Address given at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1938.

†Chairman of the Committee on Unauthorized Practices of the Law of the American Bar Association.

things which the public conceives to be necessary from time to time for its protection. The problem which confronts the members of each of our professions is how to so conduct ourselves in our professional relations that we shall supply what the public needs and demands without allowing such evils to arise as will cause the public to relax and liberalize its requirements preliminary and prerequisite to license to practice.

There is, of course, a distinction between the place of the legal profession and that of the medical profession in relation to the processes of government.

The principal, the effective distinction, between a lawyer and all others, whatever their walk in life, lies in the lawyer's relationship to the judicial department of our government and is largely a matter of his morals and character and his special education and training in the field of the law and his resulting knowledge of the rules of law, the principles of justice and the means and manner of their suitable administration. To round out the difference, the lawyer is an officer of the court and a direct agency and instrumentality—an integral part—of the judicial department. There is imposed upon the lawyer certain inescapable duties and obligations not placed upon anyone else, in respect of his every act and conduct, whether it affects himself, his client, the general public, or the court.

I pause, to digress momentarily. I hope you will not think, because of what I have just said, that each of you, as members of the medical profession, has no public duty to perform in respect of the administration of justice. The original basic obligation to do justice rests upon each of us without regard to the existence of courts or what it may be their province to do. It rests in the first instance upon each of you in the conduct of your profession and upon every other business and professional man. If all of us in our contacts and transactions with those with whom we deal did mere justice, as we are so obligated and in duty bound to do, there never would arise the occasion to apply to the courts for their aid to see that there is done the justice we have failed to do.

You are not a public agency, nor a part of any of the divisions or the departments of our local or national governments. You are not an instrumentality concerned with the administration of justice; nor licensed to practice law as an officer of any courts.

However, to an increasing degree, especially of late, members of the medical profession are coming more directly into contact with the processes of justice. The more intelligent administration of the criminal laws is making more frequent and continuing demands upon the medical profession for a saner determination and appraisal of the causes and degrees of criminal culpability and the suitability of the punishments and restraints about to be imposed or released. The astounding increase in personal injury litigation has made similar rapidly expanding demands in the field of civil litigation.

As the lawyer functions as a part of the judicial machine and as an aid to the court and to the public in the administration of justice, so does the doctor contribute to the doing of justice by the character of testimony and other forms of evidence he presents both before courts and before our administrative tribunals such as Workmen's Compensation Commissions.

As I have said, there is a basic duty on the part of each citizen to do justice. That duty, obviously, is not less in the case of members of either of our professions than in the case of the ordinary citizen. It can only be a greater obligation imposed because of our professional status. This imposes an added responsibility for seeing that the processes of justice, so far as we have anything to do with them, are not distorted, exploited or turned to the public injury or disadvantage.

Because members of the legal and medical professions are having more frequent dealings with each other in matters legal in character, the two professions inevitably must concern themselves more seriously with the problems arising therefrom.

The lawyer for the plaintiff and the lawyer for the defendant each turns to a doctor for testimony. With the plaintiff attempting to establish one state of facts and the defendant to prevent the establishment thereof, or to establish a different state of facts, a situation exists which provides fertile ground for serious abuses and presents problems calling for action not only by the individual members of the two professions but for the coöperative attention of both professional groups.

Probably the most common problem which

arises is the all too prevalent alliance between attorney and doctor. A continuing relationship —sometimes almost in the nature of a partnership or joint adventure—between lawyers who usually serve the plaintiff and a doctor who usually testifies on behalf of the plaintiff represented by the particular lawyer, cannot be viewed with equanimity by either profession. Nor, of course, is the relationship between the lawyer for the defendant and the doctor ordinarily and customarily appearing as a witness on behalf of the defendant in any better case. There are many abuses in this relationship. Certain attorneys almost invariably send all of their clients to certain doctors for treatment, for observation, all in anticipation of litigation and testimony. Attorneys for defendants do substantially the same thing.

It seems unnecessary to state that doctors employed under such circumstances are confronted with conditions not favorable to proper and ethical conduct either as doctors or as witnesses. If we add another factor and let the doctor's compensation be contingent or its amount depend upon the outcome of the case we have cause for the gravest concern.

Not only do lawyers send their clients to particular doctors but frequently the process is reversed and doctors urge their patients to go to particular lawyers for the purpose of collecting damages for physical injury. Sometimes doctors indicate that only thereby will they collect their bills.

In addition are the various forms of misconduct and abuse of the public of which individual members of each profession are guilty. Just as there are many lawyers who are known as "plaintiffs' lawyers" and "defendants' lawyers" so there are doctors who are generally known in the community as those from whom can be obtained testimony most appropriate to the plaintiff's case or most appropriate to the defendant's case. The eradication of such individuals from both professions is an obligation of each profession which calls for prompt action.

Nothing can be more serious in its effect upon the public than to have witnesses, and especially expert medical witnesses, participating in the "build-up" of a case, and interested in the amount recovered either because of participation in its planning or because their compensation depends upon a successful outcome.

The responsibility for such things can not be assigned alone to the individual. They can not be passed off by a shrug of the profession's shoulders and an attitude of indifference.

Both professions have imposed upon them the obligation to treat in confidence all communications from the patient or the client which are necessary to enable the member of the profession to deal with or treat the particular case. These are called, in the law, privileged communications. The reason for the obligation is known to all members of both professions. It is, of course, imposed solely in the public interest and to enable the better treatment of medical cases and the more certain assurance that justice will ultimately be done.

The development of medical science and the great changes which have occurred within recent years in the making of medical records and the use of hospitals as a part of medical treatment have resulted in substantial disregard of the patient's right to have his necessary communications kept scrupulously privileged.

There is the problem of the extent to which the privilege extends to hospital records. The position of the interne and the nurse in respect of these communications may be doubtful unless it can be said that they are at all times the representatives, the *alter ego,* of the doctor himself. Even then this does not cover all situations.

In the public interest the medical profession must concern itself at once with the protection of the privileged communications of patients. Doctors must themselves be more discreet and circumspect. They must either refrain entirely from communicating such disclosures to their representatives or must find some means of controlling these representatives so as to prevent disclosure thereof by them. Since hospital records are at least in an uncertain zone and are sometimes brought into court, practically as a public record, the profession must give consideration to the extent to which privileged matters may appropriately be entered upon those records. I have had clients tell me that because confidential and privileged matters communicated to doctors apparently become public property very speedily and very readily, they have felt compelled to go to a remote city for medical and surgical attention. Whether or not this be an exaggeration, it is not in the public interest that such a condition be allowed either to grow up to any extent or to continue.

Perhaps the most delicate of all of these subjects is the malpractice case. I have heard doctors say that at least 95 per cent of these cases are "frame-ups." I know very well the attitude of the members of the medical profession toward this type of action. I can sympathize wholeheartedly with that attitude. You need not tell me the reprehensible part that all too many lawyers have had in these cases. Here again is a problem concerning both professions. The legal profession must do what it can to prevent lawyers from seeking out, "building up," or exaggerating cases of this nature against doctors. But when a meritorious malpractice case exists, the plaintiff is entitled to the testimony necessary to the presentation of his case conformable to the processes of justice. The abuse which exists today may be more imaginary than real. I hope it is; but I am constrained to say that, rightly or wrongly, there prevails, both in the legal profession and in the minds of the public generally, the belief that one doctor will not testify in a malpractice case against another, regardless of the facts. If this be true, and I know it is true to some extent, there has been created a condition which the legal profession and the public must take prompt means to correct. However unjustly individual doctors may be treated when made defendants in malpractice cases, the answer is not a concerted effort on the part of the medical profession to suppress evidence and to interfere with and obstruct the administration of justice. Nor, in the public interest, can it be the province of a committee of the medical profession to review and pass upon such cases and determine whether they "should be settled" or tried. Together with the feeling to which I have already adverted, is the further belief that even in meritorious malpractice cases the medical profession has combined and conspired and united to force settlements on its own terms with the express or implied threat that unless such settlement is made no doctor will testify in favor of the injured person.

From what I have said it is apparent that there is much for each profession to do within its own ranks and much for both professions to do working together, coördinating their efforts and coöperating for the incidental benefit of each and both professions but with the primary objective of serving the public.

Abuses, such as I have referred to, do exist. They do not exist to anything like the extent believed by the public. The danger is not lessened in any way by the fact that the public believes it has been injured to a degree which has been greatly exaggerated. As I said at the outset, the excuse for our existence as professions is the public belief that it is necessary for us to exist in the manner in which we now exist in order that the public interest be thereby better served. Just as soon as we fail to accomplish the purpose and objective set for us by the public, or, what is more important, just as soon as the public thinks and believes either warrantably or not that either profession is not attaining the goal prescribed for it, there will be further attacks such as those to which each profession is now being subjected and these attacks, unless steps are taken to correct the public impression causing them, will result in measures which will seriously restrict and limit each profession.

I can not be too emphatic in saying that each profession must see to it that its individual members place the public welfare and the public interest above personal individual advantage and gain. I am not speaking idealistically. I am stating blunt facts. The public will not be idealistic about the matter. It will demand that the individuals making up each profession so conduct themselves as to serve the public interest and, if they do not, they will probably ruthlessly, recklessly, and perhaps unwisely, sweep the boards clear of everything characteristic of our present day professions and substitute something in their place which will not at all be to our liking.

HERMAN M. JOHNSON*

Past and Present Medical Problems

THE HONORABLE ELMER A. BENSON

Governor of the State of Minnesota

Saint Paul, Minnesota

Introduction

J. M. Hayes, M.D., President, Minnesota State Medical Association: Members of the State Medical Association, honored guests, ladies and gentlemen.

We are assembled here in this large dining room of the Hotel Duluth at the largest luncheon meeting in the history of the organization to do honor to the name of our departed friend and servant, Dr. Herman M. Johnson.

To me one of the most important duties of any organization is the commemoration of the names of those who were the most important factors in the success of that organization.

No man ever made greater personal sacrifices for any organization than did Doctor Johnson for this one.

Not only did he make great personal sacrifices, but no man ever had a keener, clearer and more plausible insight into future medical policy than did this same Doctor Johnson.

One of the most remarkable traits of this man in all his work was that no one could ever, justly, accuse him of promoting any selfish interests. Everything he did was in the interest of the public and the profession.

By doing honor to such a man we are doing honor to the association, and to the profession. Honoring such men should inspire younger men, at least to some degree, to attempt to follow in his footsteps.

Those who did not have the good fortune to be brought into close contact with Herman or closely associated with him in his work, will never realize or appreciate the value of his work to this association.

Fortunately, his Honor, the Governor, was a friend of Dr. Herman Johnson and quite closely associated with him in his work for many years. This association, I believe, has been a benefit to the medical profession. This association, I believe, at least to some degree, has taught the governor that the practice of medicine cannot, in justice to all, be made a political football. This profession knows no political bounds.

I am pleased to say that my experience has taught me that the Governor knows and recognizes the fact that the practice of medicine must be controlled and administered by the practicing physician.

It is my pleasure to present, now, his Honor, the Governor, who will give the first memorial lecture in honor of our departed friend and servant, Dr. Herman M. Johnson.

His Honor, the Governor of Minnesota.

*First address given under the Herman M. Johnson Lectureship at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1938.

Address

THIS gathering today is a memorial to the late Dr. Herman M. Johnson, of Dawson, Minnesota. Two years ago, his sudden and unexpected death brought forth, from people throughout our state and nation, expressions of regret at his passing and praise for his work and memory.

One of his life-long friends, former Governor and Congressman Theodore Christianson, paid him a personal tribute from which I quote the following:

"He was the very soul of honor. . . . He was direct, outspoken, sincere. If he ever lacked in tact, it was because he was so honest that he preferred to tell the truth even when it hurt, rather than to keep silent and have his own conscience accuse him of insincerity.

"He had keen perception, and an analytical mind. The ability to note symptoms and diagnose causes, to trace effects to their source, which made his professional career notable . . . he carried into fields outside that of medicine. Ofttimes I have been with him when, as with a surgeon's skill, he dissected the social body and probed for the causes of its ailments. When so engaged, he showed that mingling of courage and caution that characterizes the true scientist. . . ."

In this tribute by Theodore Christianson, I concur with all my heart; for, like many of you who are here today, I had the good fortune to know Doctor Johnson personally.

Soon after Doctor Johnson's death, the House of Delegates of the Minnesota State Medical Association, adopted a resolution declaring their grateful remembrance of his aid to their organization and their profession. "We can but hope," they said, "that the memory of him which is ours, and his spirit which abides, will carry us all on to higher and greater achievements."

In that spirit, his friends created a trust fund to perpetuate his work and memory. One means of doing so will be these annual Herman M. Johnson Memorial Lectures, of which my address today is the first.

I think it is extremely important to bear in mind that when we commemorate significant

work and noble men of the past, we do not have our eyes only upon the past; we have them also upon the present and the future.

A famous British scholar and scientist once pointed out that the present is, after all, merely the shifting point at which the past and future meet. We can have no quarrel with either the past or the future, he said. "There can be no world without traditions; neither can there be any life without movement. . . . There is never a moment when the new dawn is not breaking over the earth, and never a moment when the sunset ceases to die. It is well to greet serenely even the first glimmer of the dawn when we see it, not hastening towards it with undue speed, nor leaving the sunset without gratitude for the dying light that once was dawn."

In that spirit, we seek to perpetuate the memory and work of the late Dr. Herman M. Johnson. We do not want to forget his achievements; we want to look back upon them, and remember them with gratitude. At the same time, we do not wish to rest merely in the memory of such achievements; rather, we seek to take from them fresh inspiration to press forward to meet the challenging new problems of the future into which we are now entering. We seek to make the present not merely the twilight of a fortunate past, but also the dawn of a hopeful future.

Notable Achievements

In that spirit, we turn our eyes backward today for a few moments, to examine the notable and exceptional achievements of Dr. Herman Johnson.

Part of Doctor Johnson's distinction is the realism with which he adjusted himself to the special conditions of the period in which he lived.

He was born in the eighteen seventies. Up until then, changes in our economic and social conditions had taken place so slowly, that one could reasonably assume a man's children would live under conditions about like those under which he himself had lived. Since the eighteen seventies, however, owing largely to discovery and invention, change has taken place so rapidly that the very face of society has altered from one generation to the next.

Doctor Johnson began life in a pioneer community in Ottertail county, into which his parents had traveled in ox wagons from Wisconsin, about the time of the Civil War. As a child, he heard from the lips of his father many interesting stories of the first settlers in that region. When he himself began to practice medicine in western Minnesota, in the opening years of the twentieth century, rural calls were made with a horse and buggy. Between then, and the year when he died, nineteen thirty-five, there occurred sweeping changes in human knowledge, in the organization of human society, and in the problems confronting members of the medical profession.

Dr. Hugh Cabot, of the Mayo Clinic in Rochester, is authority for the statement that during the past forty years the development of scientific knowledge has given us more new knowledge, some of which is applicable to the treatment of disease, than the whole previous period of recorded history put together. The accumulation of scientific fact in that period, he declares, is so extensive as to stagger the imagination. As a result, during the past thirty-five or forty years, adjustments between professional activities, such as the practice of medicine, and current social and economic conditions have had to be made with a frequency and constancy which have challenged the caliber of men in the professions.

Doctor Johnson met that challenge. The record shows that he kept constantly abreast of the rapidly developing needs and opportunities of the medical profession during his lifetime.

Thus, one of the needs of Minnesota was a well organized and effective state-wide association of physicians and surgeons. Only by means of such an organization could the medical men of this state direct their influence fully toward developing programs of public health and promoting high professional standards in a highly complex society which was daily changing and becoming more complex.

Formerly, the Minnesota State Medical Association was only a loosely linked collection of county scientific societies. It exercised little influence in legislative councils. It assumed little responsibility for leadership in the protection of public health. Today, however, this association is generally spoken of by men in the medical profession as one of the best organized and most efficient medical societies in the United States. A great deal of the credit for this achievement belongs to the wisdom and ability

which Dr. Herman Johnson exercised in aiding that organization by his services, his contributions, and his counsel.

Outstanding Service

When the state medical association elected him president in nineteen twenty-six, they were indeed paying recognition to his medical scholarship and his skill as a physician and surgeon; but they were also honoring him for his faithful and important work, over a period of years, in behalf of the state medical association and the profession as a whole.

Doctor Johnson's outstanding service in that capacity was rendered as chairman of the Minnesota State Medical Association's committee on public policy and legislation.

In that position, he gave every effort to securing adequate appropriations for the equipment and maintenance of a first-class medical school at the University of Minnesota, which would meet the new needs for longer and more specialized training, and for wider and more extensive scientific research.

He gave every effort to securing adequate appropriations for our State Board of Health, whose record of achievement in public health programs is envied in many states of the union.

For the Public Welfare

He took part in achieving Minnesota's outstanding piece of medical legislation, namely, the Basic Science Law, enacted in nineteen twenty-seven, and generally regarded as a model of basic science legislation.

To Doctor Johnson, perhaps more than to any other person, should go credit for making the Minnesota State Board of Medical Examiners a self-supporting body.

Furthermore, he worked to have the Medical Act amended, so that when vacancies occurred on this Board, recommendations for filling them should be made to the governor by the Council of the Minnesota State Medical Association. He believed that recommendations made by organized medicine would be helpful to the governor in making these appointments. Here today, I have the privilege and honor of publicly acknowledging that we have kept faith with Doctor Johnson in this matter. The two most recent appointments to the State Board of Medical Examiners have been made in accordance with the recommendations of the Council of the State Medical Association, as he hoped they would be.

One of Doctor Johnson's most important and humane contributions to the people of this state was the coöperation he rendered, in nineteen thirty-four, when the state emergency relief administration was being set up. He spent many days conferring with relief administrators, and helping to organize the work, in an effort to insure that those who were unfortunate enough to be out of work and in need of relief would be able to secure the services of their own family physician when needed.

These achievements which I have been enumerating, are only a fragment of the long role of Doctor Johnson's public services.

They were prompted by his recognition of the fact that the medical profession, like all other human occupations, must constantly readjust its practices and organization to meet the intricate needs of today's complex conditions of life.

They were prompted by the social idealism which causes men like Doctor Johnson to labor wholeheartedly and with unfailing optimism for the achievement of the highest excellence in human skill, in human character, and in the organization of human activities.

They were prompted by the true spirit of liberalism, which, possessed of abundant and realistic knowledge of the facts and a sense of social perspective, seeks to find creative, rather than repressive, measures for liberating men from the diseases and scourges which afflict them.

How the work and memory of this man may best be perpetuated lies, after all, in the hands of the medical profession of this state. Speaking as a layman, I venture to suggest that the best way to do so is to apply his combination of social vision and a practical spirit to the facts and issues of the present.

From that point of view, let me try to outline for you what seems to me the next great field for organized medicine to tackle in the spirit of the late Dr. Herman Johnson.

Progress in Public Health

The province of caring for human health covers two fields. One field, the field of general medicine, is concerned with restoring sick persons to health. The other field, the field of preventive medicine, is concerned with maintaining healthy conditions of living in our highly

complex and artificial mode of living and working.

In this second field, the field of public health programs, the medical profession has been more than abreast of public demand. True, our programs of public health have not been entirely satisfactory; they have been marked by confusion, overlapping, and inadequacy—especially in the rural sections. This condition, however, is chiefly the result of inadequate legislation and lack of public understanding. Scientists and physicians have done their part in seeking to rouse people to the importance of adequate legislation and appropriations to carry on programs to protect the public's health by promoting sanitary living conditions, by checking the interstate transmission of disease, by preventing the pollution of public streams which flow from one community to another, by officially inspecting foods and drugs, by warding off occupational diseases and the effects of overwork in today's factories and mines, and by the collection of uniform vital statistics. In all these matters, medical knowledge has usually preceded that of the laity.

As a result, the field of preventive medicine and public health is beginning to be conquered. There already exist in the federal government, for example, at least two dozen agencies concerning themselves with the problems of public health, such as the United States Public Health Service, the Children's Bureau, the Women's Bureau, and the Bureau of Chemistry.

The Next Great Field

In the other and older field of medicine, however—in the field of general medicine, concerned with restoring sick persons to health, the medical profession is falling behind the public demands of the moment. As everybody knows, this is not because of any lack of scientific knowledge, skill, or devotion to the highest professional standards. It is owing to the fact that the present organization of our medical services does not provide for the widest possible application of those services to all our people.

In the year that Doctor Johnson died, in 1935, the President's Committee on Economic Security reported that "nearly one-half of the individuals in the lowest income group receive no professional medical or dental attention of any kind." The Committee also reported that millions of American families live in dread of sickness because when illness strikes one of their members they are compelled to sacrifice other essentials of decent living, or go without needed medical care, or depend upon the charity services of doctors and hospitals. Such a condition leaves large sections of our population without adequate medical service, and at the same time fails to provide adequate employment for large numbers of potential physicians and nurses.

Now, you and I both agree that it would be wrong to lay the blame for this state of affairs upon the medical profession. If blame belongs anywhere, it is upon the economic arrangements of our society. The important thing, however, is not to blame anybody, but rather to recognize that the problem exists, and then to seek methods of coping with it.

How will the problem be solved? I, as a layman, can scarcely venture an answer to such a question. The answer must come from the medical profession itself. *I may say, however, that I do not believe our people favor a government-dominated medicine.* On the one hand, they hold the medical profession in great esteem, owing to its traditions of learning, skill, and personal integrity; on the other hand, they lack faith in the arbitrary centralization of power which they fear would come from government-dominated medicine. Furthermore, the medical profession itself would not tolerate such an approach to the question.

Medicine's Problem

Nevertheless, we must recognize that the problem of providing all our people with some semblance of equality of opportunity for adequate medical service is one of the insistent problems of our time. This first memorial lecture, in commemoration of Dr. Herman Johnson, is the most fitting occasion possible on which to draw clear-cut attention to this problem, whose solution is the next step in the advance of organized medicine.

We laymen have confidence that the profession which produces and pays tribute to men of the caliber of Doctor Johnson, has also in its ranks the social vision combined with the practical capacity to grapple with this problem, and work out a solution which will neither mar the integrity of the profession itself, nor leave the medical needs of our population unmet.

Surely the time is not far distant when our people may expect government to aid them in

guaranteeing minimum standards of economic well-being, including medical attention of the kind they receive from the physician and surgeon whom they know and confide in. The people of this state would, I believe, be willing to consider favorably legislation designed toward this end, provided it came from the state medical association and represented their best judgment and matured experience. Such legislation would be one of the ways of keeping alive the memory and work of the late Dr. Herman Johnson. It would be evidence that his spirit abides, and is carrying us all on to higher and greater achievements. It would proclaim to all the world that we in Minnesota do not only rest in the twilight of a fortunate past, but also move forward serenely and without undue haste to greet the dawn of a more hopeful future.

FRACTURES—GENERAL PRINCIPLES*

CLARENCE JACOBSON, M.D.

Chisholm, Minnesota

THE treatment of fractures has its origin in the Neolithic age. Specimens have been discovered in sufficient quantities to justify statistical statements. Karl Jaeger found 53.8 per cent of good unions as against 46.2 per cent bad unions in prehistoric fractures, indeed a credit to Neolithic intelligence. Immobilization was practiced in the 4th Dynasty, about 2500 B. C. by means of well padded palm branch splints. Hippocrates, 460-377 B.C., describes mechanical extension for fractures of the thigh and leg. He advised treating fractures of the jaw by binding the teeth together with gold or linen thread. Fundamental principles adhered to by the ancients are still in use and to a great extent form the basis of modern treatment.

The first consideration in the treatment of fractures is to save the patient's life. Treatment begins the moment he is touched at the scene of accident and not after the arrival at the hospital. Preparatory to transportation, the patient is kept warm, morphine administered if necessary to control pain. The application of the Thomas Splint in fracture of the long bones is often a life saving measure and should be done before the patient is lifted from the ground. If possible, traction thus maintained should be fixed throughout the remainder of the treatment. This procedure combats shock, prevents further serious injury at the site of fracture, and adds materially to the comfort of the patient during transportation. Many hospitals make it compulsory to transport acute fractures of the long bones with some form of traction. The use of the Thomas Splint during the World War reduced the mortality from 80 per cent in 1916 to 15.6 per cent in 1917 in compound fractures of the femur alone.

Patients with fractures of the spine should be gently rolled on to a blanket face down and lifted by means of the blanket onto the stretcher, and kept lying on the abdomen during transportation. Cervicle spine fractures are best transported with some form of extension. In case of a suspected skull fracture the patient should receive no morphine and should be transported to the nearest hospital. If found in a home where favorable surroundings exist, transportation may well be postponed, a capable nurse secured to record the pulse, respiration, temperature and blood pressure. Emergency operative treatment in acute skull fractures should be limited to compound fractures, those showing marked depression of the skull, cases of extradural hemorrhage, and those exhibiting constant recurring convulsions.

Life is threatened in elderly patients who are suddenly compelled to lie in bed. Pneumonia and bed sores are often immediate complications. In the absence of shock it is imperative to free these people from pain and compel them to sit up. Recent fixation treatment with the Smith Peterson nail and other similar metal devices for fracture of the femoral neck have proven a boon to elderly people in whom these fractures so frequently occur.

Having assured ourselves that life is not in danger, our attention is centered on saving the injured part and to return in the shortest time the fullest capacity of function. Careful exam-

*Read before the Annual Meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1938.

ination of the injured limb is important, taking note of contusions and skin abrasions, injuries to tendons, muscles, nerves and vessels. Musculospiral paralysis is often missed in fractures of the humerus on first examination because of the attention being centered on the fracture. Amputation other than for the purpose of saving life should be based upon the extent of gross injury to the tissues and the question of adequate blood supply to the distal part. A more conscientious appraisal of these aspects has led to fewer amputations in late years.

Physiological principles are concerned with the healing of bone as well as the restoration of the injured limb to normal function. Immediately following a break, an orderly process of repair is begun. An interlacing mesh of fibrin derived from the blood clot, lymph and inflammatory exudate begins to bind the bone and adjacent lacerated tissues together. Within a few hours fibroblasts appear in the fibrin clot and granulation tissue formation begins. Cells from the endosteum, marrow, reticulum and periosteum enter into this formation as well. Organization takes place within forty-two to ninety-six hours. The manner in which calcium is deposited is not understood other than it makes its appearance as early as seventy-two hours after fracture, being deposited in the granulating tissue. This constitutes what is known as early callus formation. Denser deposits gradually appear, the concentration becoming sufficient to cause hard bone formation. Subsequent use of the limb causes the return of the normal architecture of the bone. A year or more is required to complete the process.

Interference with this normal process results in non-union. Among the common causes are poor apposition of fragments, early massage and passive motion, interposition of tissue even though it be periosteum, infection, extensive damage to soft parts at the site of the break, and, for purpose of emphasis, manipulation of the slow healing fracture. Failure to note callus formation on the x-ray plate lead many to unnecessary manipulation. It should be remembered that firm union often takes place without visible evidence of callus on the x-ray plate. Non-union can often be prognosticated on a history of violent injury such as having a limb caught in revolving machinery carrying the body with it, or in an auto accident where the car has turned several times with the occupant within. In these types the force producing the fracture has continued to act over a period of time. Cubbins states, "It is the continuation of force that has caused the interposition of tissue, that injures and destroys the periosteum, that causes its twisting and being torn to bits, as well as injury to the blood supply of the bones and adjacent tissues."

Principles governing the treatment of fractures are concerned with the best means of obtaining union in good functional position. Proper reduction is first to be desired. Perfect anatomical reduction should be attempted, but not at the expense of destroying possibilities of good function. Boehler, known for his exacting procedures, often allows up to one centimeter overlapping of fragments providing the alignment is correct. Actual lengthening of the lower limb has been noted by Magnusson and others after two years in femur fractures in children where no shortening was demonstrated at the time of discharge. The methods of reduction are many. Traction, manipulation and open operation are fundamentally the only three. Boehler states that every fracture should be reduced by traction and counter-traction. Manipulation, when used, should be reduced to the fewest number of movements and not over longer periods than absolutely necessary. Delayed healing and nonunion may be attributed to this procedure. There is much wasteful controversy over the merits of the open and the closed method of treating acute fractures. Whichever method gives the best results in function in the individual surgeon's experience should be used. All are agreed that there are certain fractures where open operation is necessary for maximum restoration of function. These compose the fractures involving joints where fragments are in poor apposition, some of the fractures of the mid forearm involving both bones, fractures of the patella and olecranon process, in fractures where there is known to be interposition of tissue between the fragments and in instances where fragments are widely separated. The optimum results are obtained in open reduction when the cases are selected and operated upon immediately. Henderson advises not to limit its use to cases in which the closed method has failed. Often in cases seen late where the closed method would have been satisfactory, he chooses to use the

open method. Skeletal traction by the use of Kirschner wire serves as an excellent method in obtaining proper reduction and in maintaining adequate retention. The Steinmann pin is likewise used. Some claim bone infection is more apt to take place when the latter is used. Boehler, however, blames infection upon the rotation of the pin within the bone, and has devised bearings on the tractors attached to the pin preventing it from rotating, and has had no further trouble. Maintaining reduction by means of a Steinmann pin incorporated within a cast as advocated by Roger Anderson has produced excellent results. Experience in this method and maintenance of aseptic surgical technic is imperative, not only in this method but in all methods involving entrance into bone with foreign material.

The means of retaining a properly reduced fracture is often the most difficult problem in fracture management. Fractures are maintained in their abnormal positions by muscle pull, gravity playing a part as well. When properly reduced anatomically and placed in a neutral position, the muscles of the limb resume a balanced pull and render a comparatively easy retention with the ends of the bones locked. Boehler has gone to great length in explaining the various neutral positions which must be maintained in proper retention. Thus, in fractures of the upper end of the humerus, the arm must be abducted 90 degrees, externally rotated 90 degrees and brought anteriorly 30 to 40 degrees. Correct alignment and anatomical apposition is thus attained. In fractures of the neck of the femur, we find that abduction with internal rotation produces the neutral position. In supracondylar fractures of the humerus, assuming the flexion and varus (adduction) position often interferes with the circulation and innervation to the forearm. Early recognition of vessel injury must be noted to prevent the dreaded Volkmann's ischemic paralysis. This was formerly thought to be due to tight dressings alone. We now know that blood from a severed or torn vessel has infiltrated the fascial planes which, not being elastic, causes enough tension to produce ischemia. The blood must be evacuated immediately. The radial pulse must return before the danger is passed. Boehler is not in accord with the usual practice of reducing and maintaining this fracture with the forearm in supination, for the simple reason that in so doing the pronator muscles, which are also flexors, being on the stretch, are in a state of spasm and tend to maintain adduction of the distal fragment causing impingement on the radial nerve. This is corrected by pronating the forearm, thereby bringing it into a relaxed position correcting the varus or adduction deformity. Being also flexors of the elbow joint, relaxation of the pronators brings about reduction of the flexion deformity. Retention is maintained by means of traction on an abduction splint in adults, either by plaster cast, aluminum or wire airoplane splints. The Jones sling and adhesive may suffice in children following satisfactory reduction. The same principle of neutral position with balance muscle pull holds for all fractures of long bones.

Operative retention by means of metal bone plates and screws may be necessary. The Lane technic must be strictly adhered to. Venable has shown that the metals commonly used are not suitable. When two different metals were used in plating a fracture, the difference in potential of these metals thus placed in the tissue acted like plates in a storage battery causing electrolysis to take place. Thus the screws were seen to loosen with consequent loss of retention. Certain alloys acted similarly. The best metal was found to be an alloy composed of cobalt, tungsten and chromium, called vitalium, which resists both electrolytic and chemical action of the body fluids.

Immobilization of the fracture is necessary until firm union takes place. This varies in individuals, and to a great extent in the type and location of the fracture. Firm union is best determined by the x-ray, although, as previously stated, union can take place without visible callus formation. The rule is, nevertheless, not to permit weight bearing or lifting without mature callus formation. Tenderness over the site of fracture means immature callus formation, and is, therefore, a warning to withhold use of the limb. Early removal of the cast for passive motion and massage is to be condemned. Non-union as well as myositis ossificans has resulted in these cases. Active motion is safer and is to be encouraged.

Restoration by functional treatment as advocated by Boehler is a distinct contribution to the industrial surgeon. He defines functional treatment as "the complete uninterrupted fixation of

the fragments in good position with the simultaneous active movements of all the joints, or as many as possible, and with the avoidance of pain." In short, this means immobilization with a cast placed upon the unshaven skin of an extremity and immediate use of the limb. A metal heel is incorporated in the cast in fractures of the lower extremities, and the patient made to walk as soon as the plaster-of-Paris is hardened. Circulation is thus made more active, atrophy of bone is avoided and the joints return to full function in a much shorter time. Fixation can thus be prolonged with safety. Compression fractures of dorsal and lumbar vertebræ are immediately reduced, guided by x-ray films and retained in a body cast, pressure being applied to three points, the upper portion of the sternum, pubic bone and at the site of fracture on the spine, thus maintaining the spine in lordosis. Patients without paralysis are encouraged to be up in twenty-four to thirty-six hours and are given weights to carry on their heads and such exercises as are necessary to keep up good muscle tone. Caution should be undoubtedly exercised in immediately adopting all these methods. We have had occasion to use this form of treatment in a sufficient number of cases to justify our continuing doing so. Experience gradually acquired will undoubtedly reveal the fact that the principle is physiologically sound, and that the future will see wider adoption of this method of treatment.

Needless to say, the keeping of accurate records and progress notes is as important in proper fracture management as in any other field in medicine. Many an unjust lawsuit has been won because of the poor record submitted at court. Litigation must be kept in mind in every fracture case. Failure to produce x-ray films before and after reduction has led to the same sad end. Plates taken in anterior, posterior and lateral planes suffice for the majority of cases. Plates at various angles may be necessary before ruling out fracture in instances where it is strongly suspected. Follow-up plates are necessary and should be taken every eight days until firm union takes place.

The general principles applicable to the proper management of fractures have been briefly alluded to. The best results will be obtained if whatever method is being employed proves to be physiologically sound. Perfect anatomical result should not be at the expense of optimum functional result. Most of the estimated 1,500,000 fractures occurring yearly in the United States are first seen by the practitioner and general surgeon. Smaller communities are being better equipped to care for these emergencies. We find that adequate consultation in complicated cases is of great value, not only for self protection, but for the welfare of the patient and his continued coöperation through a trying period of convalescence.

Summary

1. Some of the fundamental principles of present-day fracture treatment were used in ancient times.

2. The first consideration in dealing with fractures is the saving of life. Treatment begins when the patient is first seen at the place of accident. Proper first aid is of paramount importance as a life saving measure.

3. The use of the Thomas splint affords the necessary traction for fractures of the long bones and should be used in the transportation of patients with fractures of the long bones.

4. Interference with the normal process of healing by unnecessary manipulation and by early massage and passive motion is the cause of non-union. Cases of myositis ossificans have been reported by Boehler as a result of these measures.

5. Reduction is best produced by traction against counter-traction.

6. Retention in the neutral position of balanced muscle pull is necessary.

7. Longer periods of immobilization are to be desired for better bony union. Keeping the fracture immobilized and at the same time keeping the muscles and uninvolved joints active will prevent bone atrophy, and shorten the period of disability.

8. Adequate fracture and follow-up records, as well as proper x-ray plates during the healing period, are important aids to both patient and surgeon.

Discussion

Dr. E. E. Christensen, Winona: Dr. Jacobson has presented a very comprehensive review of the general principles of fractures.

His statements relative to the values of the open and closed method, I believe, are very fair. The open method should not be reserved for only those cases in which reduction has been impossible after repeated manipulations, but rather a method of choice when the surgeon recognizes the fact that he has to deal with a particularly difficult reduction and when the proper facilities are at hand. The failure to recognize these cases often leads to repeated manipulations and consequent permanent damage to the tissues.

Skeletal traction when properly applied has been of untold value in the treatment of fractures. However, these cases must of necessity be watched very closely and checked repeatedly by x-ray studies to avoid an over-correction or the pulling apart of the bony fragments with a resulting delayed or non-union. I believe this is more apt to be true when the Roger Anderson method of fixed skeletal traction is used in fractures of the neck of the femur, or in fractures of the long bones where there has been fixation by pins according to the method of Boehler. Of course in the hands of these men the results obtained encourage the contention that their methods are the ones of choice. However, the average practitioner, with a limitation of experience and perhaps limited facilities, should proceed, I believe, along more conservative lines.

I would like to bring to mind the so-called compensatory fracture, the majority of which occur in the leg due to the powerful action of the leg muscles. Here we encounter a fracture of the lower end of the tibia and our attention is centered on this one area. Unless we keep in mind the possibility of a fracture of the upper third of the fibula we may often overlook this point. The same holds true of the bones of the forearm but to a lesser degree, due to the free rotation of the latter. This type of fracture was brought to my mind very forcibly about four months ago when I completely missed the fractured upper fibula. It was only because of repeated complaints on the part of the patient that I had further x-ray studies made on the third day, and you can imagine my embarrassment when the second fracture was found. It is true that in most fractures of this type the end-result would not be appreciably, if at all, effected, if the second fracture were missed, but it is because of the medicolegal angle that we must keep this in mind.

My experience in immobilizing fractures with a cast directly upon the unshaven skin has not been satisfactory. I have noted a much greater tendency toward development of areas of pressure necrosis with this method than when using sufficient padding, particularly over the bony protuberances.

In the past four years we, in our group, have treated with very good results a series of thirty-nine compression fractures of the spine. Following reduction and the application of a cast, those in which there was no evidence of paralysis were allowed to be up as soon as they were free of pain and abdominal distention. This usually took between one and three weeks, depending upon the severity of the fracture. Most authorities are agreed that this type of fracture should be in a cast or brace and in the recumbent position for a period of from six to eight weeks. Dr. Jacobson has adopted the Boehler method, that of making this type of patient ambulatory in from twenty-four to thirty-six hours. This is even a greater departure from the time honored methods than what we have been using. If this treatment is correct, it will revolutionize the treatment of fractures of the spine in this country.

I thoroughly agree with Dr. Jacobson that follow-up records and frequent x-ray studies are necessary during convalescence for it is the one means that the surgeon has of knowing just what is going on. Failure to do this may result in a disability that affects the patient's earning capacity, which, in turn, assumes an economic and a medicolegal importance.

RECOGNITION AND TREATMENT OF REFRACTIVE ERRORS IN CHILDREN*

EDWARD JACKSON, M.D., Sc.D.
Denver, Colorado

ALL animals that move on the land, or in the sea, or air, have eyes to guide their movements. But these eyes differ greatly, to meet the special requirements of the animal. The eyes of a puppy are closed after birth; perhaps to keep him from running away from his source of food until he has learned to stay with it. The eyes of the colt are open from the start. With sight, his long legs can save him from wolves, or other enemies. The eyes of the infant open at once, to begin the long training in their use that they must have before they will be ready for the tasks of school and labor.

Human eyes differ from the eyes of the lower animals. Most lower animals need to see clearly at a distance, to keep away from their enemies, and to know where to seek their food. Men, too, need to see clearly at a distance; but they also need to see things held close to their eyes. They can see far away, but they also have a focussing muscle, that enables them to see small objects held very close to the eyes. Nearly all babies' eyes are hyperopic (far-sighted), and the average amount of hyperopia would unfit the eyes for use in school work.

Young children, with short arms, use their eyes for looking at small things held close to

*Read before the Annual Meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

their eyes. By this they get less and less far-sighted. At school age, six years, the average amount of hyperopia is not much over 2D.; and a few eyes have grown near-sighted. If the child strains its eyes, by holding things too close to them, they will become more and more near-sighted. They thus become subject to the dangers that may bring blindness from atrophy of the choroid, separation of the retina, or cataract. The wearing of glasses that enable the scholar to read print farther from the eyes, is the one important thing to prevent increase of myopia, and its consequences.

Astigmatism is a defect in the refraction of the eye, that prevents the light, which should be focussed to one point in the eye, from being so focussed. It causes the blurring of images formed on the retina, and causes straining of the eye to get the best image it can. It affects the seeing at all distances, and at all times. It usually continues throughout life but is liable to change from time to time. These anomalies or errors of refraction are so common and so serious in their effects during school life, that their early recognition and correction is very important.

Human vision is different from that of the lower animals. The human eye has the same powers of refracting light and forming images on the retina, the wide field of vision, and power of adaptation to light or darkness. But it also has greater power in detecting separate points of light, coming to it from different points of viewed objects that are close together. The cerebral coördinations of vision in man are far wider and more important than those of the lower mammals. The dog knows his master and recognizes other animals by his sense of smell. Man recognizes and discriminates by sight. His memories of persons and objects, animate and inanimate, are visual memories. In all our memories and coördinated thought, visual impressions predominate. Only what we learn by hearing may be compared with what we learn through vision.

The vision of the human eye is different because of the macula developed in the retina. The general retina is one of the first parts to become recognizable in the fetus, and it is well developed at birth. The macula cannot be recognized until the middle of fetal life, and continues to develop for months after birth. It may not reach its full functional capacity until the child is six or eight years old. Macular vision enables us to distinguish letters or small figures and to follow the mechanical trades that depend on "good vision." The education secured at school through use of books, exact drawing, fine needlework, and all the more accurate handicrafts, depend on macular vision. This is the kind of vision that makes possible human usefulness, successful living, and rational pleasure. Good macular vision is what is generally meant by "good vision." Our common tests of vision are tests of vision at the macula. Visual acuity is the visual acuity of the macula. In all normal eyes the visual acuteness rapidly decreases in the retinal field away from the macula. The vision, as usually tested and recorded, depends on the sensitiveness and accurate focussing of the light falling on the macula. This determines the effectiveness of the eyes in all kinds of school work. No scholar who has an uncorrected defect in vision should be expected to compete with others whose vision is perfect. Justice in the school room demands equal vision for the performance of visual tasks. So far as is possible, this should be brought about. Progress in learning is the purpose of schools, and it depends on seeing and hearing.

The school curriculum should provide first for the building of a strong, efficient body. The value and efficiency of our schools would be greatly increased, if the first two years of school life were devoted strictly to the building of bodily health. This could be effected by supervised playground exercises, directed to developing the power and control of the body. During this health education, the defects of sight could be detected, and refractive and motor defects of sight could be corrected before the most important employment of vision had to be entered upon.

How Are Refractive Errors Known?

Many children have been puzzled by defective vision, but have not understood what was the matter. Often, parents have thought that the child was simply inattentive, or stupid, or was not trying to see. But there is no excuse, except ignorance, or indifference, for not knowing how well, or how poorly, a child can see. Many charts have been devised for testing the vision of children and illiterates. The easiest and most efficient is the incomplete square, proposed by Snellen, when he found that his test letters were

not a good test for people who did not know their letters. Such a test may be turned in either of four directions, and the child asked or told to point in which direction the opening is turned. With this, a dozen children may be tested together, and in less time than for the same number of adults to be tested with letters. If a child does not have standard, or par, vision, some error of refraction should be thought of, as the most common cause of poor sight.

In the presence of refraction errors, perfect sight may be possible but more difficult. Children in this class are slower to see than those with good sight; or they do not like to study, seem in poor health, tire easily; or they have some nervous symptoms, as headache, restlessness, or nausea, or vomiting, when they use their eyes much for reading. These symptoms may come from other causes, but in school children who are having difficulty in keeping up with their classes, refractive errors should be first considered. The same troubles may be brought on by other things, such as poor light for reading, impaired health by loss of sleep, poor diet, lack of outdoor exercises, excessive home duties; or chronic disease, as malaria or tuberculosis. But the excessive demand of school studies with eye strain is obviously the first thing to be thought of by school authorities, parents, school physicians, or nurses, when they recognize any such departure from health in school children.

Defects of vision are so important to school children that their presence should not be left to accidental discovery. They should be kept in mind and looked for in every child coming under the care of school authorities. Parents do not expect such defects in their own children and have very little knowledge of how children with ordinary sight may be entirely unable to meet the requirements of school tasks. The playground supervisor and the grade teacher have ideal opportunities for observing such defects.

The indications of defective vision, such as holding the book too close to the eyes, or quickly getting tired of reading and letting the attention wander to more distant objects, may need to be explained to teachers and parents. This, the properly trained school nurse, or school physician, or the principal should be prepared to do. The assumption that the understanding of such things will come by nature is on a level with the explanation that reading and writing come by nature. Provision should be made to teach children what is good health and how to have it. This is the most important subject that can be taught in schools.

The campaign for health may well begin with the better lighting of homes and school rooms. Light, by contracting the pupil, is a universal corrective for all refractive errors. Try the small pupils for yourself. Take a +4. D. lens from the trial set, or grandmother's spectacles, too strong to see clearly with across the room. See how much blurring results. Then take the pinhole disk from the trial case, or a pin hole in any thin card, and hold it in contact with the glass, and look through the pin hole across the room. A few seconds will convince you of the effect of a contracted pupil in correcting the blurring due to refractive errors of the eye. The real need of corrective glasses can only be known by measuring the ocular refraction, knowing what the eyes are expected to do, and carefully considering the symptoms and the general strength and nutrition of the child. The absurdity of turning over health problems and health maintenance to the advertising claimants of skill in measuring eyes who in general call themselves "optometrists," may be easily appreciated.

There is a general feeling that this subject of optics is complex and beyond the average physician. In the cities, where certain young men are looking forward to making ophthalmology their life work, the proper examination of the eyes of all school children can be easily provided. In the country there are physicians in general practice who have time to read and study the methods of examining eyes for congenital defects including those of refraction. Any young physician might use his spare time in this way while waiting for a full practice, and thus improve his own fortune and render a very important service to his community. The practical points of visual optics are not so abstruse as might be supposed from looking over the classical books on the subject. And a training in medical diagnosis is the best preparation for the recognition and measurement of the refractive errors and motor anomalies of the eye. Experts in salesmanship, radio and newspaper advertisers, and the manufacturers of instruments and lenses, have profited by confusing the general public as to visual defects and their correction. Any well trained

physician may quickly train himself to give optical corrections to school children or patients.

For detection of optical defects in school children, a few schools have every child's eyes examined by a school physician. Others have the vision tested by a school nurse. This discloses myopia and high astigmatism. But other defects, such as high degrees of hyperopia, causing eyestrain, headaches, lack of attention and dislike of reading, can be only suspected by a teacher from daily observation. The essential point is that some one who knows of the existence of such defects, should be on the lookout for evidence of their presence. The presence of refractive errors, or their absence, may be determined in each child only on examination by an oculist.

Good lighting and correction of refractive errors supplement each other, but one is not a substitute for the other. In every school room will be found pupils who need correction of their refractive errors; and in most school rooms are children with desks poorly lighted. An exact light-meter, or sight-meter, should be used in every school room, to test the light available for use on the desk of each child.

The treatment of the refractive errors of the eyes of children is a most important, forward-looking step in preventive medicine—the medicine of the future. It is a great duty of parents to children, of one generation to the next. It is a duty of the State which demands the education of the young, to make them better citizens. It is the duty of the medical profession, to maintain and live up to its claim of leadership, in providing for the health of all the people. The service rendered to the child will last longer, and do more for the general welfare than anything that can be done for older people. All the knowledge and skill of the oculist of today should be applied in this developing branch of preventive medicine.

MEDICAL CARE

A wave of publicity regarding medical care is going over the entire country at the present time. Magazine articles, editorials and special syndicate articles are to be found in almost every periodical one picks up. We offer the following, reproduced with thanks by special permission of the *Minneapolis Journal* and United Features Syndicate, holders of the copyright, from the pen of the well known writer, Mr. Westbrook Pegler:

"The problem of medical and surgical treatment for the masses is cluttered with undeserved pity for people who have convinced themselves they can't pay the doctor for easing their pains or saving their lives, but could do so if they tried.

"The doctors of this country give away more free goods off their shelves than the members of any other profession, including actors and musicians, who come next.

"They have their gyps and rotters, their publicity-crazy hams and ignoramuses, but they do more good for suffering humanity and in critical moments than the members of any other calling.

"Of course, it will be argued that they should do this because they are in a position to. That is their job. But the fact is, nevertheless, that they do give this service, and it is a further fact that society doesn't appreciate the good they do.

"People overemphasize their mistakes of judgment or negligence, forgetting that a doctor's mistake is more likely to have fatal, or, anyway, dreadful consequences than a mistake by a plumber, a grocer, or a journalist.

"If the work of the plumber springs a leak, if the grocer sends Snookies instead of Snackies, or if the reporter names W. C. Smith as corespondent in the divorce story when it should have been W. G. Smith, that means very little paint off anyone's fenders.

"But, let a doctor make a comparable mistake and there is all hell to pay, on top of the fact that maybe he stood to be swindled out of his pay—or most of it, anyway—even if he had done a bang-up job.

"There are many phases of the question, but I mean to stick to this one for today's lesson. I am thinking of those who think that a couple of hundred dollars is an outrageous price to pay for the removal of an appendix which has developed the menacing nature of a bomb in the patient's inwards.

"The surgeon gets the victim into a hospital as quickly as possible, gives him a jab of something to relax him and in a very short time is delving around in his giblets without 50 cents on the line to pay for laundering his smock.

"So the patient gets well, and when the bad news comes he forgets that feeling as of a litter of porcupines frisking about in his abdomen, forgets how scared he was and his alarm for the security of his dependent family, and calls the doctor a burglar.

"Why, he makes only $25 a week, and so, instead of paying the doctor a dollar a week, as he would pay for a radio or sewing machine, his policy is to skip it entirely.

"He forgets also that if the surgeon hadn't done his stuff promptly and well, specialized stuff that nobody but a surgeon could have done, his family would be on the town right now.

* * *

"If a patient can pay small amounts to a coöperative over a spell of years for treatment which he may need in the future, he can just as well pay a doctor a stated amount each week over a long term for treatment which he has already received.

"But, in too many cases he just won't, and the doctor is accused of bearing down on a man who can't afford to pay for the saving of his life but can manage somehow to come up with the price of many non-essentials.

"Many doctors nowadays serve patients in the public clinics who are able to pay reasonable professional rates for their treatment.

"There is more or less larceny in all the human race and this problem of medicine for the masses would be less difficult if those who can pay were prevented from appealing to public sympathy at the doctor's expense by mingling with the truly destitute."—Copyright, 1938. Reprinted from *Bulletin of the Hennepin County Medical Society*, August 25, 1938.

CASE REPORT

TRIPLET PREGNANCIES—TWO CASE REPORTS*

MILTON ABRAMSON, M.D., Ph.D.

Minneapolis, Minnesota

TRIPLET pregnancies because of their rarity and because of the greater possibility of the development of complications for the mother should be regarded as definitely pathological.

Dr. J. C. Hirst in a recently published paper reports on a series of 48,357 viable pregnancies with delivery at the Philadelphia Lying-In Hospital, the University of Pennsylvania Hospital, and the Preston Retreat with an incidence of only four sets of triplets. Of these triplets, two sets survived. Complications present in one or more of these triplet pregnancies were unusual weight gain, hypertension, slow labor, "vague labor," puerperal endometritis, and abruptio placentæ between the second and third infants. The two cases I shall report are interesting in that both sets of triplets survived, both mothers exhibited hypertension and albuminuria (true toxemias of pregnancy), and in both cases the placenta separated between the births of the second and third babies, necessitating extraction of the third baby to save it from asphyxiation. Diagnosis of triplets was made in each case by x-ray study.

Case 1.—Mrs. M. R., a multipara, aged thirty-seven, gravida V, para IV, was seen at regular intervals during her pregnancy until December 7, 1929. At this time the patient was sent into the hospital for observation and study because of loss of 8.5 pounds in weight in one week, albuminuria 2 plus to 4 plus, excessive swelling of ankles, hypertension, and orthopnea of two weeks' duration. Patient's last menstrual period was on April 28, 1929, and her estimated date of confinement was February 5, 1930. The last menstrual period was slight in amount. Patient's past history was essentially negative. She had had four previous full term normal pregnancies and deliveries, labors averaging two hours or less.

General physical examination on admission to the hospital was essentially negative except for the fact that the patient appeared extremely emaciated, and that her blood pressure was 165/95. Blood pressure during her stay in the hospital varied between 192/106 during labor to 126/70 at the time of discharge. Eyeground examination was negative. Urine examination showed albumen varying from 0.4 to 3.5 grams per litre. Blood examination showed a hemoglobin of 77 per cent, 4,270,000 red cells, and 6,950 leukocytes. The Van Slyke estimation was 59 per cent. The blood urea was 7.7 milligrams, blood sugar .07, and creatinin 1.3 milligrams. X-ray taken on December 9, 1929 (Fig. 1) showed the presence of triplets with the head of one fetus in the fundus, the head of the second overlying the pelvic inlet, and the head of the third in the left upper quadrant. The size of the babies was approximately that of an eight months' gestation.

Labor began about 5 p. m. on December 25, 1929. Pains at first were quite weak but rapidly became stronger. Rectal examination at 5 p. m. showed a dilatation of 3 cm. and 50 per cent effacement with the head of the first fetus well below the spines. The membranes were intact and the fetal heart tones were good. The cervix dilated and effaced very rapidly with complete dilatation at about 6 p. m. The first baby was delivered in the OLA position at 6:40 p. m. Rectal examination after the birth of the first baby showed the second head presenting. The second baby was delivered in the OLA position at 7:07 p. m. There was an excessive amount of bleeding at this time and rectal examination revealed that the placenta had separated and was lying in the vaginal canal. A large bag of waters was present and the presenting part of third baby was not felt. A hand was inserted vaginally, the bag of water was ruptured, a foot of the third baby found, and the baby extracted in the SLA position at 7:12 p. m. Two placentæ were expressed immediately after the birth of the third baby. Birthweight of the babies were 2,100 grams, 1,650 grams, and 1,620 grams. They were all females. The mother made a normal uneventful afebrile convalescence. Blood pressure rapidly came down to normal, and the urine cleared of albumen. The patient weighed 112 pounds and was in good physical condition when discharged from the hospital.

Case 2.—Mrs. M. L., a primipara, aged twenty-six, was first seen on December 10, 1937. Her past history was essentially negative. She had had an appendectomy at nine years of age. There was no family history of any multiple pregnancies. Menstruation began at 13.5 years, was always regular every twenty-eight to thirty days, lasting for four to five days. She passed no clots and had no pain. The last menstrual period was on August 27, 1937, and the estimated date of confinement was June 4, 1938. The patient weighed 108 pounds at the time of her first examination. She stated that she was having moderate nausea and vomiting and that her breasts were enlarged and sore. She had no urinary symptoms. Her general physical examination was negative. Blood pressure was 120/80, urine entirely negative. Measurements were adequate. Notation on chart at the time of first examination was: "Fundus to level of umbilicus, unusually large for 3.5 months' pregnancy—cannot hear fetal heart, patient has felt no fetal motion." Patient was seen at regular intervals and because of the size of the uterus an x-ray was taken on February 25, 1938 (Fig. 2) and a diagnosis of triplet pregnancy made.

On March 26 the patient had a blood pressure of 136/90 and the urine was normal. She was given instructions as to her diet, rest, etc. On April 9 the blood pressure was again 138/90 and the urine normal. On April 16 the blood pressure was 138/92 and the urine showed 1 plus albumen. The patient was sent into the hospital on April 18 for observation and treatment. Blood pressure fluctuated between the above readings and 170/110, the urine, however, showed an increasing amount of albumen varying from .5 to 1.3 grams per litre. There were occasional casts and an occasional blood cell. Eyeground findings were nor-

*From the Department of Obstetrics and Gynecology, University of Minnesota.

mal. The patient gained a total of twenty-six pounds during her pregnancy. On April 29 at 2 a. m. labor started spontaneously, pains being moderate in severity and intensity.

At about 11 a. m. when the cervix was 5 to 6 cms. dilated, it was felt that the bag of waters was hindering the descent of the presenting part and it was ruptured artificially at 11:10 a. m. Patient continued in labor and delivered a normal female infant weighing 4 pounds, 5 ounces at 12:23 p. m. An episiotomy was done to prevent any undue pressure on the premature heads and to facilitate the subsequent breech delivery. The second bag of waters was ruptured artificially at 12:35 and the second baby delivered at 12:54 p. m. Following rupture of the membranes the presenting part came down with the cord prolapsed in front of it. The cord was pulsating and the second fetal heart was good so no concern was felt. The second baby was delivered as a persistent occiput posterior with a hand prolapsed beside the face. Following the birth of the second baby, the patient started to bleed abnormally and a diagnosis of premature separation of the placenta being assured, a hand was inserted and the third baby delivered by breech extraction. All the babies cried spontaneously. The two placentæ present were expressed immediately following the birth of the third baby. There was no abnormal bleeding, the patient being under careful observation for some time following the delivery. The patient had an uneventful afebrile convalescence and was discharged from the hospital at the end of ten days. Blood pressure at the time of discharge was practically normal, 130/80, and the urine showed only a trace of albumen.

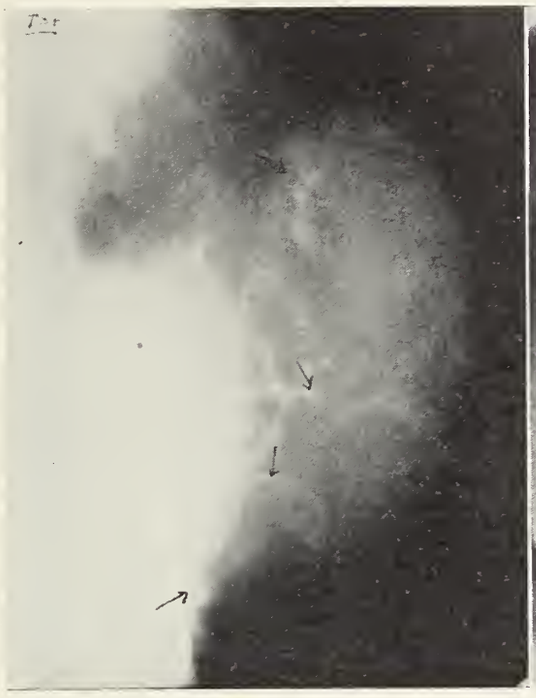

Fig. 1. Case 1.

Fig. 2. Case 2.

The clinical course of multiple pregnancies when more than two infants are present seems to be particularly hazardous for both mother and babies. There have been a large variety of complications reported in the literature. The commonest complications reported in the mother are toxemias of pregnancy, premature delivery, hydramnios, premature separation of a normally implanted placenta, placenta previa and postpartum hemorrhage. In a number of recently reported cases of triplets, the presence of one or two papyraceous feti with only one of the three a normal baby has been observed several times. Malpresentations are common, interlocking in the course of delivery has been reported and placental anomalies are not unusual.

Prostigmine.—Pharmacologic experiments indicate that the prostigmine component of prostigmine compounds possesses some of the properties of the closely allied drug physostigmine. Its actions and uses are similar, but it has the advantage of being more stable. Apparently, it is as active as physostigmine in stimulating intestinal peristalsis and has a similar but somewhat diminished myotic activity. There is no satisfactory evidence that the symptoms produced by toxic doses of prostigmine salts are any less severe than those produced by comparable doses of physostigmine or its salts. Atropine is the antidote to prostigmine. Prostigmine preparations have been used experimentally for the prevention of atony of the intestinal and bladder musculature, and for the symptomatic control of myasthenia gravis. Prostigmine is available only in the form of its salts.—*New and Non-Official Remedies.*

HISTORY OF MEDICINE IN RAMSEY COUNTY

BY J. M. ARMSTRONG, M.D.

IN the year 1835, the Rev. Thomas S. Williamson, M.D., with other missionaries, arrived at Fort Sneling. Dr. Williamson was a graduate of Jefferson College, Canonsburg, Pennsylvania, in 1820, and of the Yale Medical School, in 1824. He was born in the Union District of South Carolina in March, 1800. Previous to his ordination as a Presbyterian minister he had practiced medicine at Ripley, Ohio. He, with others, was appointed by the Presbyterian and Congregational Churches through their joint Missionary Society to visit the Dahcotas with a view of ascertaining what could be done to introduce Christian instruction. Williamson was stationed at various points in Minnesota, or Michigan Territory as it was till 1838, when Wisconsin Territory was established. In 1846, he was at Kaposia, an Indian village located somewhat up river from the present site of South Saint Paul, and was still stationed there in 1851. As he was sent there to administer to both the spiritual and the physical needs of the Indians, it is probable that his medical services were required and used by residents of this vicinity; in fact, his account book shows memoranda of charges for services and medicines to residents of this vicinity during those years. Until 1838, however, the present site of Saint Paul was part of the government reservation and there were no settlers here except squatters until after that time. In his ministerial capacity Williamson performed on the 27th of May, 1835, at Fort Snelling the first marriage service in which a clergyman officiated within the present State of Minnesota, and, one may perhaps add, the first performed by a physician. It is not necessary to go further into Dr. Williamson's career here except to state that he played an important part in the early years of our history, as is evidenced by the frequency with which his name and letters appear in our histories, and the numerous papers he read before the Minnesota Historical Society. He also translated the Bible into the Sioux language. An interesting paper by him on "Diseases of the Dakota Indians" may be found in Volume IV of the *Northwestern Medical and Surgical Journal,* Saint Paul, 1874.* He died at St. Peter, Minnesota, June 24, 1879. To refer to his account book, one sees that his charges for medical services were modest and that he seldom received money for them, being paid mostly in beef, potatoes, and grain. An item for the year 1843 is of interest as it shows that Dr. Turner, of Fort Snelling, apparently was away on leave. This item is as follows:

"For attending on the Garrison and Indians for Dr. Turner, three months and eight days, $229.00. For private practice while living near Fort Snelling, $110.06."

The six cents must have come in some way through the price charged for drugs.

Fort Snelling, at first called Fort St. Anthony, was established as a military post in the year 1819, though the present site was not occupied until 1821. There have always been one or more army surgeons there, and their services were often sought by our early residents. Surgeon Edward Purcell was with the troops

*See also Sibley Letters in the Historical Society library.

that established the post. He was a Virginian, though Irish by birth, and entered the army in 1813, dying at Fort Snelling, January 28, 1825. He was the first United States officer to die in Minnesota, and again, perhaps one may say, the first physician. Purcell's activities will be taken up in a separate chapter. Purcell was succeeded at Fort Snelling by Surgeon B. F. Harney (entered the army in 1814, died 1858) with Robert C. Wood (1800-1869) as assistant surgeon. The latter became surgeon in 1829 and was married that year at Fort Crawford, now Prairie du Chien, to the oldest daughter of Col. Zachary Taylor (later President). Jefferson Davis (later President of the Confederate States) was his brother-in-law. Both Taylor and Davis, then a lieutenant in the army, were stationed at Fort Crawford. During the Civil War, Dr. Wood was Assistant Surgeon-General.† Other surgeons stationed at Fort Snelling were Nathan S. Jarvis (entered the army in 1813 from New York, died 1862), Fitch, in 1837, and George F. Turner, in 1843 (entered the army from Virginia in 1825, died 1854), Joel Martin, who was succeeded in 1849 by Adam N. McLaren (entered the army 1833, died 1874). Whether any of the last named attained to fame as physicians or surgeons is not known. Turner, however, is of particular interest, as his report on an epidemic of scarlet fever at Fort Snelling appears to be the first contribution to a medical periodical from Minnesota. One army surgeon, not yet mentioned, stationed at Fort Snelling was John Emerson (entered the army in 1833, discharged 1842), the owner of Dred Scott, the negro slave whose suit for freedom, because of his residence here, was carried to the Supreme Court of the United States and settled by the decision of Chief Justice Taney. Dr. Turner cared for the pioneer settler, A. L. Larpenteur, in 1847 or 1848, for typhoid fever, which is stated to have been very prevalent here then, as it was up to some thirty-five years ago. Perhaps another man is worthy of note here, though he played no part in the medical history of this state. In October, 1823, one John Marsh, a Harvard graduate of the preceding spring, arrived at Fort St. Anthony as tutor for the colonel's children and conducted the first school in Minnesota. While at the Fort, he studied medicine under Doctor Purcell; in fact at college he had taken courses in anatomy and some medical instruction with Dr. John Dixwell of Boston. It was Marsh's intention to return to Harvard at the end of two years and obtain an M.D. degree; but fate willed otherwise, for instead of returning to the East, he followed the frontier as it moved westward and finally, in February, 1836, found himself in Los Angeles. Being without funds, the most convenient occupation to adopt seemed to be that of a physician. So we find Marsh the first American to practice medicine in California. He had a colorful career and occupied a somewhat prominent place in early California history.‡

In 1838, the land east of what is now Seven Corners, Saint Paul, was opened for settlement and a few white people and half-breeds settled there, most of them engaged in supplying the soldiers and Indians with whiskey. In 1840, the commanding officer at Fort Snelling, in an effort to stop this nefarious trade, expelled from the military reservation, then extending to our present Seven Corners, those squatters still on the government land. Among those driven from the reservation was an Abraham Perret (Perry), a Swiss, who came here as early as 1827. He came from Lord Selkirk's unfortunate settlement on the Red River of the North. Perret lived about where the Ancker Hospital now stands. His wife, Mary Anne, who had seven children, enjoyed quite a reputation as a midwife, and it is stated that she was employed in that capacity several times by the army women at Fort Snelling, who for this reason urged the Commandant

†For biography see *Medical and Surgical Reporter.* Phila., 20:275, 1869.
‡John Marsh, Pioneer, by Dr. George D. Lyman, Charles Scribner's Sons, 1930.

not to expel the Perrets with the other squatters. One of Mrs. Perret's daughters, Adele, who became Mrs. Vetel Guerin (died December 21, 1914, aged eighty-seven years), also was called upon in the early days to serve her sex in the same capacity. The Guerin cabin was on the bluff side of Kellogg Boulevard just below Wabasha.

The first white child born within the present limits of Saint Paul was Bazille Gervais, born September 4, 1837 (died in Saint Paul, 1926). Who was the accoucheur there is now no means of knowing. The first white female child born within the present limits of our city was Cleopatra A. Irvine (Mrs. Richard L. Gorman), daughter of John R. Irvine. She was born March 1, 1844, in a log cabin which stood a few feet from the present northwest corner of Kellogg Boulevard and Franklin Streets. Here an Indian squaw and Mrs. Scott Campbell, a half-breed woman, acted as obstetricians. Mr. A. L. Larpenteur's first child, Mrs. Harris, was born there September 22, 1847, and Mrs. Scott Campbell was again the attendant. The Irvines were the second American family to settle there and the Larpenteurs the fourth, so that births could not have been frequent in the early forties. Mrs. Harris was the first female child born in Saint Paul after the town was plotted and received the name Saint Paul (July 25, 1847). Before that time the general locality was successively known as Kaposia, Pig's Eye, the nickname of Pierre Parrant, and later more specifically as Saint Paul's Landing, Saint Paul's, and finally Saint Paul.

From this time on perhaps the best plan of procedure for continuity will be to take up the medical history of the county by years, as it is easier to follow in that way.

1847

In this year, two physicians arrived in Saint Paul's; one came on July 15 to look over the ground and returned on October 15 to remain there the rest of his life. He was Dr. John Jay Dewey.

Dr. Dewey was born September 9, 1822, in Butternuts, now Morris, Otsego County, N. Y. His parents were Ebenezer and Lucy Webster Dewey, and the family, a Connecticut one, had lived in Lebanon till 1814 when they moved to New York state. Dewey's parents were neighbors of the parents of Dr. William Beaumont, at Lebanon. The father, in his day, was a lawyer of some note and it is said at one time tutored in Greek in Yale College. Doctor Dewey received his education at Hamilton Academy, which later became Madison University, and after completing his course there entered Albany Medical College at Albany, New York, where he graduated early in the year 1847, having attended the school for a period of three years, and having had Drs. Joel Lull and A. P. Strong of Laurens, N. Y., as preceptors for thirty-two months. Several years prior to this time his elder brother, Nelson Dewey, had removed to Wisconsin Territory, and he became the first governor of the state. Through his brother's influence, young Dewey came west after his graduation and went to Lancaster, Wisconsin, then the capital of that state, where he remained till he came to Saint Paul's. When Wisconsin was admitted to statehood it was obvious that a new territory would be organized to the west, and that the seat of government would be a desirable place to locate; still better would it be if one could arrive early and become established. It was surmised correctly that Saint Paul's would become the capital, and no doubt this circumstance induced Dewey to go there. In 1848, Dr. Dewey, with Charles Cavileer, opened the first drug store in Saint Paul's and the first in the area which became Minnesota Territory the next year. In 1849 he was elected to the first territorial legislature. He retired from the drug

business about 1854 and continued to practice medicine, though, having accumulated a sufficient amount of property to satisfy his needs, he never attempted to extend his clientele. On December 20, 1862, he was commissioned Assistant Surgeon, Ninth Minnesota Volunteer Infantry; he resigned September 11 of the following year and returned to Saint Paul. In 1852, he married Elizabeth Ann Barbour (nee Cannon). The late General Wm. G. LeDuc, of Hastings, who knew Doctor Dewey in 1850, said:

"Dewey was an excellent, quiet, undemonstrative man of sense, medium sized, stocky is the word, dark eyes and hair, and clean shaven in the early days."

About 1870, he retired from all business activities and led a quiet life till his death from pneumonia, April 1, 1891. His residence in the Directory of 1856-7 is given as "Saint Paul Street (now Olive) below Somerset," where he also had his office, and in this neighborhood he lived till the time of his death. He was a cousin of the late Admiral Dewey, U.S.N., and his son, Dr. James J. Dewey, who was born in Saint Paul in 1855. Dr. James Dewey graduated in medicine from Rush Medical College but retired from practice some forty or more years ago (died January 2, 1934). Dr. Dewey, Sr., retired from practice before the present Ramsey County Medical Society was formed. By the kindness of Dr. James J. Dewey and his sister, Mrs. George Bell, of Saint Paul, the Ramsey County Society possesses a photograph and autograph of Dr. John J. Dewey, his medical diploma, some of his instruments, matriculation cards from the Albany Medical College, and his military commissions.

Sometime in the year 1847 there arrived a young Virginian by the name of Wm. C. Renfro, a cousin of Henry Jackson (our first American settler, who came to Saint Paul in 1841). Renfro is said to have been a man of ability and education with pleasant and affable manners. He had studied some medicine but probably never graduated from a medical school and had never practiced medicine. Unfortunately, he was too convivial in his habits. On January 3, 1848, his body was found clothed only in his undergarments under a tree near the present northwest corner of Ninth and Locust Streets. It seems he rose in the night and started to town for another drink and was frozen to death. Nothing further seems to be known about Renfro. Possibly, one might say that he was the first physician who died in Saint Paul.

Since we have just recorded the first death of a physician in Saint Paul, we might also record the name of the first physician born there. Newspaper records state that Dr. John George Kittson died in Saint Paul, May 10, 1884. One paper gives his age as forty years and another as thirty-eight. The records at McGill University, however, show that he gave the date of his birth as August 16, 1844, and the place Saint Paul's, which was the name of Saint Paul at that time. He entered the medical school at McGill in 1864, but for some reason did not attend the session of 1867-68 and graduated with the class of 1869. He practiced medicine at Berthier, Canada East (Quebec). In 1875, he became the first chief surgeon for the Royal Northwest Mounted Police. He returned to Saint Paul broken in health, in 1882, and died at the home of his father, Norman W. Kittson. It is known that Norman W. Kittson did not take up his permanent residence in Saint Paul until 1854. Dr. Williamson's account book contains no record of Dr. Kittson's birth, so one might presume that Mrs. Abraham Perret or Mrs. Scott Campbell, who were here at that time, were present when he was born.

To divert again from the narrative, it may be stated that the first resident of Saint Paul to graduate in medicine was Freeborn F. Hoyt. The Hoyts came to

Saint Paul in 1848. Hoyt attended Rush Medical College in 1850, and after graduation established himself in Red Wing, where he practiced till he retired, some years before his death.

As previously stated, the army surgeons at Fort Snelling were frequently called upon professionally by the residents of Saint Paul's. There were other physicians available, notably Dr. Christopher Carli, of Stillwater, who settled there as early as 1841. Dr. Carli was frequently called over to Saint Paul. Mr. A. L. Larpenteur has related the following incident:

"In the fall of the year when my infant daughter was about a year old, she was taken with fits. We were much alarmed. Doctor Dewey was away so I sent to Stillwater for Doctor Carli. He came. It was cold weather and it took him two days, sometimes, to make the round trip, as it did this time. He came in, looked in the child's mouth, took a lancet from his pocket and lanced the child's gums. In twenty minutes the child was asleep. I could have done it myself had I known enough. Sometime in the sixties we had a reunion at the Sawyer House, in Stillwater, of the old settlers and I sat next to Doctor Carli. I said to him, 'You damned old rascal (we old fellows do not care what we say to each other) 'you robbed me.' On his wishing an explanation, I said, 'You charged me twenty-five dollars for lancing the gums of my baby.' He replied, 'It was twenty-five cold miles over there and I forgot I had to go home again, it should have been fifty dollars.' In those days there was no direct road to Stillwater and the so-called road was mostly covered with hazel bushes at that."

1848

Only one physician, Charles William Wolf Borup, settled in Saint Paul in 1848. He never practiced medicine in Saint Paul, but when in the employ of the American Fur Company as a clerk he practiced medicine. A paragraph written by one of the missionaries follows:

"Dr. Borup, to whom our family is indebted for much kindness, requests—that you would procure and send in a box with the things for the mission, the following books—Bourgery, A Treatise on Lesser Surgery translated by W. C. Roberts and James B. Kissam, Essays on some of the most important articles of the Materia Medica by George Carpenter, W. E. Tuson, Dissector's Guide—Wood and Bache's Dispensatory of the U. S., latest edition. Also inquire the price of Lizar's Anatomical plates. It is difficult for him to obtain these books."

(S. Hall to David Green under date of February 12, 1835. From Archives of the American Board of Congregational and Presbyterian Missions.)

Dr. Borup was born at Copenhagen, Denmark, in 1806 and graduated in medicine in Copenhagen. He left Denmark, March 24, 1827, and went to the Danish West Indies, but did not like the climate there, having contracted yellow fever. He came to the United States in 1828. In 1831 he came west in the employ of the American Fur Company and resided at different times at Mackinaw, Fort Snelling, Leech Lake, Yellow Lake, and La Pointe. He was an accomplished musician, the Borup home being the social and musical center of the town in the early days. In 1852, he, with Charles H. Oakes, who came west in 1825, established the first bank in Saint Paul and the first in the territory. Dr. Borup died in Saint Paul, July 6, 1859. Several of his descendants are well known residents there.

1849

In 1849, Minnesota Territory and Ramsey County were organized and the town of Saint Paul incorporated. Many settlers flocked to the capital of the new territory and by the end of the year the population of the city was about 250 to 300. There were thirty dwellings by actual count on April 23. E. S. Seymore, under date of June 18, says:

"I could count 142 buildings including shanties and those under construction; all except a dozen were perhaps less than six months old—at that time there were five physicians."

These five men were John J. Dewey, already mentioned, David Day, Christopher Caldwell, Thomas R. Potts, and Nehemiah Barbour. However, in addition to these five there were two others who came to Saint Paul sometime during the year and may be regarded as more than transient visitors. Biographies of Dr. Day and Dr. Potts will appear later. For the present, we shall narrate only the occurrences relative to medical men and affairs as found in the *Pioneer* for this year. In the second issue of that paper, dated May 5, 1849, in addition to Dr. Dewey's card and an advertisement of Dewey and Cavileer, druggists (who sold tasteless castor oil, among other things), there appears the simple announcement —"Dr. Christopher Caldwell, Physician and Surgeon." This seems to be all that is known about Caldwell. Research and inquiry have revealed nothing more except that a man named Caldwell married a Miss Pierson in Saint Paul, that year. His name does not appear on the census rolls in 1850, so it is presumed that he must have left before that time. Perhaps he had the announcement placed in the paper intending to locate in Saint Paul but did not do so. In the issue of May 12 (third issue) the following notice may be found:

Dr. N. Barbour

The undersigned would respectfully notify the citizens of St. Paul and vicinity that he has opened a

Drug Store

and will keep on hand a good assortment of Drug Medicines, Paints and Dye Stuffs and will also Prescribe Medicines for all those who wish it according to the Eclectic practice, as taught in the Cincinnati Reformed College of Medicine.

This advertisement ran somewhat over a year, and in 1851 a similar announcement appeared stating that he had returned to Saint Paul and would resume practice. There is very little further to be found out about Barbour. He was known to the old settlers as a "root and herb" doctor. He was apparently still living in Saint Paul in 1854, but no more information concerning him is available.

The other two men referred to as being in Saint Paul that year appear to have been unpopular, at least with the editor of the *Pioneer,* as appears from the following items:

Run Away

From Saint Paul, without paying his honest debts, a person in the shape of a man calling himself Doctor Snow, formerly of Prairie du Chien. This is to warn all persons against this man's rascality.
Prairie du Chien *Patriot* please copy.

George Wells.

Sometime later a rumor became current that Dr. Snow had started for Germany, where he had received a handsome legacy, but the Prairie du Chien *Patriot,* noting this, remarked that it was generally understood there that Snow had gone to California. The *Pioneer's* next jibe was sharp:

"We all expected Snow to liquidate before running off, it seems quite evident from all we can learn that the Doctor has not been properly understood here."

This closed the record of Dr. Snow so far as it is recorded or remembered.

(To be continued in next issue.)

The A.M.A. House of Delegates Meeting

TO ONE who has never before witnessed the deliberations of the House of Delegates of the American Medical Association, the special session held September 16 and 17 at Chicago was a revelation. The appointment of committees to consider the resolutions submitted to the House, and the hearings of the committees which could be attended and taken part in by the delegates, assured opportunities for all delegates to be heard. The reports of the various committees later presented to the House were then accepted, modified or rejected. The final action of the House thus represented the majority opinion of the delegates from the states as well as is humanly possible. The idea, often expressed, that policies of the A.M.A. are dictated by a small group of officers, is untenable.

The final action of the House of Delegates has already appeared in *The Journal* of the American Medical Association and should be carefully studied by all physicians. The delegates handled a complicated subject very well. The newspaper reports gave the impression that the profession had stepped into line with the recommendations of President Roosevelt's Technical Committee on Medical Care. As so often happens, the lay press gave the wrong impression. Although the House of Delegates showed throughout its deliberations a desire to coöperate with government agencies in the wise expenditure of funds for the medical care of the needy, it does not recognize the need for a yearly appropriation of any 850 million dollars recommended by the President's Committee, and they reiterated their strenuous disapproval of compulsory state-controlled health insurance.

The House of Delegates again recommended the establishment of a federal department of health to consolidate the twenty-seven different public health activities of the government, with a secretary who shall be a doctor of medicine and a cabinet member. They also approved the expansion of Public Health and Maternal and Child Health activities along prevention lines only, and with due regard to economy.

Hospital expansion was recommended where need exists. The wise suggestion is made that the so-called private hospitals be subsidized for the care of the needy rather than that new hospitals be built. It has been shown that private hospitals throughout the country are only 60 to 70 per cent occupied and many are having financial difficulties.

The principle was announced that medical care of the indigent is a local problem and should be handled by local government from tax funds and with the coöperation of the local medical profession. Doubtless some communities and states may require federal assistance in the form of financial and technical aid, but no general federal subsidy is advocated. It is not difficult to appreciate that higher taxes only depress busi-

ness and increase the burden of the medical care of the indigent. It is wiser for the states to use every endeavor to improve economic conditions which affect the health of our citizens.

Heretofore the various hospital service insurance organizations have received little official support from our national organization. At this meeting, however, the movement which has shown a mushroom-like and healthy growth throughout the country was approved and, providing it does not include doctors' fees, its expansion is urged. Cash indemnity insurance plans to cover in whole or in part the costs of emergency or prolonged illnesses were deemed practical. It is not the occasional need for a doctor that proves a burden for the low income group, but the serious accident or prolonged illness which as a rule requires hospital care. One wonders whether insurance to cover this contingency would not be as popular as that covering hospital bills.

It can be seen that the recommendations of the House of Delegates agreed with the statements submitted by Dr. Braasch on the standpoint of the House of Delegates of the Minnesota profession as expressed at its special meeting September 11.

Pneumococcic Meningitis

THE invasion of the meninges by the pneumococcus is attended by a high mortality rate. This type of meningitis occurs most commonly as a complication of pneumonia, middle ear infections, and skull fractures. Rarely, the meninges may be attacked without any demonstrable primary focus. Until recently, all therapeutic procedures have yielded disappointing results.

Recent reports indicate that, with the introduction of sulfanilamide into the treatment of bacterial infections, a promising therapeutic approach for patients with pneumococcic meningitis has been made possible. Allan and his associates at the Johns Hopkins Hospital have had three patients with pneumococcic meningitis who recovered following the administration of sulfanilamide. Finland and his colleagues at the Boston City Hospital have also presented an important report concerning the use of sulfanilamide alone or in combination with specific antipneumococcic serum in the treatment of ten patients with pneumococcic meningitis, six of whom recovered. In contrast to these results, before the introduction of sulfanilamide, ninety-nine patients were treated at the same institution between November, 1929, and June, 1936, and none recovered. Many of these patients had been treated with specific antipneumococcic serum. These workers believe that a combination of sulfanilamide and specific antipneumococcic serum is more effective than either one alone. The principles of treatment which they have adopted at present include the administration of large doses of sulfanilamide by mouth or subcutaneously; the intravenous injection of specific antipneumococcic horse or rabbit serum; the intrathecal injection of the patient's own serum obtained after he has received the specific serum intravenously; and frequent drainage by lumbar puncture. Sulfanilamide need not be given intraspinally since it appears quickly in the spinal fluid in adequate amounts when given orally or subcutaneously. On the other hand, the specific serum must be introduced into the spinal canal, since it cannot be demonstrated in the fluid when given intravenously. Fresh human serum also must be introduced intraspinally in order to provide complement, which is necessary for the destruction of the pneumococcus. If the patient's serum is not available, small amounts of normal fresh human serum and specific antipneumococcic serum may be given. In one patient treated successfully in this manner, there were 20,000,000 colonies of pneumococci per cubic centimeter in the spinal fluid prior to treatment.

Although the number of patients treated by these workers is small, the results warrant the trial of their methods by others. It will be important to determine in the future whether a combination of sulfanilamide and specific antipneumococcic serum is not more effective in the treatment of cases of pneumoccic pneumonia than sulfanilamide or serum alone.

The paper of Finland and his associates* merits the attention of anyone interested in careful clinical investigation. The protocol of each patient is included with a discussion of the clinical, bacteriological, and immunological studies employed.

WESLEY W. SPINK, M.D.

President Coffman

THE sudden passing of Lotus Delta Coffman, president of the University of Minnesota, ended the career of one who had reached the top in his chosen profession—that of an educator.

President Coffman was born on a farm near Salem, Indiana, January 7, 1875; graduated from the Indiana Normal School at Terre Haute, Indiana, in 1896; received his A.B. degree in 1906, and his A.M. degree in 1910, both from the University of Indiana. In his younger years he taught in country schools, acted as superintendent of schools, director of teacher training, and university teacher, until he took his Ph.D. degree at Columbia in 1911. From then on he taught,—first at the University of Illinois, from 1912 to 1915, when he came to the University of Minnesota. Here he was Dean of the College of Education for six years, until he was named fifth president of the University in 1921, to succeed Dr. Marion Leroy Burton.

During President Coffman's seventeen years as president, the University has shown tremendous development. The enrolment has doubled and the annual budget nearly so. Many new buildings, as well as several new departments, have been added to the University.

The qualifications of a university president have changed in recent years. Whereas formerly scholastic attainment in the dead languages used to be considered a prime consideration in selecting a university president, now he must be not only an educator but an administrator. President Coffman's training, first as teacher and later in administrative capacities, prepared him for the larger task of presiding over a university when the opportunity presented itself. Interested primarily in education, he still possessed an appreciation of the value of extra-curricular activities. His ability as an educator was recognized during his lifetime by honorary degrees from a number of universities. Minnesota has sustained a great loss in his sudden departure at an age when many more years of usefulness might well have been his lot.

We live worthily when we do work that helps to improve conditions of life for everyone.

STATUS OF THE GLEN LAKE SANATORIUM*

Donald C. Balfour, M.D., Director, Mayo Foundation
Rochester, Minnesota

I appreciate the privilege of being here on this occasion. It is most appropriate that those who have contributed to the growth of a great institution such as this should receive the recognition which is being given here this evening. I feel honored that I have the opportunity of joining in this tribute to Mr. Gale and Mr. Kingman and to those who have given such unselfish support to Glen Lake.

The control of such a devasting disease as tuberculosis is one of the great triumphs of medical science, and if one traces the history of this achievement he will be struck with the fact that it has paralleled the development of sanatoria. It is true that sanatoria for the care of tuberculous patients have been in existence for over a hundred years, because it was in 1791 that an infirmary for such patients was first founded in England, and up to the time of Koch's discovery of the tubercle bacillus thirteen sanatoria for the treatment of the disease had been established in England. In Germany the first hospital for the treatment of the disease was founded in 1853, and the earliest institutions in this country were "inspired by religious and humane motives as early as 1857." The beginning of modern sanatoria for the treatment of the disease in this country, however, is usually dated from the founding of the sanatorium at Saranac, New York, by Trudeau in 1885.

The change in the physical character of sanatoria during the past thirty years is evidence of the general improvement which has taken place in hospitals, but particularly emphasizes that the treatment of tuberculosis is on as scientific a basis as any other disease. Not so long ago the type of sanatoria was represented by a series of small, shack-like structures, and the treatment of the disease was largely a question of isolation, fresh air, and good food. That rest is the first principle in the treatment of tuberculosis was far from being generally recognized. It was found in later years that the principle of isolation was not necessary, and the tendency subsequently has been to construct sanatoria on the same general plan as any general hospital. As a matter of fact the modern sanatorium, as exemplified here at Glen Lake, with its laboratories and operating rooms and facilities for research and for the training of nurses, is so well constructed and equipped that little change would be needed to convert such an institution into a general hospital.

It has been interesting, too, to find that climate is not as important a factor in the treatment of the disease as was once thought, and it has become possible to construct sanatoria throughout all parts of the country so that those afflicted with the disease can obtain the best possible care without the serious disadvantage of going far from home.

The particular functions of a sanatorium, in contrast

*Presented at the dinner to honor the 25th Anniversary of the Hennepin County Sanatorium Commission held at Glen Lake Sanatorium, September 9, 1938.

to home treatment of the tuberculous patient, are the prevention of the spread of infection, the education of the patient and family and friends, the cure and arrest of the disease, particularly in advanced cases, the training of physicians and nurses for specialization in this field, the economic rehabilitation of the patient, and usefulness as a diagnostic center, furnishing facilities for preventorium care as well as for research and development of surgical methods of treatment of the disease. In all these functions the modern sanatorium has no superior and should continue to lead the way in further advances in our knowledge of this disease.

The control of tuberculosis has been accomplished to a great extent through methods of education and in this the sanatorium has had such a large part that public support and approval have been freely given. The fact that the majority of tuberculosis hospitals are community projects and have been developed with very little assistance from the federal government, which has limited its aid in tuberculosis largely to those patients who are direct wards of the government, will always be an example of what can be done by the community itself. As an example of the extent to which support by public funds is given, it has been shown that in 1908, 34 per cent of the sanatoria were supported by public funds, whereas in 1931 the figure had risen to 78 per cent. In other words, it is obvious that if the public can be convinced of the desirability of a program for the control of a disease and can see that the program is being satisfactorily carried out public support will not be lacking.

No better example of what a sanatorium should be and how it should be run in the estimation of both the public and profession can be found than here at Glen Lake, for it is generally agreed, among those who know, that in Glen Lake, Minnesota has a sanatorium which is unexcelled. The growth of Glen Lake has been steadily toward more scientific management of the disease, and the publications of the staff are recognized as being the observations of men of authority because of high scientific training and experience. An example of the standard of medical practice here is the accomplishment of the staff in carrying out successfully, for the first time in Minnesota, the complete removal of a diseased lung. The influence of such an institution on medical thought and practice is of the greatest importance, and I am glad at this time to express on behalf of the Mayo Foundation our appreciation of the opportunities which Glen Lake has afforded the members of our staff and the Fellows of the Foundation to study here. From the standpoint of graduate medical education we believe that no better opportunity can be found for scientific study of tuberculosis and its treatment than at Glen Lake.

Minnesota can well be proud of those who have made Glen Lake so outstanding. The tribute this evening to Mr. Gale and Mr. Kingman is significant since it is evidence of what can be accomplished when an institution is directed by men who have no other motive than to see that the highest possible medical service is rendered. I consider it an honor to join in the tribute to Mr. Gale and Mr. Kingman, who have had such a large part in the development of this institution.

In Memoriam

Axel W. Swedenburg

1873-1938

DR. AXEL W. SWEDENBURG, of Thief River Falls, died at his home August 20, 1938, from a stroke, at the age of sixty-five. He was born April 6, 1873, at Maiden Rock, Wisconsin. After finishing high school he acquired a Bachelor of Science degree from Valparaiso University. In 1903, he began the study of medicine at the Chicago College of Medicine and Surgery, and received his M.D. in 1907. The same year he married Elfrida Ericson, who passed away in 1913.

After finishing his internship, Dr. Swedenburg practiced at Ellendale, Minnesota, until 1910, when he moved to Thief River Falls. In 1914, he moved to Ashland, Oregon, where he practiced two years with his brother, Dr. Francis Swedenburg, returning to Thief River Falls in 1916.

On October 1, 1917, Dr. Swedenburg was commissioned first lieutenant in the Army Medical Corps and served at Jefferson Barracks and Fort Riley, being honorably discharged December 29, 1919. Since then he continuously practiced at Thief River Falls until two years ago, when he was forced to retire because of ill health.

Dr. Swedenburg was active in local affairs in his home town. He was one of the organizers and the first president of the local Rotary Club. He was affiliated with the local Masonic lodge and was a member of the Elks and Odd Fellows. He was a member of the Lutheran Church and was also a member of the Elmer J. Eklund Post No. 117 of the American Legion, which conducted a military service at the cemetery at the time of his funeral.

Dr. Swedenburg had practiced for over twenty-five years at Thief River Falls and was a member of the Red River Valley Medical Society, the Minnesota State and American Medical Associations. He also belonged to the American Railway Surgeons Association.

In 1919, Dr. Swedenburg was married to Mina Rock at Iowa City, Iowa. He is survived by his wife; one daughter, Mrs. Dorothy O'Connor of Saint Paul, two sons, Carl W. of Saint Cloud and Donald of Thief River Falls.

Fannie Kimball Fiester

1866-1938

Dr. Fannie Kimball Fiester died at her home in Austin, Minnesota, May 6, 1938, after a day's illness.

Dr. Fiester was born in West Randolph, Vermont, May 6, 1866. She received her early education in the city of her birth, and graduated from Northwestern University Women's Medical School in 1891. She received her M.D. from Hahnemann Medical College in 1893 and served her internship in the Iowa State Hospital at Independence, Iowa.

Locating in Austin in 1893, Dr. Fiester practiced continuously until the day before her death.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
W. F. Braasch, M.D., Chairman

LAST STEP IN THE SURVEY

Form 1-F, last step in the survey, went to all members of the Minnesota State Medical Association, September 24.

This form was designed to provide a check on the facts reported previously on Form No. 1. A careful record was to be made on it each day for the week beginning September 26 of the number of patients given care without charge, or those referred to agencies and from agencies for service.

This check is an essential part of the survey. Every member is urged to keep the record carefully and send it promptly to the secretary of his county or district society.

The American Medical Association has recommended that new appropriations for extensions of public health and medical programs be governed by the need in each community. It is the business of physicians to show where that need is.

THE SPECIAL SESSION OF THE HOUSE OF DELEGATES

THE recent special session of the House of Delegates of the American Medical Association was an epoch-making event in the annals of that representative body. There was much speculation on the eve of the gathering as to what action would be taken. Vague rumors were circulated that radical plans would be proposed by some of the members.

A plan for the spending of the 850 millions of federal money included in the National Health Program had already been adopted by one state medical society. Several of the state societies had encouraged the establishment of local health insurance plans.

New Plans Blossomed

In fact, during the last six months new plans for medical care have blossomed out almost daily in county medical societies throughout the land. The threat of governmental action, claims that many physicians were leaning toward socialized medicine, and criticisms of the attitude of organized medicine appearing in countless newspapers and periodicals all conspired to make some of us conservatives rather jittery as to what might happen on the morrow. That these influences affected the reactionary attitude previously held by many of the delegates is undoubtedly true.

Wisely Guided

However, as so often has happened in previous meetings of the House of Delegates, apparent crises were smoothly compromised and the action taken was generally satisfactory. The modus operandi for consideration of the problems confronting the delegates was well conceived and functioned exceedingly well. A general committee of twenty-five was appointed which was subdivided into groups of five. Each one of the subcommittees was assigned to the consideration of one of the five sections in the National Health Report. The choice of the general chairman, Dr. Walter Donaldson, was a wise and happy one, and he guided the deliberations of the various committees in a wise and masterly fashion.

The personnel of the subcommittees included many men who had given much previous time and thought to the subjects under discussion. The various subcommittees met separately to consider the subjects involved in the sections assigned to them. Opportunity was given to any delegate who so desired to appear before them and express his views.

The results of the deliberations and the final resolutions adopted undoubtedly represented the opinion of an overwhelming majority of the members present.

Sympathetic Attitude Adopted

Although the government health program was based on inadequate information and was not well considered and in spite of the fact that many of the members objected to many of its proposals, nevertheless they adopted a sympathetic attitude towards the "magnificent" objectives. Al-

though the House of Delegates endorsed the spirit of the proposals embodied in Sections I and II of the Health Program, important reservations were made which did not appear in the press. *These reservations included, first, that medical services should be expanded only in areas where they were needed, and, second, that those measures should be taken in coöperation and with approval of local medical societies.* These two very important reservations should make the proposals acceptable to the medical profession without hampering their application.

Insurance Principle Accepted

Another outstanding feature of the program adopted by the delegates is the acceptance of the principle of health insurance. While certain features of insurance never have been opposed by organized medicine, nevertheless its present attitude toward the subject permits more liberal interpretation than formerly. Reservations were made, however, which limit insurance to voluntary insurance and under the guidance of the local medical societies. *The resolutions definitely stated opposition to compulsory insurance with government aid.*

The approval of the wide expansion of the hospital facilities and the establishment of numerous diagnostic centers as suggested by the National Health Program was qualified. While the need of greater hospitalization was recognized in certain areas and in the care of certain diseases, nevertheless the hit-and-miss expansion as proposed was disapproved. A plea was made for more intelligent employment of facilities already existing and that any expansion be limited to rural areas and other fields as specified.

It is of interest that the Committee approved the principle of hospital insurance, which is being widely adopted throughout the country, and recommended it as a community project.

The Committee recognized the soundness of the principles of workmen compensation laws and recommended the expansion of such legislation to provide for meeting the cost of illness resulting from industry.

It is of interest that the Committee endorsed the principle of compensation for loss of wages during sickness.

3,000 Medical Society Plans

In the course of discussion, Dr. Leland called attention to the fact that over 3,000 plans are now filed in the Bureau of Medical Economics which have been proposed by medical societies and other medical agencies to provide for more adequate distribution of medical care. It is to be hoped that these plans and the action of the House of Delegates will refute insinuations which have appeared in many publications that the medical profession is not doing all it can to give the public the best possible medical care.

The sympathetic attitude of the delegates toward the National Health Program should refute accusations which have been made that the medical profession is opposed to health reform because of selfish motives. It should emphasize the fact that they had only one object in mind and that is the protection of the best traditions of medical practice.

In order to show their desire to coöperate with the federal authorities in carrying out the National Health Program, a standing committee was appointed by the speaker of the House for the purpose of conferring with them. It remains to be seen whether they will be met by the federal representatives with a similar spirit of coöperation.

W. F Braasch, M.D.

ACTION BY THE DELEGATES

The Board of Trustees was definitely instructed by the House of Delegates in Chicago to oppose the attempt initiated by Attorney General Thurman Arnold to convict the American Medical Association of monopoly. Monopoly was charged by Attorney General Arnold on the strength of opposition to illegal aspects of the Group Health Association of Washington, D. C., employees of the Home Owners Loan Corporation and an investigation threatened.

Any action that may fix upon the association this charge will be fought, if necessary in the courts of last resort.

The Delegates also unanimously rejected a resolution which would have encouraged medical societies to set up group plans and advertise them to the public.

A committee of seven physicians including Dr. Irvin Abell, Louisville, Ky., president; Dr. Henry A. Luce, Detroit; Dr. Frederic E. Sondern,

New York; Dr. Walter E. Vest, Huntington, W Va.; Dr. Walter F. Donaldson, Pittsburgh; Dr. Fred W. Rankin, Lexington, Ky.; and Dr. Edwin H. Cary, Dallas, Texas, was appointed to confer with federal authorities on methods of coördinating health and welfare activities of private practitioners and government health and medical workers.

AS MINNESOTA SEES IT

County officers, delegates and committees met in special session at the St. Paul Hotel, Sunday, September 11, to discuss the government health program and instruct Minnesota delegates to the Chicago session.

It is interesting to note that Minnesota's action anticipated in a general way the more detailed action taken at Chicago.

The Minnesota officers and committees—130 in all from all parts of the state—went on record to the effect that:

Minnesota's Platform

We in Minnesota are in sympathy with all intelligent efforts to help indigents and the people with low incomes.

We insist, however, that any plan adopted or any program proposed leave to the medical and health authorities of each state the exact form and extent of the program from that state.

We insist, also, that the right of freedom in choice of physician be preserved.

We are opposed to any form of tax-supported compulsory health insurance.

This action was taken after a day of discussion by state officers, by representatives of the State Board of Health and the State Board of Control now in charge of Social Security aids to public health and medical care, and others.

Excerpts from important talks made at the Sunday meeting follow.

Important Epoch

Dr. J. M. Hayes, Minneapolis, president of the Minnesota State Medical Association and presiding officer at the conference:

> We have reached an important epoch in our history. Are we or are we not going to let the politicians tell us what to do?

We have an arrangement in Minnesota whereby the medical profession is consulted on the expenditure of nearly all relief and welfare funds devoted to medical care and the public health. Our close coöperation with the official agencies has made it possible for any indigent person in Minnesota to receive excellent medical care when he needs it.

Our great problem is to fight false impressions created in the public mind by backers of the so-called National Health Program.

Doorbell Survey

This program is built largely upon statistics gathered in the W.P.A. "doorbell survey." And, in this connection, I would like to say a word about that survey. I had occasion, myself, to follow up the work in several families and I found that even where the people interviewed had been under the care of a naturopath they were listed as having received medical care. In many instances the people interviewed had answered carelessly and without any attempt whatever at truth or exactness. It is on the basis of such a study that the President's Inter-departmental Committee is now claiming the low income class lacks adequate medical care.

The public is easily deceived, however. Mr. Paul Kellogg declares in a recent issue of *Survey Graphic* that the W.P.A. survey was "the greatest medical survey in the history of American Medicine."

It is clear that we must find some way to counteract such statements in the public mind.

Dr. W. F. Braasch, Rochester, chairman of the Committee on Medical Economics: The program of the National Health Conference (where the President's committee proposed its program) was definitely a "set-up." The atmosphere was radical and antagonistic. When the representatives of organized medicine, Dr. Abell, Dr. West and Dr. Fishbein, told the conference what medicine has already done and what it proposes to do, they were greeted with silence. The doctors were outcasts and no representatives of banking or industry were present.

A number of different plans will be under discussion in Chicago next week. One, at least, will be very liberal. I hope you will instruct your delegates to carry down to Chicago a conservative, well considered program.

Successful Relationship

Dr. George Earl, Saint Paul, president-elect of the State Medical Association: Most suc-

cessful relationships in life are dual relationships. Notable among these dual relationships is that between doctor and patient which the politicians are trying, just now, to make into a triangular relationship of doctor, politician and patient.

We are of one mind, I believe, on the importance of maintaining the dual character of the doctor's relationship to his patient and also of maintaining the freedom of the patient to choose his physician.

We must remember that the public is not very intelligent on any program involving medical care. Also that the politician and social worker are its favorite teachers.

State Medicine Implied

Among other things, the new government program proposes establishment of 500 government-supported health and diagnostic centers in the United States. All of the elements of tax-supported state medicine are implicit in this proposal.

It is probable that we need very few such units in Minnesota because our level of practice is very high. It seems to me, therefore, that the government might rationally assist and enlarge our present facilities instead of building new hospitals and centers here.

Our problem is to present a rational plan that will provide adequate care and still not fasten upon us, unnecessarily a costly system of state-supported medical units.

Inference Untrue

I want to go on record here on the importance of counteracting the inference, attendant upon National Health Conference publicity, that physicians are opposed to the extension to everybody of good medical care. Nothing could be further from the truth.

We believe in the extension of public health services and we believe in insurance. We do not believe in tax-supported, government-controlled compulsory insurance because it will lead to medicine by politically controlled bureas with an overhead cost that may run to 50 and 60 per cent as it has in other countries.

In my opinion we must assure the public that we do stand for the best possible medical care for all the people. Let us show the public a positive program and a true leadership. Let us show them, further, that the doctors and not the politicians are their friends.

Minnesota's Record

Dr. E. C. Hartley, Saint Paul, director of Maternal and Child Welfare, State Department of Health: Since 1915 the maternal mortality in Minnesota has been cut in half. In 1937 the infant mortality was three for every 100 live births and more than 98 per cent were delivered by doctors—a record for the entire United States. Certainly the situation in Minnesota with regard to maternal and child health is an example for the rest of the nation.

If the laws suggested go through, considerable sums of money will undoubtedly be available for this work. I can assure you that any methods that may be adopted will be adopted in consultation with the state medical association. We have always assumed that our function in this respect was purely educational. I am sure that Dr. Chesley as executive officer would offer no other kind of service.

Dr. C. A. Stewart, Minneapolis: We have already a well-rounded public health program in maternal and child health, in nutrition, in prevention of crippling conditions, under Dr. Hilleboe of the State Board of Control, in our school health services, including vaccination and immunization with vaccines and toxoids supplied by the State Board of Health when they are requested. In the main, our child health program is adequate and additional funds would scarcely be needed in Minnesota except to supplement already existing services.

Sufficient Sanatoria

Dr. H. E. Hilleboe, Saint Paul, director of the Division of Tuberculosis and of services for Crippled Children, State Board of Control: There are now sufficient sanatoria to take care of all tuberculous patients in Minnesota. Additional funds for construction of sanatoria will not be needed in this state. Funds are needed, however, to supplement the follow-up care already instituted by the State Board of Control. There is need for further medical supervision of discharged patients, also for funds to provide the necessities of life for the families of patients. There is also a need for facilities to segregate tuberculosis patients among the insane.

There is no need to bring in federal funds to build additional hospitals for crippled children. At the present time social security funds are being used, temporarily, to hospitalize some crippled children in private hospitals. Within two years, however, there will be sufficient beds available at Gillette, the Shriners' hospital and the University hospital to care for the load.

Convalescent Home Needed

The Board of Control is especially interested, now, in providing domiciliary care and convalescent homes for indigent children. There are now 1,300 children in the state who were crippled from birth who need such care. Also there are a number of children with heart disease who should have convalescent care. There is a problem which we as physicians must face in time.

The chairman of the Board of Control has instructed me to inform the members of our association that he and the board will continue to follow the policies that have guided us for the past two years with regard to both the tuberculosis and the crippled child programs.

Dr. Paul O'Leary, Rochester, member of the Committee on Syphilis and Social Diseases: Our Minnesota program for control of venereal disease has been functioning for 18 years and it has functioned so well that it has been set up as a model all over the United States. Some $43,000 has been devoted by the state to the program outlined by Dr. Chesley. Only about 177 doctors have taken advantage of the offer of free drugs which is a part of that program, an indication of the healthy condition that prevails in most communities.

A meeting like this should be of a constructive type. It is our business, now, to present a program for the health situation as a whole that will serve as a model just as our venereal disease program has served as a model in Minnesota.

Cancer Facilities Adequate

Dr. Martin Nordland, Minneapolis, chairman of the Committee on Cancer: Control of cancer depends mainly upon early diagnosis and, certainly, there are ample facilities for early diagnosis of cancer in Minnesota. The importance of the cancer problem should be brought to the physicians, of course, and this has been a large part of the work of our committee.

Dr. H. E. Robertson, Rochester, member of the Committee on Cancer: I am strongly opposed to the carrying out of the recommendations concerning control of cancer which were included in the report of the technical committee and submitted as part of the program of the Inter-Departmental Committee.

Three Phases

The cancer problem resolves itself into three phases: one, research concerning the pathogenesis and cause of malignant growths; two, early and appropriate treatment of these growths (this point involves extensive education of both the layman and the doctor); three, the care of advanced cancer cases, particularly among the indigent.

The stimulus for the study of the pathogenesis and cause of cancer is sufficiently strong so that no urge by government agencies will ever be necessary. The reward of solid contributions in this field is sufficient in itself to keep every worker on his toes. The slightest hint that steps toward the solution of this problem are in sight has produced and would produce adequate funds from private resources to finance fully any such undertaking.

The early diagnosis and treatment of cancer involves a problem that must be solved wholly by the medical profession. In the education of doctors and laymen for the early handling of cancer cases, a program has been established for years by the American Society for the Control of Cancer. It is satisfactorily organized and evidences definitely good results. The establishment of centers throughout the United States for the exclusive study and treatment of cancer might need support from government agencies. But to turn over to these agencies the organization of such an intricate problem in education of doctors and patients and in the medical and surgical handling of cancer cases is distinctly a backward step. One has only to point to the thoroughly inadequate care given in the Veterans' Hospitals of this country to demonstrate the waste and uselessness of such a move.

"Cancer Asylums"

The care of advanced and largely indigent cases of cancer is likely to prove the final de-

velopment of most government plans in this field.

The demands of relatives of cancer-afflicted people and of the patients themselves, for free hospital care, especially when their condition is incurable, would make overwhelming inroads into funds established for cancer control. The result would be the establishment of cancer asylums throughout the country without material benefit to anyone except insofar as they provided free living for these unfortunate people. The resources now available in city hospitals and special cancer clinics are fairly adequate for handling this phase of the cancer problem. These are organized and controlled by medical men and no other lay substitute could be developed which would do a better job.

Supplement Hospitals

Dr. Peter Ward, Saint Paul, superintendent of Miller Hospital and president of the Minnesota Hospital Association: The effect upon the private hospitals of further building of federal hospitals could probably be compared to the effect upon business in general of government interference. Hospital facilities in Minnesota today are sufficient, I believe, to take care of the needs of patients and doctors. There may be isolated communities where facilities are not ideal and government funds can be used as Dr. Earl suggests to supplement and amplify existing facilities.

Incidentally the Minnesota Hospital Association enjoys a membership of 98 per cent of all the hospitals in the state. In the Hospital world this is a unique record and evidence of the general excellence of our hospital facilities.

Dr. Orianna McDaniel, Saint Paul, director of the Division of Preventable Diseases, State Board of Health: About one-third of the 2,000 or more pneumonia deaths that occur on the average each year in Minnesota could be prevented by use of serum. This would mean a saving of at least 340 lives each year.

Since federal money became available our board has set up a state-wide program of pneumonia control. The objectives were to assist physicians in diagnosing pneumonia and to furnish serum to needy persons. Typing centers have been set up in various parts of the state, 67 of them in the hospitals and others at the health unit districts. It is left to the physician to determine whether or not the patient is needy and should have the serum furnished by our board. Before serum is sent, sputum must be typed and a report telephoned to the Board. This work is in its infancy and much still remains to be done in the way of publicity both to the public and the doctors.

Dr. A. J. Chesley, Saint Paul, executive officer and secretary of the Minnesota Department of Health: This situation has seemed serious to the health officers for a long time. We have tried to warn the practicing profession and I am glad to see that organized medicine is now thoroughly aroused.

One thing we must all remember. The public will look at health and medical problems from a national rather than from a local point of view. When Minnesota people hear on the radio that one-third of the people of the United States lack adequate medical care, that only five per cent of those who need it receive pneumonia serum, they are going to apply those figures, based on the national W.P. health survey, to Minnesota. We must not be too irritated on that account.

Figures Do Not Apply

Actually we know that those figures do not apply to Minnesota at all. Incidentally, even a United States Public Health official who was organizing the "doorbell survey" was unable to answer all of the 62 questions that untrained numerators were required to ask in their house-to-house survey. That fact indicates that the figures so widely quoted may not always be accurate or reliable.

It is practically impossible to find out by a survey just how much disease there is and to estimate on that basis just how extensive the medical facilities must be to take care of it. It IS possible, however, to compare death rates and, even more significant, the rate of deaths at which no physician is in attendance.

Few Unattended Deaths

We have just discovered in a study made recently by one of our staff that only one-tenth of one per cent of deaths in Minnesota last year were unattended by a physician. That is an important finding, especially when it is compared with the record of Mississippi, where

15.5 of the death certificates were not signed by a physician last year.

In a situation of this sort the State Board of Health is between two camps. We have already done our best to work with the doctors in Minnesota. On the other hand, when large sums of money become available to the states, congressmen demand that the people in their districts get their share.

If our present plan for utilizing federal funds can be followed, we shall be doing the best that can be done, I believe, at the present time. It should be remembered that federal grants are not flat grants, they must be matched by state funds.

Surgeon General Parran is a very competent man but he is on the spot. In any case, he is bound to confer with the conference of state and provincial health officers before he recommends appropriations.

Lesson from Canada

It seems to me that we might take a lesson from Canada's system and experience. In Canada, the final decision on all extension of medical care still rests with the organized medical profession. In some instances legislation that was not approved by the physicians has been passed. But the doctors refused to work under the legislation and new regulations have had to be made. Undoubtedly we can do the same thing, if we wish, in the United States.

Every Precaution

Every precaution must be taken to avoid the appearance of a selfish motive before the public.

We have done our best to provide a good program along sound lines in Minnesota. If we have failed it is not because we have not tried or because we have lacked the close cooperation of the medical profession.

Dr. W. A. Coventry, Duluth: In all this discussion, too little emphasis is placed upon preventive medicine, it seems to me.

Our programs of preventive medicine should be carried on vigorously and amplified if possible. For instance, better mental hygiene would do a good deal to prevent overcrowding of insane asylums and considerable research should be done on this line alone. There is no doubt that hospitals should make some arrangement whereby they can give cheaper service, especially for the man in the low income group. The man on relief must, of course, receive care without cost.

Dr. J. W. Gamble, Albert Lea: Doctors have been too close-mouthed. What we need now is some means of presenting our views to the public as impressively as the views of our critics have been presented. Newspapers, magazines, radio programs, have been full of criticism of the doctors. It is time for the doctors to take the public into their confidence.

Dr. S. H. Boyer, Sr., Duluth: We hear a great deal about "adequate medical service." But what is "adequate medical service"? Actually, we all know that service is a relative matter. What one person might consider adequate service another might regard as neglect. To one person four visits a day might be regarded as adequate service. To another one visit in two days might be ample. Adequate medical service is not an absolute but a relative matter and a matter which causes great difficulty whenever any group plan for medical service is contemplated.

Dr. R. L. Scammon, Minneapolis, distinguished service professor of the graduate school of the University of Minnesota: We live in a mixed world. We use public water to bathe in a private bath with private soap. We go down to a breakfast which includes milk that is publicly inspected, in which, in fact, the only private thing is our spoons.

The real question is: where shall we draw the line between the things that are best as public functions and those that are best as private functions.

Medical Secrets

Medicine partakes conspicuously of both a public and a private function. It has always partaken of this dual function. In Rome there were codes for private functions of medicine. Even the barbarians set up their own codes. Such codes can be traced back to Greece and all over the civilized world.

Physicians, in fact, are often said to have medical secrets, to be in secret cliques. Now it seems to me, speaking not as a medical man —which I am not—but as a citizen, that these

medical secrets are essential for the physician. In the same manner, a wife is permitted to have secrets and is not required to testify against her husband. A solicitor also has secrets and if he discloses confidential information given him by his client he may be called before the bar association. In the field of religious belief there are also inviolable secrets. We all have the right of confession, of pouring out our woes secure in the knowledge that our confessor or minister will not be obliged to disclose our confidences.

For Decent Reserves

The same thing is true for the doctor in his private practice. A great many people come to the doctor with all of their personal difficulties and it is necessary for him to preserve that confidence.

No doubt more criminals might be caught if the lawyer or the wife disclosed the information in their possession.

The point is—and a point which I wish to make at the start—there is a certain set of reticences that must be preserved no matter what the cost. These reserves are what make decent society possible.

The advance in the public field of medicine has been most remarkable. But there is another field, the field of private practice, and upon it rests the dignity of man. And while we recognize the field of public medicine we know there are diseases which cannot be cured.

None of us are going to live forever. Our population is changing. We are dealing more and more with degenerative diseases which we can't cure yet. The public as a whole does not understand that fact and it is purely misunderstanding that they do not keep the matter clearly in mind.

Plans Must Be Localized

Now as to insurance, about which I have been asked to speak to you today: I believe an insurance scheme could be worked out in this country but it would have to be a highly localized scheme because our people are so different in different localities. I believe also that it could be worked out so as to keep what I consider to be one of the decencies of civilization, the right of the individual to go to the physician of his choice.

In my opinion, however, we cannot expect to give an extremely high grade of medical care under such a system, any more than we could provide an extremely high grade of shoes or of housing.

Wealth Not Great

This country is the richest in the world and also the most populous of civilized countries. In population it is not to be compared with France or Germany; and, looked at from the point of view of the population, its wealth is not so great.

In the state of Minnesota the last figures we worked out for 1933 showed that the average family income was about $1,750 and that only six per cent of the people were earning $2,500 or more a year. If the total income were divided among the entire population, it would yield a mere $90 a year per person. Obviously, the difficulty in "soaking the rich" is that we should have to use bird shot to do it.

Under a system of voluntary insurance it is possible that the people who need the service most will not purchase it. Certainly life insurance under the voluntary system has not worked. Even in our most prosperous year, 1929, we could insure only enough people to protect us for thirteen months.

"Like a Dinosaur"

In any case there is only so much you can give, just as there are only so many shoes and so much food. Probably it is better to spread it. Certainly it is better to have a local rather than a national system. This is a large country and, like a dinosaur, its head is a long way from its feet.

The system of insurance in effect in England is extremely variable. It works well in the North and not in the South and the fault probably is neither with the system nor the physicians but rather with the English people. The system is largely affected, of course, by the caste system. Many men are eligible and won't accept it because they do not want to be identified with the working class. In any case, it is a grave mistake to think that the system worked out in one country can be lifted and applied as it is to another.

Essential Factors

We have some interesting samples of health insurance in this country but we cannot fol-

low the plan of manufacturing people in any general form of insurance since the manufacturing companies select their people for insurance.

Perhaps the most important factors to be considered are these:

1. The plan would have to be localized.
2. It should not try to do too much, especially on the present income of the United States.
3. It would have to protect the confidential relationship between patient and physician.

In her recent report, Miss Roche gave 4½ per cent as the figure for medical expenditures in this country. That figure is probably wrong since it depends on a discredited study. But compare it with the German figure. In Germany about nine per cent of the worker's income is taken for health.

Everybody a Cousin

In the Scandinavian countries sickness insurance seems to work. I never could understand why, except that Sweden, for instance, is a small compact country and the age distribution is in the wealth-producing period. Also, Sweden did not get into the world war. Instead the Swedes devoted themselves to making money.

As in England, in Sweden everybody is cousin to everybody else. With that close relationship comes a sense of responsibility.

Professional Success

The difference between business and professional success is that success in business lies in making profits and success in a profession lies in the conduct of the job.

We should remember that there is all the difference in the world between maintaining standards which are occasionally violated and abandoning our standards altogether.

"BE ON GUARD"

(Monthly Editorial Prepared by the Medical Advisory Committee.)

Medicine is in the limelight. The public eye is focused on medical practice and medical men. Physicians and hospitals are being censured for the type of medical care which has been and is being given the people, especially those in the low income group.

Your Medical Advisory Committee finds that the great majority of the cases brought against members of our Association and reported to the committee come from the so-called indigent group.

It is easy for a lawyer to build up a case about this type of patient, sympathy is easily raised, and juries are readily swayed to give substantial verdicts.

Your committee warns you against any apparent neglect or indifference to them. Guard your words of advice carefully. Give the same careful consideration to their needs as you would to the man who can pay the highest fee, and keep records.

Remember, once having assumed the care of a case, you must continue attendance until discharged by the patient, until the patient has recovered, or another man has assumed the care with the consent of the patient or legal guardian.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Correspondence School Student Pleads Guilty to Unlawful Practice of Healing

Re: State of Minnesota vs. L. Leo O'Leary

L. Leo O'Leary, 23 years of age, entered a plea of guilty in the District Court, at Moorhead, Minnesota, on August 24, 1938, to an information charging him with practicing healing without a basic science certificate. O'Leary was arrested on August 16, 1938, following the filing of a complaint against him by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners. O'Leary inserted a professional card in the Barnesville Record Review under date of July 7, 1938, reading as follows:

L. LEO O'LEARY
Drugless Therapy
Electro-Hydro Therapy Treatments
Dietetics and Baths
Office at Broadway Hotel
Hours 1-6 and by appointment
Phone 72

O'Leary also furnished the newspaper with a news item in which he referred to himself as a "drugless therapist" and that he had studied at the "National College of Drugless Physicians in Chicago." O'Leary was arraigned before E. U. Wade, Justice of the Peace at Moorhead, Minnesota, on August 17, 1938, at which time he waived his preliminary hearing and was held to the District Court under bond of $300.00, which he did not furnish. After eight days in the Clay County jail, O'Leary entered a plea of guilty before the Honorable Anton Thompson, Judge of the District Court. O'Leary stated that he started a three months correspondence course at the Swedish College of Massage in Chicago; that he was to pay approximately $30.00 for the course, but had only paid $3.00 and received a half dozen lessons. O'Leary maintained office hours only in the afternoon, devoting the mornings to the sale of aluminum ware. Judge Thompson,

on being fully advised of the facts, sentenced O'Leary to a term of one year in the Clay County jail, suspending the sentence and placing the defendant on probation upon several conditions, the first one being that O'Leary is to refrain from practicing healing in any manner unless he is licensed. The Court, also, ordered O'Leary to pay his personal obligations at Barnesville, Minnesota, on or before March 1, 1939, and to pay the Court costs within 60 days. Judge Thompson, in no uncertain terms, told the defendant that the practice of healing, without being licensed, amounts to swindling and the obtaining of money under a false pretense.

The Minnesota State Board of Medical Examiners wishes to acknowledge the very fine coöperation extended by Mr. James A. Garrity, County Attorney at Moorhead, Minnesota, in the prosecution of this case.

OF GENERAL INTEREST

Dr. E. C. Hanson, formerly of Park Rapids, is now located at Austin, Minnesota.

* * *

Dr. R. H. La Bree of Minneapolis has joined the staff of the Fergus Falls State Hospital.

* * *

Dr. A. B. Rosenfield of Pequot, has been appointed school doctor for the pupils of the Hibbing schools.

* * *

Dr. Arnold Settlage, formerly of Stow, Ohio, has recently become affiliated with the Worthington Clinic.

* * *

Dr. Harry Palmer, formerly of Eveleth, has located at Blackduck, where he is taking over the practice of Dr. D. J. Jacobson.

* * *

Dr. D. W. Cummings, son of the late Dr. D. S. Cummings of Waseca, has returned to Waseca for the practice of medicine, after an absence of several years.

* * *

Dr. C. O. Erickson, formerly on the staff of the Fergus Falls State Hospital, has been appointed Assistant Superintendent of the Rochester State Hospital.

* * *

Dr. D. J. Jacobson, formerly of Blackduck, has located in Bemidji, where he will continue the practice of medicine.

* * *

Dr. James Chessen, of Duluth, has accepted a position at the Washington University postgraduate medical school, in the department of otolaryngology.

* * *

Dr. D. J. Jacobson, formerly of Blackduck, and Dr. W. M. Haller, who has been associated with the Civilian Conservation Corps at Pike Bay, Cass Lake, have opened a suite of offices in Bemidji.

* * *

Dr. Gordon R. Kamman, Saint Paul, opened new offices at 1044 Lowry Medical Arts Building, September 10. Dr. Kamman limits his practice to neurology and psychiatry. His office hours are from two until five.

* * *

Governor E. A. Benson has appointed Dr. John Esser of Perham to the State Board of Health to succeed Dr. S. Z. Kerlan of Aitkin, who has left the state. Dr. A. G. Schulze of Saint Paul has also been appointed to the Board by the Governor to succeed Dr. N. G. Mortensen of Saint Paul.

* * *

Dr. V. E. Quanstrom has returned to Brainerd, where he will be associated with Dr. R. A. Beise. Dr. Quanstrom has recently completed several years of special work and study in surgery under Dr. Alton Achsner at the Tulane University, New Orleans.

After twenty-five years as chief of the Department of Obstetrics and Gynecology at the University of Minnesota, Dr. Jennings C. Litzenberg will complete his active service this month. An appreciation dinner will be held for him at the Minnekahda Club, Minneapolis, at 6 o'clock, Friday evening, October 14, the evening following the Homecoming Game with the University of Michigan. All former students and colleagues of Dr. Litzenberg are invited to attend. Application for tickets may be made to Dr. E. C. Maeder, 732 Eighth Avenue South, Minneapolis.

Silver Anniversary Dinner of the Glen Lake Sanatorium

The growth of Glen Lake Sanatorium, Hennepin County's tuberculosis hospital, from a three-cottage unit of fifty beds to a great, modern institution with facilities for the care of 750 patients, was reviewed at a silver anniversary dinner held at the sanatorium, September 9, honoring the twenty-five years of service of the Glen Lake Sanatorium Commission, its governing board.

E. C. Gale and J. R. Kingman, lay members of the commission, who have served continuously for the past twenty-five years, were guests of honor. Dr. F. H. Harrington, Minneapolis health commissioner, is the third member of the commission. Dr. S. Marx White and the late Dr. John W. Bell preceded him in that office.

The contribution which the sanatorium has made to the sum total of scientific knowledge on tuberculosis was emphasized by Dr. Donald Balfour, Director of the Mayo Foundation.

More than 350 representatives of local and state public health agencies, the medical profession, civic groups and church organizations attended the dinner.

NOTICE

Hereafter all communications to the Minnesota State Medical Association should be addressed to 493 Lowry Medical Arts Building, Saint Paul. Executive offices of the Association have been moved from 11 W. Summit Avenue, Saint Paul, to that address.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR OCTOBER

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 9:45 o'clock every Saturday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month will be as follows:

October 1—Pellagra.

October 8—Visual Errors.

October 15—Influenza.

October 22—How to Gain Weight.

October 29—Loss of Teeth.

THE MINNESOTA MEDICAL ALUMNI ASSOCIATION PROGRAM

From 8:30 to 12:00 on Friday morning, October 14, there will be a program of clinics to be held in Todd Amphitheatre of the University Hospitals, Dr. Harold G. Benjamin, chairman.

Clinics

Dr. Ralph T. Knight, Associate Professor and Director of the Division of Anesthesia.

Dr. Horace Newhart, Professor of Otolaryngology.

Dr. Irvine McQuarrie, Professor of Pediatrics.

Dr. O. H. Wangensteen, Professor of Surgery.

Dr. J. L. McKelvey, Professor of Obstetrics.

Dr. Cecil J. Watson, Associate Professor and Director of the Division of Internal Medicine.

Dr. J. C. McKinley, Professor of Neurology and head of the Department of Medicine.

12:15 to 1:15—Luncheon in the Nurses' Hall at the weekly hospital staff meeting by courtesy of Mr. Ray Amberg, Superintendent of the Hospital.

1:15—Annual business meeting, Dr. Robert L. Wilder, President.

Additional Activities of the Homecoming Weekend

Appreciation dinner for Dr. J. C. Litzenberg, the retiring chief of the Department of Obstetrics, at the Minikahda Club at 6:00 p. m., Friday, October 14.

Following the homecoming game, Saturday, between Minnesota and Michigan, there will be a tea in the Nurses' Hall with dancing and refreshments. This event is sponsored by the nurses, who are inviting the attendance of student and graduate nurses, doctors, dentists, dental hygienists and medical technicians.

WOMAN'S AUXILIARY

Mrs. W. B. Roberts, President
2735 Irving Avenue South, Minneapolis.
Mrs. E. V. Goltz, Press and Publicity, St. Paul, Minn.

THE sixteenth annual convention of the Women's Auxiliary to the Minnesota State Medical Association was held in Duluth, June 29, 30, and July 1, with Mrs. J. F. Norman of Crookston, president, presiding. Registration at the Hotel Duluth, Wednesday, June 29, followed by the Executive Board meeting at 10:30 in the Royal Room of the Chamber of Commerce, opened the session. In the afternoon a delightful tea was given in honor of the visitors at the Woman's Club and the same evening a Public Health meeting was held in the Orpheum theater. Thursday morning at 10 o'clock the annual meeting of the Auxiliary was held at the Northland Country Club at which Mrs. M. G. Gillespie, president of the St. Louis County Auxiliary, gave the address of welcome with Mrs. C. L. Oppegaard of Crookston, responding. A memorial service was given by Mrs. W. W. Moir of Minneapolis. Reports from the various chairmen and county presidents were read and the meeting closed with the election of officers. A luncheon followed at the Northland Country Club, and members heard Dr. Howard W. Haggard, Associate Professor of Applied Physiology, Sheffield Scientific School, Yale University, speak on "The Social Side of Medical Progress." Newly elected officers were presented and the Auxiliary members were greeted by the newly elected president, Mrs. W. B. Roberts of Minneapolis. A post-convention Board meeting followed. The annual banquet was held at the Hotel Duluth at 6:30 that evening with Dr. J. M. Hayes, president of the Minnesota State Medical Association, as the toastmaster. Mrs. W. B. Roberts, the newly elected president of the Woman's Auxiliary, was presented and greetings were extended by Dr. Irvin Abell of Louisville, president of the American Medical Association, and an address by Dr. Howard W. Haggard. Dancing followed. Owing to the weather conditions the delightfully planned trip on Lake Superior had to be cancelled but a group of women enjoyed having luncheon on board the boat. The warm friendship and hospitality of the members of St. Louis County Auxiliary made up entirely for the lack of sunshine and pleasant weather conditions.

The following appointments have been made by the newly elected president, Mrs. W. B. Roberts. The medical advisory council will include Dr. J. M. Hayes and Dr. C. B. Wright of Minneapolis and Dr. W. A. Coventry, of Duluth. The advisory committee of the Auxiliary is composed of Mrs. Charles W. Mayo, Rochester; Mrs. A. A. Passer, Olivia; Mrs. Benjamin Davis, Duluth, and Mrs. Charles Bolsta, Ortonville. Mrs. W. W. Moir of Minneapolis has been appointed corresponding secretary and Mrs. M. S. Hirschfield of Duluth parliamentarian. Mrs. J. A. Thabes of Brainerd is historian. The committee chairmen chosen from various parts of the state are: Legislative, Mrs. E. A. Eberlin of Glenwood; Finance, Mrs. James Blake

of Hopkins; Public Relations, Mrs. A. F. Branton, Willmar; Hygeia, Mrs. W. W. Will, Bertha; Health Education, Mrs. H. E. Wunder, Shakopee; Press and Publicity, Mrs. E. V. Goltz, St. Paul; Exhibits, Mrs. Harrold Wahlquist, Minneapolis; Archives, Mrs. S. S. Hesselgrave, St. Paul; Printing, Mrs. Frederick Erb, Minneapolis, and Revisions, Mrs. E. C. Eshelby, St. Paul.

Members of the Social Committee are: Mrs. Martin Nordland, Minneapolis; Mrs. E. M. Hammes, Saint Paul; Mrs. F. J. Elias, Duluth; Mrs. F. A. Figi, Rochester.

Elective members of the Executive Board include: Mrs. A. C. Baker, Fergus Falls, president elect; Mrs. John F. Norman, Crookston, past president; Mrs. Malcolm Gillespie, Duluth, first vice president; Mrs. J. J. Ryan, Saint Paul, second vice president; Mrs. G. E. Hertel, Austin, third vice president; Mrs. George Earl, Saint Paul, fourth vice president; Mrs. R. J. Josewski, Stillwater, recording secretary; Mrs. Russell Noice, Minneapolis, treasurer, and Mrs. T. M. Fleming, St. Cloud, auditor.

Mrs. Roberts asked the members to pursue definite health projects in the coming year and to fulfill the Auxiliary's dual purpose of assisting the State Medical Association and the county auxiliaries. She stated that the scope of the Auxiliary's service had widened from the original function of promoting fellowship and mutual understanding within the medical profession to include, now, an effort to create better understanding among lay groups of what the medical profession is trying to do for public welfare.

At the request of the Minnesota Medical Association, the Auxiliary will give special attention this year to the need for immunization against communicable diseases. The Auxiliary will continue its support of the campaign to control cancer and the fight against tuberculosis. Members are urged to undertake, in their everyday contacts, to spread the gospel of regular and thorough physical examinations by competent physicians as a preventative measure. Mrs. Roberts recommended popularizing legitimate and reliable health magazines, such as *Hygeia,* published by the American Medical Association, and *Everybody's Health,* issued by the Minnesota Public Health Association. As a special project, she suggested that the Auxiliary sponsor or stimulate interest in the showing of health motion pictures. "Any legitimate and ethical means at our command should not be overlooked to emphasize the unselfish and willing devotion of the honest medical practitioner to a suffering world."

BE PREPARED!!

Pneumonia Season Is HERE!

An ample supply of Lederle Antipneumococcic Serum should be on hand for early treatment of Pneumonia types I and II. For treatment, supplied in following packages:

10,000 units in Syringe..$ 6.60

20,000 units in Syringe.. 11.33

For Typing: (Types I to XXXII)

Supplied in 5 capillary tubes
Five tubes.....$ .50

For EMERGENCY, call Brown & Day at any time. Oxygen Tent rental service, as well as . . .

MINNESOTA STATE MEDICAL ASSOCIATION

Eighty-Fifth Annual Meeting

June 28, 29, 30 and July 1, 1938

Duluth, Minnesota

HOUSE OF DELEGATES

First Meeting
Tuesday Afternoon, June 28, 1938

THE first session was called to order by Dr. W. W. Will, Bertha, speaker of the house, at 3:30 p. m., Tuesday, June 28.

Following brief greetings from Dr. Irvin Abell of Louisville, Kentucky, president of the American Medical Association, and a report from Dr. F. J. Lexa, Lonsdale, chairman of the Committee on Credentials, showing a quorum of members to be present, Reference Committees were appointed and committee reports assigned to them as follows by the speaker:

Scientific Reference Committees

Medical Education Reports

A. E. Cardle.....Minneapolis
(Appointed to act as Chairman in place of Dr. C. J. Ehrenberg, who was absent because of illness)
J. R. Aurelius.....St. Paul
P. J. Hiniker.....Le Sueur
H. A. Roust.....Montevideo

Miscellaneous Scientific Reports

C. L. Roholt.....Waverly
P. M. Gamble.....Albert Lea
F. H. Magney.....Duluth
C. O. Maland.....Minneapolis
C. A. McKinlay.....Minneapolis

Non-Scientific Reference Committees

Credentials Committee

F. J. Lexa.....Lonsdale
B. A. McIver.....Lowry
E. A. Thayer.....Truman

Lay Education Reports

F. J. Elias.....Duluth
(Appointed to act as Chairman in place of Dr. J. W. Helland, who was absent)
H. C. Cooney.....Princeton
B. A. Smith.....Crosby
E. J. Wohlrabe.....Springfield

Medical Economics Reports

M. C. Piper.....Rochester
G. I. Badeaux.....Brainerd
H. W. Goehrs.....St. Cloud
J. C. Jacobs.....Willmar
A. G. Liedloff.....Mankato

Officers and Council Reports

S. A. Slater.....Worthington
E. S. Boleyn.....Stillwater
W. F. Braasch.....Rochester
A. J. Lewis.....Henning
J. F. Norman.....Crookston

State Health Relations Reports

A. H. Zachman.....Melrose
O. W. Holcomb.....St. Paul
R. H. Wilson.....Winona

By motion duly seconded and carried, reading of the minutes of the last meeting of the House of Delegates was dispensed with and the meeting was recessed at 3:40 p. m. to permit the Reference Committees to consider and prepare their reports on the committee reports submitted to them.

The meeting was re-convened at 7:55 p. m. by Speaker W. W. Will.

DR. WILL: I think we are all in full agreement that the House of Delegates wields a most far-reaching influence in our state. As I look over the group before me I see many who have been active in the affairs of our Association in the past and I am encouraged to believe that all have been elected because of a keen interest in the welfare of organized medicine. I hope that all of you will make detailed reports of the business that is transacted here at the first meeting of your respective societies. I hope, also, that all of you will feel free to take an active part in the discussions and to make any criticism or suggestion that may occur to you, both as to the business under discussion and as to the conduct of the meeting. One of our councilors remarked to me today that he was surprised at the valuable suggestions offered by delegates at a preliminary group meeting in his district. If it is timidity that prevents the delegates from offering suggestions here, may I ask you gentlemen not to be timid. This is your meeting; it will be your fault if our discussion tonight does not cover the things in which you as delegates are interested.

Following a report by Doctor Lexa, chairman of the Committee on Credentials, which was accepted by the House and which showed that a quorum of members was present, Speaker Will called upon Dr. George Earl of St. Paul, Chairman of the Council, for a report of the day's Council meetings.

Doctor Earl reported as follows and his report was accepted by the delegates:

REPORT OF THE COUNCIL

Three hospital or medical service plans on the prepayment basis were discussed and motions that we secure more information about them were duly passed. They included the American Benefit Association plan, a plan offered by a commercial insurance company; the Hawaii Medical Service Association, sponsored by a group of laymen and some doctors acting as individuals; the Toronto Medical Society plan sponsored, as indicated, by the medical society of Toronto.

An estimate was submitted by R. R. Rosell, executive secretary of the Association, showing that this Annual Meeting will undoubtedly pay for itself and that it will be unnecessary to draw upon the fund of $1,500 allotted in the budget to Annual Meeting expense. An increase of 95 members over last year was also reported by Mr. Rosell.

The Minnesota Social Hygiene Institute of Minneapolis, likewise reported upon by Mr. Rosell, was thoroughly investigated by Dr. A. J. Chesley, executive officer and secretary of the Minnesota Department of Health and found to be a lay organization without qualified medical advice or sponsorship, organized with-

out consulting any of the constituted health authorities for the purpose of public health education on venereal disease. The Council directed that an article on the subject be prepared with the approval of Mr. F. Manley Brist, attorney for the Association, and printed in MINNESOTA MEDICINE.†

It was agreed that copies of the 1938 Roster should be sent as usual to judges of the district courts and of the probate courts of Minnesota for their information and assistance.

It was suggested that members of the Council keep in touch with members of the State Legislature and also with Minnesota members of the House and Senate in Washington. They were urged to express their feeling about current policies that concern medicine or public health, to keep legislators informed about the policy of organized medicine on all these matters and particularly to express their appreciation for the efforts of these legislators to safeguard American medicine and protect the public health.

It was agreed by the Council that the fiscal agency account as reported upon by the Finance Committee is in excellent shape and that the financial condition of the Association as reported upon by the treasurer has been also entirely satisfactory so far this year.

The Council approved the organization of a club to be called "The Fifty Club" and to be made up entirely of members who have been licensed to practice fifty years in Minnesota. These members will be honored as a group by the Association in general on appropriate occasions.

The Council also voted a letter of thanks to be sent to Dr. J. T. Christison and Dr. W. F. Wilson for their gift to the Association of old copies of MINNESOTA MEDICINE and of the *St. Paul Medical Journal* so that files of Association publications might be complete in our state headquarters.

It was decided unanimously that a distinguished service award should be presented on occasion to members of the Association whose contribution to the work of the Association merits such recognition. The following resolution accompanied this action:

"RESOLVED that the Minnesota State Medical Association should provide an appropriate token to be awarded on occasion to members of the Association who have rendered special, valuable and distinguished service to the Association; also, that selection of candidates for this award be left in the hands of the Council."

Other resolutions passed by the Council which are of special interest to the delegates are quoted herewith:

"WHEREAS, the Finance Committee of the Minnesota State Medical Association have carefully investigated the books and records of the Minnesota State Medical Association with the assistance and advice of their auditor, Mr. Byers, and found all entries on the books and records of said Association to be true, correct and proper, and

"WHEREAS, the 'inventories' submitted by the Chairman of the Council have been fully explained and discussed with Mr. Byers, auditor, and it is understood that the items of furniture on this list are in the possession of the Minnesota State Medical Association and that the equipment has been fully accounted for, and

"WHEREAS, all trade contracts have been individually investigated and have been found without exception to be to the financial advantage of the Association, therefore be it

"RESOLVED, that our secretary, E. A. Meyerding, M.D., be highly commended for the manner in which he has handled all Association affairs, and be it further

"RESOLVED, that an expression of appreciation be extended to Doctor Meyerding for the efficient and competent service he has given the Minnesota State Medical Association, and that he be asked to extend this appreciation of the Minnesota State Medical Association to his office staff and business associates for their assistance."

* * *

"WHEREAS, the Finance Committee of the Minnesota State Medical Association has thoroughly investigated the costs of the publication of MINNESOTA MEDICINE by the Bruce Publishing Company, and has also obtained independent estimates on printing and office editorial work, and

"WHEREAS, they have found that the present costs are in no way excessive, although certain suggestions for economies may be suggested by the Editing and Publishing Committee, be it

"RESOLVED, that the Council of the Minnesota State Medical Association extend to the Editing and Publishing Committee and to the Bruce Publishing Company their sincere commendation and also their gratitude for the services rendered in such a faithful manner over these many years in developing and producing a journal of exceptional merit."

It was suggested that the earlier action of the House of Delegates, setting apart the Herman M. Johnson Memorial Fund in perpetuity for a lectureship which should appropriately commemorate the work of the late Doctor Johnson and directing that only the income from the fund be used for the purpose, be recalled and re-emphasized at this meeting.

The committee reports, designated under the general title "Medical Education Reports" and reviewed by the Scientific Reference Committee under the chairmanship of Dr. A. E. Cardle of Minneapolis follow:

COMMITTEE ON CANCER

The Committee on Cancer and the Council of the Minnesota State Medical Association have extended their coöperation to the Women's Field Army of the American Society for the Control of Cancer as a means of educating the public in the prevention and cure of cancer.

As part of this coöperation a specimen talk for use of physicians in addressing lay audiences on the subject of cancer was prepared by the committee and sent to every member of the Association with a letter from the committee setting forth its relationship and that of the Council to the Women's Field Army.

It was agreed that county and district medical societies should be requested to coöperate in the educational campaign of the Women's Field Army, also the Women's Auxiliary and that the Councilor in each district should be chief advisor as to plans and policies.

It was also decided that a Speakers' Bureau to be used by the Field Army should be on file at the State Office and that county medical societies in each instance should be consulted as to whether the speaker chosen is satisfactory to them.

It was determined by the Council, meeting with the Committee on Cancer, that the executive committee of the Women's Field Army should consist of the chairman of the Committee on Cancer, the State Commander of the Women's Field Army, the president-elect and secretary of the Minnesota State Medical Association, the state chairman of the American Society for the Control of Cancer, the state treasurer of the Women's Field Army, the chairman of the Committee on Public Health Education of the State Medical Association and representatives of the Field Army, which should be selected by the women's organization and approved by the Committee on Cancer and the Executive Committee as originally constituted. This committee held its first meeting in June, 1938.

Two state-wide cancer meetings under the auspices of the Women's Field Army were held during the year.

One was held in Minneapolis, December 8, with Mrs. Marjorie B. Illig of New York, national commander of the women's organization and Dr. F. L. Rector of

†The article appeared on page 584 of the August, 1938, issue.

Evanston, field representative of the American Society for the Control of Cancer, as guest speakers.

The other was held on the University of Minnesota campus with Dr. C. C. Little, managing director of the American Cancer Society, as principal speaker.

MARTIN NORDLAND, *Chairman*

The Reference Committee recommended acceptance of the report, recorded its appreciation of the interest and coöperation of the Women's Field Army and urged that all members of the Association make use of material available at the State Office to extend cancer education and coöperate with their local committees which are working on the cancer problem. The report was accepted.

COMMITTEE ON DIABETES

Revision of the booklet "Diabetes, How to Make It Harmless" was discussed at a meeting of the committee, June 4, and delayed by decision of the committee because treatment is in a state of flux at present. Members will study revision during the coming year. They propose, also, to draw up a series of short paragraphs for lay education on control and treatment of diabetes; to ask approval of the delegates for an effort to obtain a dietitian or nurse dietitian to be paid out of relief funds for the education of diabetic relief clients; to attempt to determine the attitude of industry toward diabetics and their employment.

H. B. SWEETSER, JR., *Chairman*

The Reference Committee recommended acceptance of the report, suggested that the problem of obtaining help for the education of relief clients is a local problem and should be handled locally, and agreed with the committee that the medical profession should stand ready to help both employer and employe to solve the diabetes problem as it relates to industry. It was further noted that the diabetes booklet in its present form is valuable and should be distributed continuously while the process of revision is carried on. The suggestion was made, however, that the term "harmless" be avoided in the title of the revised publication. The report and suggestions of the Reference Committee were accepted by the delegates.

COMMITTEE ON SYPHILIS AND SOCIAL DISEASES

The work of the Committee on Syphilis and Social Diseases is largely advisory at present since there seems to be no need, currently, to expand the venereal disease program of the State Board of Health in Minnesota; furthermore, no funds are available for any additional program.

The program of the State Board of Health has been well established for many years and has the approval of the Committee. At the suggestion of representatives of the American Social Hygiene Association, a special educational campaign has been carried on jointly in two or three localities of the state by the Junior Chamber of Commerce and the local medical society. The campaign carried on in Saint Paul by the Ramsey County Medical Society and the Junior Chamber of Saint Paul was notably successful.

Current public interest in the control of venereal disease has been utilized by fakers and commercial organizations, among the latter being the Minnesota Social Hygiene Institute, which proved, upon investigation, to have no qualified medical backing. Every effort should be made to eliminate unnecessary and unauthorized undertakings of this sort.

S. E. SWEITZER, *Chairman*

The Reference Committee approved the report, commending the committee for its work, and the delegates accepted it. The hope was expressed that the committee would continue the work of investigating non-medical organizations that might in the future attempt to exploit the program of venereal disease control.

Dr. T. H. Sweetser, chairman of the Committee on State Health Relations, said from the floor that the State Board of Health, from whose meeting he had just come, would consider the venereal disease program the next morning in the light of the new legislation on the matter just passed by Congress. The Board had expressed itself as anxious to have members of the Committee on Syphilis and Social Diseases present at the morning meeting so that they might have the opinion of the committee as well as of the Council, which had also been invited to attend. Members of the Board also suggested, according to Doctor Sweetser, that the House of Delegates might wish to make some official statement, concerning lay associations that are collecting money, ostensibly to further the venereal disease program but actually for commercial purposes.

The speaker recommended that the Committee on Syphilis and Social Diseases attend the State Board of Health meeting and make whatever recommendations to the House that they should see fit.

COMMITTEE ON DEAFNESS PREVENTION AND AMELIORATION

Activities of the Committee on Deafness Prevention and Amelioration during the past year have included exhibits at the state meeting of 1937 in Saint Paul and at the Minnesota State Fair in September of the same year. Also demonstration hearing surveys in several colleges and communities, in connection usually, with public health or parent-teacher meetings. The committee also worked for passage of a bill to provide means for a more adequate public health program including hearing testing in the schools. The bill failed of passage but much interest was created in the problem, particularly of hard-of-hearing children in the schools.

Increasing interest in acquirement of modern equipment for testing hearing on the part of schools has been demonstrated in the past year. In the opinion of the committee every community having a school population of 2,000 or more should own its own equipment for testing hearing. The need is especially urgent in rural districts.

The work of the committee should be continued and a reasonable grant made to carry out its activities.

HORACE NEWHART, *Chairman*

The Reference Committee approved the report, commending the committee for its work, recommended acceptance of the report and appropriation of the grant requested for continuance of the work. It was suggested that any information in the possession of the committee on mechanical devices for testing the hearing and also for the aid of the hard-of-hearing be placed at the disposal of the profession. The report was accepted.

Doctor Newhart emphasized in a supplemental discussion of his report the need for additional funds. He emphasized, also, the need to rouse local interest in each community in the work of the committee. It is the hope of the committee that a state-wide program

can be established within the next few months; but it cannot be done without the active aid and leadership in each locality of members of the profession. The cooperation of the delegates was earnestly invited.

COMMITTEE ON MATERNAL AND CHILD WELFARE

With the collaboration of the Committee on Maternal Welfare and the Committee on Hospitals and Medical Education of the State Association, also of the University of Minnesota, the Minnesota Department of Health conducted the first series of postgraduate courses, so-called "refresher courses," in obstetrics and pediatrics in the state in May and June of 1937. These courses were sufficiently successful to warrant similar courses this year but with the difference that the 1938 courses were all given on one day instead of a weekly intervals. In 1937 the courses were given in Worthington, Brainerd, St. Cloud, Fergus Falls, Grand Rapids and Mankato. In 1938 they were given in Crookston, Winona, Hibbing, Willmar, Albert Lea, Fergus Falls, Worthington and Bemidji. The total attendance in 1937 was 1,005, a weekly average of 167½. Complete attendance reports have not been obtained as yet for this year's courses, but the indications are that the course was well received.

The newly organized State Society of Obstetrics and Gynecology held its last semi-annual meeting in St. Paul in April. Largely as a result of the efforts of this society the Central Association of Obstetricians and Gynecologists will hold its annual three-day meeting in Minneapolis next October, a further evidence of the growing interest in maternal welfare in Minnesota.

Maternal mortality rate for 1937 in Minnesota was 3.0 per 1,000 live births and the infant rate was 40.8. This is by far the lowest rate reported by any state in the United States.

R. D. Mussey, *Chairman*

The Reference Committee commended the work of the committee, endorsed the postgraduate lecture courses and recommended their continuance and the acceptance of the report by the delegates. The report was accepted.

The committee reports designated as "Miscellaneous Scientific Reports" and reviewed by the Scientific Reference Committee under the chairmanship of Dr. C. L. Roholt of Waverly, follow:

COMMITTEE ON HOSPITALS AND MEDICAL EDUCATION

The new experiment in postgraduate medical education, now in its second year at the Center for Continuation Study, University of Minnesota, under the direction of Dr. W. A. O'Brien, also, the postgraduate courses in obstetrics and pediatrics carried on in key communities throughout the state under the direction of the Division of Child Hygiene of the State Board of Health, are new centers of activity in this type of education.

This committee and the State Office have assisted in both programs. The committee also consulted with Dr. Hamilton H. Anderson of the Council on Medical Education and Hospitals, American Medical Association, concerning a survey of postgraduate education in Minnesota which later was made in coöperation with the State Office. A résumé of this survey was printed in the *Journal of the American Medical Association*, March 5, 1938, page 136B.

It seems obvious that the postgraduate courses sponsored and financed solely by the State Association are not now needed in Minnesota.

James B. Carey, *Chairman*

The Reference Committee recommended acceptance of the report with the following substitution for the final paragraph of the report:

"It appears to the committee to be too early to state that postgraduate courses sponsored and financed solely by the state association are not needed."

The delegates accepted the report with the change recommended.

SUB-COMMITTEE ON PUBLIC HEALTH NURSING

In conjunction with a representative of the Public Health Nursing Department, a set of Orders and Policies to guide nurses employed in boys' and girls' summer camps was formulated and copies sent to the members of this committee for their suggestions and approval. All committee members heard from approved, and mimeographed copies of the subject matter will be sent to nurses so employed.

H. F. Bayard, *Chairman*

In compliance with the recommendation of the Reference Committee the delegates accepted the report.

COMMITTEE ON MILITARY AFFAIRS

The current status of Medical Reserves in Minnesota may be detailed as follows: For the Army—6 Colonels, 13 Lieutenant Colonels, 12 Majors, 48 Captains, 304 First Lieutenants. For the Navy—24 Lieutenant Commanders, 12 Lieutenants and 3 Lieutenants, Junior grade.

The profession is to be commended for careful examination of C. M. T. C. applicants. Medical Reserve Officers who are designated by the Chief of Staff of the First Reserve Area to serve on Boards for Appointment and Promotion are urged to adhere to regulations strictly so that personnel in the Reserve Corps may be of the type desired for service in the Army.

The ninth successive Medico-Military Inactive Duty Training Course of the Mayo Foundation was held this year at Rochester with 32 states represented and a total of 1,164 enrolled during the past nine years for the course. Several other medical centers throughout the country have also instituted courses recently. They are patterned after the original "Skinner Plan" employed since 1929 by the Mayo Foundation.

Funds allotted by War Department to the Surgeon General have been inadequate for training of medical reserve officers ordered to Flight Surgeon's School for practical training. Also, the War Department ruling grounding all but five of the 285 flight surgeons in the regular army, national guards and reserves, will handicap the aviation medical service, in the opinion of the committee, since pilots should be observed under flying conditions as well as on the ground. Every effort should be made to have this ruling annulled.

Reserve officers should avail themselves of all opportunities to participate in army maneuvers, since much can be learned when serving with the troops in the way of organization, instruction, sanitation and many other details that cannot be learned from books. Medical officers participating in the Fourth Army Maneuvers at Fort Ripley last August acquitted themselves creditably. In the four concentrations of the army there were 1,803 reserves, of whom 16 per cent were in the medical department, ordered to active duty.

Twenty-six medical reserve officers are on CCC duty in Minnesota at the present time. A number of officers on CCC duty have successfully passed army examinations and have entered the regular establishment for their professional careers.

Re-establishment of the medical R. O. T. C. on a voluntary basis at the University has resulted in an en-

rollment that is far below the enrollment when the training was compulsory. Only 17 medical students enrolled for the training last fall, with 16 for the winter quarter and 13 for the spring quarter. This training should be established on a compulsory basis in order to qualify students for leadership in any branch of the service of the United States in time of emergency.

The bill for amending the National Defense Act to provide uniforms and other allowances to the officers of the Reserve Corps is noted by the committee. It provides for an allowance for each hour of credit earned in Army Extension Courses by members of the Officers' Reserve Corps who are eligible for active duty in excess of the annual minimum of 20 and not to exceed $75 in one year, as well as allowance for uniforms.

Attention of all Reserve Corps officers in the association is called to the Annual Convention of the Association of Military Surgeons to be held at Rochester, October 13, 14 and 15.

Lt. Col. F. L. Smith, *Chairman*

In compliance with the recommendation of the Reference Committee the report was accepted by the delegates.

HISTORICAL COMMITTEE

Two more county histories and several other manuscripts of historical interest have been received by the committee during the past year.

Installments of the "History of Medicine in Minnesota" have appeared regularly since January, 1938, in Minnesota Medicine, and sufficient material is on hand to continue the installments for at least two years.

Criticisms and correction of the published material are invited so that, should the history later be published in book form, they may be incorporated in an appendix.

The committee will continue to gather data and hopes to receive additional manuscripts from individual members of the Association. It also wishes to thank the Council for its coöperation and support, which have made possible publication of the material.

J. M. Armstrong, *Chairman*

Complying with the recommendation of the Reference Committee, the report was accepted by the delegates.

COMMITTEE ON FRACTURES

A definite fracture program for Minnesota is suggested by the committee to include the following:

I. Creation of a permanent State Fracture Committee to consist of a chairman, appointed by the president and one member from each constituent society.

II. Formation in each constituent society of a fracture committee which should have its representative on the state committee for chairman and which should draw up a definite fracture program for the society, including an annual fracture symposium to be held at one of the regular society meetings.

III. Adoption of the following statewide program to be carried out by the state committee in coöperation with the constituent societies:

A. *First Aid and Transportation.*

1. Adoption throughout the state of the Keller-Blake hinged, half-ring splint for the lower extremity, and the Murray-Jones hinged ring splint for the upper extremity, these splints to be of the size and specifications used by the United States Army.

2. Education of profession and public in use of the splints.

3. Equipment of ambulances throughout the state with these splints; also industrial plants. Hospitals should be equipped likewise for the purpose of exchange with ambulances when patients are brought in with the splints on, since the splints cannot be removed for some time and the ambulance must be on its way.

4. Coöperation with the Red Cross in its First Aid Station work throughout the state (splints are now available at these stations), with the Highway Department and the Boy and Girl Scouts in their First Aid educational program.

B. *Diagnosis.*

1. Adoption of standardized surgical directions to insure proper films and promotion of frequent x-rays to determine reduction and progress of healing.

C. *Hospital Equipment.*

1. For treatment of fractures of the long bones all hospitals should have overhead frames for suspension and traction, simple splints, Thomas arm and leg splints, equipment for skeletal traction; a portable x-ray apparatus.

D. *Treatment.*

1. Liberal constructive discussions should be allowed at society and hospital staff meetings.

It is further suggested by the committee that every annual meeting program should include a fracture symposium and that an exhibit showing first aid in transportation, x-ray diagnosis, hospital equipment, treatment, et cetera, should be arranged by the committee for each meeting.

O. W. Yoerg, *Chairman*

The suggestion of a permanent state fracture committee was especially commended by the Reference Committee and, complying with its recommendation, the report was accepted by the delegates.

COMMITTEE ON ASPHYXIA AND ASPHYXIAL DEATH

The increasing use of automobiles and of gas in the home has increased both morbidity and mortality from asphyxia and the committee notes a growing need for the medical profession to give special thought to the subject.

Carbon monoxide is the chief source of poisoning. Most common causes are illuminating gas, exhaust gas from internal combustion motors and coal gas from defective furnaces or stoves.

One thousand asphyxia deaths are estimated to occur weekly in the United States, of which 50 per cent are due to carbon monoxide inhalation, either accidental, suicidal or homicidal. The interiors of about 5 per cent of automobiles on the highways have been found to contain a sufficiently high concentration of carbon monoxide to produce such symptoms as dizziness or collapse. The blood of about 49 per cent of 426 garage employes studied recently was found positive for carbon monoxide, the percentage in the blood of the positive reactors ranging from 5 to 30 per cent.

Recognition of chronic poisoning which develops insidiously due to repeated exposure to sublethal concentrations of gas over a long period of time is important, as well as recognition of acute poisoning. Much still remains to be learned about the subject, but it has entered today into the domain of everyday practice, and the committee hopes to make studies, formulate plans for public education on the subject which may in time serve to reduce the incidence of asphyxia and asphyxial death.

A. E. Cardle, *Chairman*

Stressing the importance of further study in this field and the need for funds to carry out such work, the Reference Committee recommended acceptance of the report. The report was acceptd.

Committee reports designated "Lay Education Reports" and reviewed by the Non-Scientific Reference Committee under the chairmanship of Dr. F. J. Elias

of Duluth acting for Dr. J. W. Helland of Spring Grove, follow:

COMMITTEE ON PUBLIC HEALTH EDUCATION

There is good reason to believe that public health education is the greatest problem that faces the doctor today. When the neglected illness is thoroughly investigated, it usually develops that ignorance or carelessness and not actual lack of medical facilities was the cause of the neglect. The conclusion is inescapable that public health education is fundamental to the solution of the medical problem of this country rather than subsidies to physicians, new laws or new taxes.

It becomes increasingly clear to members of this committee, furthermore, that it is the doctors and not the nurses, social workers or lay health agencies who must direct the educational work.

The Committee on Public Health Education carries on certain state-wide activities which can best be handled from state headquarters. These activities have expanded but will not be truly effective until every individual member is supplementing them by his own efforts in his own community—by initiative in bringing preventive measures to his people, by working intelligently with local health and welfare agencies, and by individual instruction which will bring the people in his community to the doctor promptly, whether or not they are able to pay full fees for his services.

If the patient's income is not sufficient to pay full private fees then the doctor himself must know all of the facilities of the community and state in order to utilize the aid of welfare and relief agencies efficiently for his patient.

Where improvements are needed the doctor must be the first to work intelligently and conscientiously with the responsible officials to improve the situation.

Certainly it is illogical and unjustifiable to embark upon radical and expensive legislative changes until our established agencies have had a chance to show their effectiveness for all the people.

Committee activities for 1937-1938 include the following:

1. The *News Service* prepared under the auspices of the editorial subcommittee which goes weekly to all newspapers in Minnesota, designed especially to provide health instruction and instruction on disease prevention.

2. *Speakers' Bureau* made up of a list of capable speakers from all parts of the state on file at the State Office and available for talks on health and preventive medicine before lay groups of all kinds.

3. *College Lecture Course* designed to reach young men and women in the colleges, who will be the teachers and professional men and women of the future. A series of four or five talks given annually in the majority of the colleges of the state, honorariums and traveling expenses of speakers paid by the Minnesota State Medical Association, arrangements and booking made by the Minnesota Public Health Association.

4. *Speakers' Library,* a file of material maintained at the State Office for use of speakers who are requested to make public health talks before lay audiences.

5. *Hygeia, Everybody's Health.* After a lapse of several years *Hygeia* is now being sent to the members of the State Legislature by order of the Council. Through a special arrangement with the Minnesota Public Health Association, *Everybody's Health* will go with it at a special rate secured for both publications.

6. *4-H Club.*—Annual physical examinations of county contestants for state honors among 4-H Club members in Minnesota. More than 200 boys and girls were examined in 1937 by a group of 11 specialists. Physicians' time is compensated out of the budget of this committee. Arrangements are made by the Minnesota Public Health Association, which also contributes use of its headquarters.

7. *Literature.*—A folder called "Your Child's Health," which was prepared under the supervision of the Editorial subcommittee, was distributed widely in the state this year in coöperation with the Minnesota Public Health Association.

Attention of the members is called especially to the large number of agencies and campaigns independent of Organized Medicine that are now directing their attention to public health education and promotions. In general, these agencies have enlisted the advice and assistance of the State Association. They have great potentialities for good but only if sponsored and directed by physicians. Chief among them are: The Women's Field Army of the American Society for the Control of Cancer; the Syphilis and Venereal Disease campaign sponsored nationally by the United States Public Health Service and the American Social Hygiene Association; the Pneumonia campaign, a campaign for universal typing of pneumonia cases and use of serum for appropriate cases sponsored by large insurance companies and health agencies everywhere and locally by the Minnesota State Department of Health; the Maternal and Child Health program sponsored nationally by the Committee on Maternity and Child Health and materially assisted by new programs financed by Social Security funds—the film "Birth of a Baby," departure in education by motion picture, marked the campaign this year; the Diabetes control campaign, sponsored by a special society in New York fostered in Minnesota by the State Association.

The practicing physician must be thoroughly informed on the objectives and accomplishments of all of these campaigns and programs. Beyond all this, he must be an apostle in his own community to extend information concerning all medical services and all accepted preventive measures. Much is demanded of him, but much will be lost, also, to himself and to the public he serves if he fails to assume this obligation.

L. R. Critchfield, *Chairman*

SUB-COMMITTEE ON RADIO

Considerable interest has been shown by county medical societies during the past year in the possibility of establishing radio programs in addition to the state association sponsored broadcasts of Dr. W. A. O'Brien from WCCO. In accordance with an action of the Council the committee has encouraged this interest and assisted in obtaining broadcasting material. Arrangements are now under way looking to the possibility of extending Doctor O'Brien's broadcasts by special wire to station KDAL in Duluth.

From May 8, 1937, to June 11, 1938, inclusive, this committee sponsored 42 radio talks by Doctor O'Brien over WCCO in Minneapolis. In addition, there were joint broadcasts on the last Saturday of each month with the Minnesota State Dental Association, amounting to 12 in all. The speaker was Dr. W. A. O'Brien, Associate Professor of Pathology, Preventive Medicine and Public Health of the University of Minnesota. As in the past, the radio station made no charge for the use of its facilities.

The subjects for the period included:

Child Health Day, Some Major Health Problems, Nervous Exhaustion, Avitaminosis, Water Cures, Diverticulitis, Fourth of July Injuries, Dysentery, Pre-School Examinations, Coronary Occlusion, Sore Throat, Diphtheria and Smallpox, Duodenal Ulcer, Insomnia, Heart Disease, Hand Infections, Dietary Dangers, Acute Abdominal Conditions, Diabetes Mellitus, Emotional Stability, Tuberculosis, Nasal Obstruction, Typhoid Fever, Public Health Objectives, Pneumonia Types, Measles Prevention, Early Tuberculosis, Infant Feeding, Scarlet Fever, Asthma in Children, Acute and Chronic Alcoholism, Geriatrics, Communicable Disease Control, Early Diagnosis Campaign, Glaucoma, Brain Tumors, Periodic Health Examinations, Air and Sun, Research and the Hospital, Chronic Illness, and Burns.

On April 2 the committee also sponsored a special broadcast commemorating the tenth anniversary of this radio health education series. Speakers at the regular broadcasting period in the morning were Dr. J. M. Hayes, president of the State Association, Mr. Max Karl, Director of Education of WCCO, and Dr. Robert Burns, chairman of the sub-committee on Radio, together with Doctor O'Brien. At noon representatives of the medical organization, civic organizations, the state dental association, the radio stations, the University of Minnesota and the press were invited to a luncheon to commemorate the event. The Minnesota State Medical Association enjoys the distinction of sponsoring the oldest local broadcast except the market report to be given from Station WCCO. More than 500 talks have been given by Doctor O'Brien, and the program continues to have excellent following. In spite of the fact that there is no attempt to solicit mail, there is a regular flow of questions from listeners. In addition, Doctor O'Brien receives numerous requests to speak in person before all manner of organizations, also to participate in broadcasts sponsored by other organizations and agencies.

The Committee desires to thank Station WCCO for its unfailing courtesy and coöperation and its sincere effort to maintain a definite place on the air for the program. The time, 9:45 a. m. Saturday, has been occupied continuously for many months.

R. M. Burns, *Chairman*

SUB-COMMITTEE ON SPEAKERS' BUREAU

Speakers and materials have been supplied to all organizations that have requested the service. As far as possible speakers have been chosen from within the neighborhood from which the request came for obvious reasons of economy, though it is occasionally necessary to send speakers on special subjects from a distance.

Many more speakers could be utilized in this work and any person who can give a good talk himself or who knows of someone who is qualified is requested to communicate with the Sub-Committee on the Speakers' Bureau.

F. H. Magney, *Chairman*

With regard to the report of the Committee on Public Health Education and the two sub-committee reports the Reference Committee declared as follows: That the report of the committee as a whole portrays evidence of an exhaustive and well-defined program and of outstanding accomplishments; that the college lecture courses described therein show that a series of well chosen subjects has been delivered by eminently well-qualified members of the profession; that the continuance of the excellent type of education carried on by the radio sub-committee and Doctor O'Brien is of vital importance to the Association and that extension of the program, particularly to the Duluth station, would be a valuable asset if it could be arranged; that in connection with the work of the Speakers' Bureau, a speakers' bureau should be created within each component society with a view to extending health education by platform talks throughout the state. In accordance with the recommendation of the reference committee the report was approved.

At the invitation of the Speaker, Dr. F. J. Savage of Saint Paul gave the following supplementary report in the absence of Dr. L. R. Critchfield, chairman of the Committee on Public Health Education:

I wish to express the thanks of Doctor Critchfield to Doctor Meyerding and his staff and to Mr. Rosell and his staff for their help in the past year in making our program a success. I wish also to give due credit to the affiliations with the Minnesota Public Health Association in putting over the work and to hope, also, that the association may continue.

The committee reports designated as "Medical Economic Reports" and reviewed by the Non-Scientific Reference Committee unnder the chairmanship of Dr. M. C. Piper follow:

COMMITTEE ON MEDICAL ECONOMICS

Members of the Medical Economics Committee and the sub-committees, as provided in the recently adopted constitution, held their first general meeting on Sunday, April 3, of this year in Saint Paul. This meeting was quite unique in the annals of medical organization since the work of the economic sub-committees which, though distinct, often overlaps and causes resultant confusion, could thus be coördinated and programs adjusted. Each sub-committee held its own round table discussions in the course of the morning, calling upon officers, councilors or representatives of other sub-committees for assistance as it might be needed. A general luncheon meeting for all followed, at which the Survey of Medical Facilities was outlined and discussed. Among the speakers were Dr. R. G. Leland, director of the Bureau of Medical Economics of the American Medical Association, Dr. C. B. Wright, trustee and Dr. R. L. Scammon, chairman of the Minnesota State Planning Board.

Details in the conduct of the survey were largely left in the hands of the Executive Secretary, Mr. R. R. Rosell, by the Committee on Medical Economics, which has general supervision of the work. Following is a brief summary of progress:

Information concerning scope and purpose was given initially in the *Journal of the American Medical Association.* The proposal was made first in Minnesota at the February County Officers' Conference, and since then it has been repeatedly publicized in Minnesota Medicine and in bulletins from the Executive Secretary's office.

Much credit goes to Secretary Rosell for his energetic conduct of the Survey, both from his office and in the field.

Council members have been asked to assume responsibility for the study in their own districts and several have held councilor district meetings to explain requirements to constituent county societies and to stimulate them to complete their portion of the work.

As a result, the Survey has made satisfactory progress in Minnesota. It is in advance here of many states, but much still remains to be accomplished, and this meeting should afford an opportunity for anyone who wishes it to get information and assistance. An exhibit on the survey and proper methods of filling out the Forms is on view in the exhibit hall.

The work of the editorial sub-committee has continued with the able supervision of Mrs. Fitzgerald, and we trust that the members are carefully reading the medical economics columns in which progress in medical economics is publicized each month. Members of the editorial sub-committee are Dr. W. F. Braasch, Dr. A. R. Barnes, Rochester; Dr. A. N. Collins, Duluth; Dr. Lennox Danielson, Litchfield; Dr. E. A. Meyerding, Saint Paul; and Dr. E. S. Platou, Minneapolis.

W. F. Braasch, *Chairman*

SUB-COMMITTEE ON PROFESSIONAL EDUCATION IN MEDICAL ETHICS AND SOCIAL AND ECONOMIC TRENDS

Education of undergraduates of the University of Minnesota Medical School in subjects related to medical ethics and to social and economic trends has been

under discussion. Heretofore lectures on these subjects have been given periodically to sophomores. Dean H. S. Diehl of the University Medical School is now working on a schedule of similar lectures for seniors which shall include also, at the suggestion of the committee, consideration of medical jurisprudence. The committee recommends that sterilization by vasectomy, except for purely medical reasons, be considered unethical practice by the House of Delegates.

Erling W. Hansen, *Chairman*

MEDICAL ADVISORY SUB-COMMITTEE

The Medical Advisory Sub-Committee has had numerous meetings with various other groups interested in lessening of malpractice suits against members. Articles have appeared in Minnesota Medicine, papers have been given at various society meetings for the purpose of better coöperation among members. A detailed report is to be given verbally before the delegates at this meeting.

B. J. Branton, *Chairman*

SUB-COMMITTEE ON STATE HEALTH RELATIONS

The usual assortment of problems related to its work have been referred to this committee and the committee has handled them in coöperation with other committees and with officers of the State Society. We have kept in close touch, also, with the State Board of Health, a representative of the committee having been present at virtually every meeting of the Board.

A survey of medical care at the State Tuberculosis Sanitorium was made by this committee in response to a request of the State Board of Control made to the Council and referred to us. This survey consumed a great deal of time and effort and was, we trust, satisfactory to those concerned. Thanks are especially due to Doctors Tuohy and Geer, who worked with the committee in the undertaking.

The committee is now making a preliminary study of the possibility of developing a program of periodic health examinations for Legionnaires that will be satisfactory to the profession. The request for assistance came from the Rehabilitation Committee of the State Department of the Legion, and we are coöperating with this committee. Various officers of the state association have been kind enough to work with the committee in this preliminary study.

T. H. Sweetser, *Chairman*

SUB-COMMITTEE ON LOW INCOME AND INDIGENT PROBLEMS

There are three classes to be considered in any discussion of the problem of ability to pay for medical services.

First: Those who are unable to pay any fee whatever. We believe it is the obligation of the federal, state and local governments to provide adequate medical care for this group. In Minnesota this problem has been well handled.

Second: Those who are able to pay moderate fees but are not able to assume unusual obligations incurred by sickness and its accompanying misfortunes; this is the largest group of all.

Third: Those who are able to pay for services rendered. They are omitted for obvious reasons from discussion at this time.

It is generally agreed that medical care of the second group, the "low-income group" is the real problem, and it varies in every part of the United States. Virtually every state in the Union has devised and tried out schemes for more adequate care of the low income group. Many of these schemes have failed. Some have helped in the solution of the difficulty in certain localities. The American Medical Association has watched the progress of all these schemes and has carefully correlated them with their effects; but no national solution has been found or advised either by the federal government or by the association, though the American Medical Association has volunteered to cooperate with the government in an endeavor to find a solution to the problem.

Various plans for Hospital Insurance are now in operation, such insurance being handled by the hospital groups without outside aid. If some plan of sickness insurance should be devised that would apply in all parts of the United States, the medical profession would demand some part in management of the program. It is a well known fact that the political management of sickness insurance would be a disaster, as it has proved to be by experience with such "set-ups" in foreign countries.

That furtherance of preventive medicine is a function of the federal governmnt is generally agreed. America leads the world in this field today; but much still remains to be done. Why not a program directed toward less sickness as a means of reducing the costs of medical care to all? Is not our problem essentially one of disease prevention with good or better medical care to all, rather than one of medical fees?

Surveys on medical care have been conducted in many states and cities by lay people without the aid of the medical profession. It is well for us to have their side of the story, but as in all other stories, there is another side. And the American Medical Association, with its state affiliates, is making an intensive survey by questionnaires to physicians, hospitals, nurses, health departments, welfare agencies, public and parochial schools and through colleges and universities to discover as nearly accurate data as possible on the needs.

Perhaps from all this a real evaluation of needs and costs to the low income group may be elicited. Then, possibly, a scheme may be devised whereby sickness insurance may assist in providing care which is in the reach of all. There are two tenets that physicians will insist upon in any case. One is that the federal government shall not assume complete control of anv plan that may be evolved; second, that the principle already held essential by the government, that the patient shall have free choice of physician, must be maintained.

Knowing well the burden placed upon those in the low-income group, the physicians of America are only too anxious to coöperate with the proper authorities to provide adequate and competent medical care to all.

The possibility of a program of rehabilitation of unemployable relief clients, similar to one now functioning successfully in West Virginia, has been discussed by this committee. The following recommendations were made:

1. That examinations made of all relief clients by the C.W.A. several years ago are now too remote to be of any value in laying plans for a rehabilitation program in Minnesota.

2. That the Minnesota State Medical Association will coöperate in such a program if the State Relief Administration believes the program worthwhile; but that it will be necessary to re-examine all relief clients as a first step toward formulating a program.

At the request of the Farm Security Administration, a plan for providing medical care for clients of the administration was drawn up by the committee and is now under discussion. In general, the plan provides for medical care for the clients at a 40 per cent reduction from prevailing fees in the locality to be paid within 90 days. The Administration, according to the plan, is to provide the doctors with names of the clients in their communities and to make it clear to them that medical care at such fees is only by special arrangement for the period of their association with the Farm Security Administration. Similar plans are in operation in other states.

W. A. Coventry, *Chairman*

SUB-COMMITTEE ON INDUSTRIAL RELATIONS

The following resolution is submitted by the Committee for action by Council and House of Delegates:

"Whereas in practice, the medical profession has always been in favor of the freedom of patients to choose their own medical advisers and

"Whereas only recently a law has been enacted in Minnesota giving the indigent the right to choose his own physician and

"Whereas there seems to exist an impression that the Minnesota State Medical Association is not fully in accord with this opinion.

"Therefore, Be It Resolved that the Minnesota State Medical Association declare itself in thorough accord and support of the principle that, in the interest of good public policy, the patient shall be permitted to choose his own physician, in cases involving liability and compensation insurance, as well as in private practice."

The Committee also recommends to the Council and the House of Delegates that insurance practice and compensation practice be subject to the code of ethics that governs private practice and offers for their consideration the "Interpretation of the Code of Ethics" which has been in force in the Hennepin County Medical Society since April, 1935, which is as follows:

"Physicians representing insurance carriers or employers in compensation cases or in cases involving public liability are expected to observe the rules laid down in Article IV, Section 3, Principles of Medical Ethics of the American Medical Association the same as physicians in private practice. A physician representing an employer or an insurance carrier may visit and examine as a consultant a patient in charge of another physician but should never take charge of or prescribe for the patient until after the other physician has relinquished the case or has been properly dismissed. This consultation should be arranged in the usual way by obtaining the consent of the attending physician. A request by an employer or an insurance carrier that a physician representing them take charge of the case shall not be considered a proper dismissal of the physician originally in charge. A physician representing an employer or an insurance carrier should never take charge of a patient who has been in charge of another physician unless the latter has been definitely discharged by the patient. In that case it shall be the duty of the physician representing the employer or the insurance carrier to explain to the patient that he has the privilege of choosing his own physician and to inquire whether he changed his physician by reason of duress, or intimidation, or misrepresentation. If the patient chooses to retain his own physician, it shall be unethical for the physician representing the employer or the insurance carrier to take charge of the case. Any case of doubt concerning professional judgment or management of the case or ethics as provided in Article 5, Principles of Medical Ethics of the American Medical Association should be referred to the Board of Censors of the Hennepin County Medical Society through the Ethics Committee for final decision."

A plan similar in general outlines to the Wisconsin plan for handling compensation insurance should be presented to the State Association for consideration. It is the opinion of the committee, however, that the problem differs from Wisconsin in Minnesota and it therefore suggests that a register be kept in every local medical society in the state showing the physicians who desire to engage in practice in which insurance companies are involved. Membership on this list would be optional with each physician; but any member in good standing in his local society should be eligible to enter his name. These names need not be posted or published but should be available for reference by employers, insurance companies or patients. Each local society should be privileged to decide whether it would adopt the plan and it should further have the privilege of adopting its own fee schedule.

M. S. Henderson, *Chairman*

SUB-COMMITTEE ON CONTRACT PRACTICE

Two years ago the chairman of the Committee on Contract Practice presented to the House of Delegates the standards relating to contract practice as simplified and revised by the Judicial Council of the American Medical Association for adoption all over the state. They were adopted at that time by the delegates and by a number of county and district societies in the state.

A report on the status of this action in all the counties of the state would be appreciated by the committee so that the matter can be presented again to societies that have not already acted.

The association of certain physicians with a fraternal organization which includes medical care in its benefits has been reported as a possible infringement during the past year. In some instances, physicians have been retained by the organization to take care of members and their families, thus introducing a third party into the relationship and also preventing free choice of physician to the patient. In both these particulars such a contract violates the official standard.

The matter has been under consideration by the Committee on Public Policy, however, with the result that the project has already been abandoned in several communities. Assurance has been given that it will be abandoned universally in the state by June 1 of this year.

The importance of the free choice of physician as a fundamental to the practice of good medical care cannot be brought too frequently to the attention of the physicians, in the opinion of the committee, or to the attention of others concerned in the delivery of medical care.

A so-called "hospital service contract" which includes medical services is being offered currently by certain insurance companies. The committee believes that the fee schedule for medical services should be eliminated from the contract and that the whole matter should be brought to the attention of the delegates.

F. A. Olson, *Chairman*

EDITING AND PUBLISHING COMMITTEE

Although business conditions in 1937 were adverse with regard to the sale of advertising—this applies especially to the last half of the year—your Editing and Publishing Committee reports some increase in the total revenue from advertising and subscriptions.

Minnesota Medicine averaged almost 100 pages an issue for the year, the total number of pages printed being 1,168. This is an average of 97.3 pages for each issue. Of this number 826 pages were devoted to reading matter and 340 to advertising. The reading pages included 109 scientific articles in addition to several articles and abstracts of articles published in the Proceedings of the Minnesota Academy of Medicine and the Minneapolis Surgical Society, numbering twenty-six in all. Eight case reports were published. This does not include the case reports included in the body of numerous scientific papers. In addition, the usual section features such as editorials, reports and announcements of societies, news items, book reviews and the Medical Economics section were given adequate space. The Medical Economics section this year totaled 79 pages, or an average of 6.6 pages each issue. Illustrations published with the various papers numbered 232, or an average of almost 20 an issue.

At the close of 1937, records showed the total number of paid membership subscriptions to be 2,147, with about 115 subscriptions carried the first part of the year as delinquent accounts. There were 180 nonmember subscriptions. Miscellaneous distribution, including single copy sales, exchanges, complimentary copies, advertisers' checking copies, et cetera, numbered 303 copies, leaving a surplus of about 150 copies for possible distribution in filling orders for back copies and for sample copies to prospective subscribers and advertisers. The total average distribution was 2,891

copies. At this time the total has increased to a point where 3,100 copies of the journal are required each month, and it appears that to meet requirements, at least that many copies will be required of each monthly issue during 1938.

Herewith please find a financial statement showing the total income and expense. This shows a breakdown of all the expenses incurred in connection with the publication of the journal during 1937 in every detail.

Effective with January 1, an increase in advertising rates announced more than a year ago, became effective. This should have a good effect upon 1938 income, and it is reasonable to expect, your Committee believes, that the advertising volume for this year should show a substantial increase over that of 1937. Of course it is understood that no definite assurance can be given to this effect owing to the uncertainties of business conditions. Up to and including the June number of this year, we have a net increase in display advertising of $350.00 over the corresponding period for last year, so it seems only reasonable to estimate a $500 or $600 increase for the year in advertising receipts.

The journal is also carrying eight pages in each issue of the Minnesota Medical History. This material is being kept standing in page form for the possible publication of a book after the work has been completed and presented through Minnesota Medicine. It is felt that the sale of this book will enable the state association to recover all the costs incurred in the publication of the history in Minnesota Medicine with a reasonable probability of a net profit.

Some economies have been effected and plans approved for a possible increase in revenue from sources other than advertising and subscriptions which your committee is confident will show a larger net return for 1938 than has been earned during the past three or four years.

However, it is only fair, in considering costs and income of your journal, to bear in mind that Minnesota Medicine is produced in such a style as to reflect a great credit upon the medical profession of this state; that it is well printed on good quality of paper stock, with an attractive cover and good typography throughout. No state journal in organized medicine has a higher standing. It is much better illustrated than the general run of medical publications. Obviously the cost of these illustrations amounts to a considerable sum during the year, but we believe that the membership desires that a high standard be maintained.

J. T. Christison, *Chairman*

The Reference Committee made the folowing recmendations and comments concerning the reports of the Medical Economics Committee, its sub-committees and the Editing and Publishing Committee:

That the House of Delegates might wish to have more detail as to the progress of the Survey of the Need and Supply of Medical Care than is given in the rather generalized report of the Committee on Medical Economics though the committee realizes that the survey is still in its infancy. A definite stimulus to action seems to be needed since, in some instances, it is understood that the councilors have not yet met with the various local societies to explain objectives and methods.

—That the individual societies should appoint committees of review to analyze and consolidate reports as they come in. The Committee feels that Minnesota is fortunate in having within its ranks the national

chairman of the Survey, that Doctor Braasch has undertaken a tremendous job and that the State Association should make every effort to complete its survey in the spirit in which it has been undertaken.

—That the Medical Economics feature of MINNESOTA MEDICINE is essential and should be continued.

—That the activities of the Sub-Committee on Professional Education in Medical Ethics and Social and Economic Trends should be extended in that members of county and district societies should meet with groups of internes for discussion of these problems while they are on their interne service. The Committee suggests further that county societies make it a part of their program to encourage new members in their communities, to call on them personally and to assist them in becoming acquainted with the relation of all these matters to the practice of medicine and to medical jurisprudence.

—That the Medical Advisory Committee is doing valuable work and the Committee hopes it will be continued.

—That the report of the Sub-Committee on State Health Relations be accepted as submitted.

—That a careful perusal of the report of the Sub-Committee on Low Income and Indigent Problems be recommended to all members. The Committee wishes to thank the Sub-Committee for its classification of indigency and suggests that the compilation of Survey Blanks will be simplified if this classification is followed. The Committee makes note of a new group of citizens forming itself into a position to request medical care at a 40 per cent discount of fees and asks an explanation of who may be included among the clients of the Farm Security Administration.

—That the resolution relative to choice of physicians proposed in the report of the Sub-Committee on Industrial Relations be adopted, also the code of ethics governing insurance and compensation practice and that the report as a whole be accepted.

—That the committee approves the principles proposed in the report of the Industrial Relations Committee and believes that the medical fee schedules presented in hospital service contracts of insurance companies should be considered by the House of Delegates and that such practices should be discouraged.

—That the report of the Editing and Publishing Committee be adopted and that the committee wishes to express its appreciation for the excellence of our state publication. The delegates accepted the reports with the recommendations of the Reference Committee.

Dr. W. F. Braasch, chairman of the Committee on Medical Economics, offered the following supplementary report on the Survey:

I can truthfully assure you, in the first place, that our progress with the Survey in Minnesota compares very favorably with other states in the Union. While the Medical Economics committee has general guidance, the work is largely centered in the office of the Executive Secretary, Mr. Rosell, and really he has done a very good job, proceeding systematically to coöperate to the fullest extent with committees, county societies and with allied agencies.

Only one of the nine survey forms prepared by the American Medical Association has been sent to each individual doctor in the local societies to fill out. The other forms have been sent through state organizations and agencies concerned with the activities in question. On the progress made by these coöperating agencies we can report with some degree of accuracy. The interest exhibited by these organizations and the promptness with which the forms have been filled out and returned is significant and encouraging.

Form No. 1, covering actual experience of individual doctors, has been answered fairly well. Some fail, however, to answer questions 7, 8 and 9, which call for their own solutions as to problems involved. These should not be left blank. There must be a solution to the problems involved in medical care for the indigent and we must have the help of the general practitioner in finding the solution.

Form No. 2 on hospital facilities and activities has been sent to all members of the Minnesota Hospital Association by Mr. A. M. Calvin, secretary. We understand a satisfactory return is coming in.

Form No. 3, concerned with nursing, has been sent for information on public health nursing to Miss Olivia Peterson, director of public health nursing of the State Board of Health, and to the Minnesota Registered Nurses Association for information on private duty nursing. Returns have been received from 35 counties this week by Miss Peterson and from four of the nine districts covered by the Registered Nurses Association.

Form No. 4 covering official health activities is in charge of Dr. A. J. Chesley, executive officer of the State Board of Health and member of the American Medical Association's advisory committee on the Survey, who has sent it to all community and county health officers of the state and received returns from 68 counties and seven communities.

Form No. 5 on public welfare activities is in charge of officials of the State Relief Agency, who have sent forms to relief workers in every county and received returns from 65.

Form No. 6 on health activities in the schools is in charge of the State Department of Education for the public schools. To date, 80 per cent of city and town schools and all county superintendents of the state have returned forms. One hundred and fifty of the 300 parochial schools who received forms direct from the state office have made returns.

Form No. 7 on health services in the colleges also went direct from the state office to the 25 colleges and universities of the state. Twenty-two have made returns.

Form No. 8 on medical service arranged for or provided by industrial, fraternal, mutual benefit, group hospitalization, community health or other similar organizations, or by county medical societies, is being handled direct by the state office.

Form No. 9 on activities and experience of wholesale and retail druggists was received at a later date than other forms, but is now in the hands of the State Pharmaceutical Association, and group meetings are being held in various parts of the state to stimulate interest and returns from the members.

As I have said before, to be accurate and to give a reliable picture of conditions all over the state on which to build improvements or readjustments, this Survey must be honest and it must represent all districts and classes. It was not planned as a statistical exercise but as an earnest and sincere effort to evaluate medical service in every county in the state and, as such, it is of importance to every member. Upon the

accuracy and honesty with which the work is done will depend the future of medical practice in Minnesota.

Dr. B. J. Branton, chairman of the Medical Advisory Sub-Committee, presented the following supplementary report:

First, we wish to commend the spirit of coöperativeness that is becoming more and more evident among our members. This spirit will eventually eliminate virtually all unwarranted malpractice cases in the state.

Second, we call your attention to the lessening of the size of verdicts awarded in malpractice cases during the past year. Many cases, of course, have not been brought to trial at all, even after papers were served. Many others have been settled as nuisance cases for a very few dollars. When it came to settlement, many $15,000 to $20,000 cases have been settled for from $50 to $150.

Third, the committee selected by the Minnesota State Bar Association to work with our committee is doing everything in its power to curtail illegitimate cases. In this connection, I wish to urge all of our members to become better acquainted with members of the Bar Association. Interprofessional meetings should be encouraged and will do much to iron out difficulties encountered by both professions. There are 1,700 members of the Bar Association in the state, men of the same caliber and type as our members, and they welcome an opportunity to become better acquainted.

Contacts with insurance company representatives and this committee have been mutually advantageous, also. The insurance representatives have brought to my attention the following matters which should be considered by all of us.

One is that a great many suits are being brought in order to avoid having to pay medical and hospital bills. The patient is disgruntled and brings suit for malpractice, often as a counter action when he is sued for the bill. In the case of such patients trouble can be avoided by waiting until the 25th or 26th month has passed before putting the bill in the hands of a lawyer.

Another is that many suits are being brought by indigent patients who are looking for easy money. The doctor should be very careful in handling both disgruntled and indigent patients.

A third is that reports for industrial and compensation cases and insurance companies should be made in detail so that the doctor will not be obliged to testify from memory on the witness stand or before a referee. Be sure, also, that you are testifying only as to the facts of the case and that you are not favoring either side. There is always the possibility that the patient may not get as much money as he anticipated from the insurance company and then he may turn and sue for malpractice, especially if the doctor has elaborated too much on the condition of the patient.

The professional testifiers among doctors are becoming fewer in number. Some of them have seen the error of their ways when their insurance has been taken away from them.

Our committee has learned much from our many outside contacts during the past year and we hope to be of service to our members. Any member who is sued should notify the state office at once. He will then receive a questionnaire which should be made out and returned immediately. The committee will then be at your service and every means will be taken to assist you.

Dr. T. H. Sweetser, chairman of the Sub-Committee on State Health Relations, presented the following supplementary report:

I understand that the State Board of Health proposes to establish another public health district in the Southeastern part of the state to include Dakota, Goodhue, Olmsted, Winona and, I think, Mower counties. They propose to establish an Arrowhead district in the Northern part of the state also.

We have discussed the matter of periodic health examinations for Legionnaires with the State Rehabilitation Committee of the Legion and have carefully examined the forms proposed by the Legion to see if they are complete and yet do not entail an excessive amount of work for the physician. We have advised, also, that the details be left for decision with the local medical society and that fees should be fixed in consultation with the local societies. It was agreed that Legionnaires who can afford to pay should be handled as private patients and that the legion would step in and help those who are unable to pay private fees; also that the physician-patient relationship should be preserved and that records should be kept by the physician who would be glad to furnish any information asked for by Legion officials or the Veterans' Administration upon request of the patient.

I am outlining all this so that you may have advance information in case the Legion post in your locality comes to you.

Doctor Piper requested from Doctor Coventry, chairman of the Sub-Committee on Low Income and Indigent Problems, an explanation of the status of Farm Security clients, also who would pay their loans.

Doctor Coventry: The government lends certain farmers certain amounts of money to maintain them on their farms until they shall be self-supporting. The money is not loaned for crop restriction or anything of that sort; it is merely done in preference to putting the farmer on direct relief.

Doctor Piper: I was wondering if the special fee for examinations for Legionnaires—I understand two dollars was suggested—would apply to Farm Security clients, also. Or is it only for Legionnaires?

Doctor Sweetser: Only for Legionnaires; but they all want a reduced rate. I don't know how the rest of you feel, but I don't believe that examination should be given for anything like two dollars. We are going to refer the fee question, however, to the local societies.

Doctor Piper: The examination calls for blood test, urinalysis and physical examination, does it not? There are more organizations each year asking for special fees. Just now it is the Legion and Farm Security clients.

Doctor Sweetser: I believe the fee for the examination for Legionnaires should be at least five dollars. If the fee is proper and our suggestions are followed I believe we could have no serious objections to the plan.

Doctor Piper also asked for an explanation of the "Wisconsin Plan" mentioned in the report of the Sub-Committee on Industrial Relations. The chairman was not present and the Speaker suggested that the committee make a supplemental report on the subject to be sent to the delegates.

Committee reports designated as "Officer and Council Reports" and reviewed by the Non-Scientific Reference Committee under the chairmanship of Dr. S. A. Slater of Worthington, follow:

REPORT OF THE CHAIRMAN OF THE COUNCIL

The most urgent business of the Council this year has undoubtedly been the reorganization of the state office made necessary by the leave of absence granted to Dr. E. A. Meyerding, who served us so long and so ably as secretary.

Office management was placed in the hands of Mr. R. R. Rosell, who previously served as assistant to Doctor Meyerding and who had established many close and valuable relationships with the official agencies whose activities involve medical care.

This action was taken on the recommendation of Doctor Meyerding at the meeting of July 25, 1937. As executive secretary, Mr. Rosell took over active direction of all organization activities on September 1 under instruction and advice from the Council and committee chairmen. On December 1, Mr. Rosell and Mrs. Sylvia Holliday were duly bonded for handling of funds and transfer of accounts was made.

Hand in hand with office reorganization, a cut in expenditures to keep within the income of our association was undertaken by the Finance Committee of the Council. A new budget drawn up on an annual instead of a biennial basis was recommended by the Finance Committee and adopted by the Council. This budget under which we are now operating provides for a saving over and above routine running expenses of the association of a sufficient amount to wipe out a deficit of recent years. We are living within the new budget and we hope the end of the fiscal year will see us in good financial condition. Thanks are due especially to the Finance Committee for its work in bringing about this essential adjustment.

It was the expressed wish of the Council that our Association should continue to work with the Minnesota Public Health Association just as we work with other health agencies to the end that all public health work in Minnesota should be effective and authoritative. This type of coöperation is a very important part of our function as a state medical association and is now being extended rapidly to include an intimate advisory participation, also, in the lay education program of the Women's Field Army of the American Society for the Control of Cancer.

Women's Field Army: At a joint meeting of the Council, the Committee on Cancer and representatives of the Women's Field Army, an executive committee was formed for the cancer organization to consist of certain designated officers of the State Medical Association, the American Society for the Control of Cancer and the Women's Field Army. The committee is in direct charge of the program of the field army and controls expenditure of funds (see Report of the Committee on Cancer for details).

In addition to routine work of the Council which includes, approval of applications for affiliate membership, ruling upon problems of ethics and organization brought by county societies, approval of expenditures, several notable special actions were taken as follows:

The Herman M. Johnson Memorial Fund was set aside in perpetuity, only the income to be used for the annual memorial lectureship.

An investigation of medical service at Ah-Gwah-Ching, state sanatorium for the tuberculous, was requested by the State Board of Control and assigned to the Committee on State Health Relations of which Dr. T. H. Sweetser of Minneapolis is chairman. A thorough and impartial investigation was made and the present director endorsed with valuable suggestions as to improvements in personnel and equipment needed at the institution. The report was turned over with the approval of the Council to the State Board of Control.

The advice and coöperation of the Council on many other phases of its program was asked of the Council by the Board of Control, including approval of its program for crippled children and for rehabilitation of tuberculous patients and appointment of a special committee to consult with the Department of Public Assistance of the Board on matters relating to standards of disability.

A special committee was appointed at the request of the Minnesota Hospital Service Association to study hospitalization problems in rural districts; inquiries concerning the advisability of approving commercial hospital insurance plans have come to the Council and the Council has been of the unanimous opinion that such approval should never be given, on principle, by members of the profession, noting further that lapses and loopholes have been discovered in some actual policies which might work hardship upon all parties concerned.

A joint committee of the state association and members of the Minnesota State Bar Association was suggested by the latter body and approved by the Council, which delegated the Medical Advisory Sub-Committee of the Medical Economics Committee to represent the medical body in this joint group.

The general plan proposed by the Committee on Diabetes for establishment of a Council on Diabetes of the Minnesota Public Health Association which should unite diabetics and function as an educational body received approval of the Council with the suggestion that, since Christmas Seal funds of the public health association may not be used for diabetes work, the Committee seek aid from other organizations such as the State Board of Health and also of philanthropically minded individuals for support.

Approval of the postgraduate courses now in their second year in obstetrics and pediatrics financed by Social Security funds and directed by Dr. E. C. Hartley, director of the Division of Child Hygiene of the State Board of Health.

The Council agreed to abide by the verdict of the Minnesota Society of Obstetrics and Gynecology on the suitability for public showing of the film "Birth of a Baby," and, as a result, the society having officially approved the film, it was shown to thousands of people at various points in the state this year.

A special committee was appointed to study the question of standards for physiotherapists looking to the possible licensure of this new professional group.

The Council directed all members, old and new, to fill out the new application blanks drawn up to obtain more extensive biographical information from our members, the blanks to be used as the basis for a new biographical file of members in the State Office.

The Council disapproved the suggestion which came from representatives of an out-of-state organization for a formal inter-professional organization in Minnesota, approving instead a letter sent to all county and district societies in Minnesota by Dr. F. J. Savage, chairman of the Inter-Professional Committee, suggesting frequent informal inter-professional gatherings in all localities for the purpose of better understanding and for the joint promotion of community welfare.

The plan for periodic examinations of all Legionnaires was approved in principle and referred to the Committee on State Health Relations for consideration of detail in conference with Legion officials (see Report of the Committee on State Health Relations).

The Council approved joint subscription to *Hygeia* and *Everybody's Health* on a special offer made by the Minnesota Public Health Association by which both magazines will be sent to members of the Legislature this year.

The term of office of the Chairman of the Council was set at three years, the incumbent being ineligible to immediate reëlection to office.

A total of ten all-day meetings were held by the Council during the year requiring a substantial sacrifice of time and money on the part of all. Other officers and committee chairmen also devoted large amounts of time and service to the work of the Association and the Council votes thanks to them for their con-

tribution and also to the Executive Secretary and his staff for faithful and efficient service and splendid cooperation with the Council during the past year.

GEORGE EARL, *Chairman.*

The Reference Committee recommended adoption of the report with the following changes:

—That paragraph five of the report be eliminated and that the following paragraph be substituted (this substitution was submitted by Chairman Earl, himself):

"It was the expressed wish of the Council that our Association should continue to work with the Minnesota Public Health Association. The advantage of the past coöperation between the Minnesota Public Health Association and the Minnesota State Medical Association is fully recognized and it is desirable that the cooperation continue as far as possible."

—That the part of the paragraph on group hospital service referring to commercial hospital insurance plans be eliminated.

—That the following comment should be made on the paragraph on postgraduate courses:

"Although your committee appreciates the value of refresher courses of this type when controlled by the State Association, nevertheless, we believe that other postgraduate courses sponsored by the State Association as in the past should not be neglected."

The delegates accepted the report with the changes and comments recommended by the committee.

REPORT OF THE COUNCILOR OF THE FIRST DISTRICT

Notable activity in the membership and in the component societies was noted during the year.

1. *Care of the indigent.*—County Commissioners have probably been as coöperative as necessities for economy would permit; an insufficient amount of money is available, however, for medical care of the indigent. In addition, relief clients have learned to demand the best and frequently ask for special tests, et cetera, that are not absolutely necessary, thus adding to expense in the individual case.

2. *Syphilis.*—Local health officers have complained of lack of coöperation financially in some instances, on the part of the local medical group, in the treatment of syphilis. County medical societies and local groups may have to make some more satisfactory financial arrangements with health officers if the campaign against syphilis is to be a success.

3. *American Medical Association Survey.*—Component societies in this district have been informed concerning details and some counties in the district have been active in carrying it on. Certain points that may be helpful have been brought out in discussion with physicians.

a. Local health officers may have difficulty in obtaining required information and should consult the State Board of Health on procedure.

b. Local town and village physicians should at some time review blanks filled in by schools, lodges and other local organizations in order to be sure that the local situation has been accurately covered and blanks gathered through state organizations should have approval of local physicians before tabulation is carried out.

c. Patients who are temporarily delinquent in accounts should not be reported as permanent medical indigents since many of these temporary delinquents have paid something on old bills and desire to be financially independent.

4. *Campaign of the Women's Field Army.*—Your councilor assisted in obtaining speakers throughout the district for the campaign of the Women's Field Army of the American Society for the Control of Cancer. The campaign in this district was successful.

Your councilor has been chiefly active during the past year in the study of finances of the Association as chairman of the Finance Committee of the Council. Report of the study is made by the Chairman of the Council.

H. Z. GIFFIN, *Councilor, Fifth District.*

REPORT OF THE COUNCILOR OF THE SECOND DISTRICT

All societies of the second district have been very active this year. All have held many meetings and several individual counties have organized medical clubs which meet six or seven times a year.

Dentists, lawyers and district judges of the locality were present at a well-attended and successful interprofessional meeting held by the Southwestern Minnesota Medical Society composed of medical men from six counties of the district this spring.

The Survey is under way in the district and I expect to be able to give a report of progress at the time of the state meeting.

L. L. SOGGE, *Councilor, Second District.*

REPORT OF THE COUNCILOR OF THE THIRD DISTRICT

Several important district meetings have been held during the past year, notably the meeting at Willmar at which all secretaries and presidents of the component societies met with Mr. Rosell and the Councilor to discuss phases of the economic situation as they affect medicine. Meetings of this type are of value, I believe, and should be held frequently.

The membership in the district has remained practically the same and a tendency to be closer in thought is notable among the members. Altogether, there is an unusually fine feeling, I believe, within the entire district.

B. J. BRANTON, *Councilor, Third District.*

REPORT OF THE COUNCILOR OF THE FOURTH DISTRICT

No complaints have been referred from this district for reference to the Council during the past year. Societies are active and membership somewhat higher than last year.

We have seen an improvement, also, in the handling of medical care for the indigent though conditions are not yet entirely satisfactory and we look to more satisfactory arrangements in all our counties.

J. S. HOLBROOK, *Councilor, Fourth District.*

REPORT OF THE COUNCILOR OF THE FIFTH DISTRICT

All societies of the Fifth Councilor District are active with the possible exception of Dakota County, where the situation is peculiar in that the county is relatively small in population and some of the physicians, being so close to the Twin Cities, are affiliated with the Ramsey and Hennepin County Medical Societies. The Dakota County society is primarily interested in problems related to care of the indigent and other such matters that must be handled on a county basis.

The problem of care of the indigent differs in status in the rural districts from the status in Ramsey County, where long established charitable institu-

tions and agencies have had charge of the work for many years and have, with few exceptions, continued to carry the indigent load. In the country districts, progress has been made in improvement of relationships with official agencies.

The Survey has been presented to all of the societies in this councilor district and here, too, progress is being made, particularly in the East Central and the Washington County Societies.

GEORGE EARL, *Councilor, Fifth District.*

REPORT OF THE COUNCILOR OF THE SIXTH DISTRICT

Forms for the American Medical Association Survey have been placed in the hands of Wright county members by Doctor Catlin of Buffalo, and I am now beginning to receive returns. The entire membership of the Hennepin County Medical Society has received the forms but no returns are available as yet.

The Hennepin County Medical Association has appropriated $1,000 to defray cost of collecting and tabulating results of approximately 10,000 tuberculin tests applied by private physicians in their own offices. This action is, in effect, a tuberculosis survey in private practice for which aid has been requested by letter from both the state and the Hennepin County tuberculosis organizations. If the project is successful I may suggest that a similar survey for the state be carried on under the sponsorship of the state medical association with the aid of the state tuberculosis association and interested parties.

C. A. STEWART, *Councilor, Sixth District.*

REPORT OF THE COUNCILOR OF THE SEVENTH DISTRICT

Both membership and attendance in this district are at a higher level than before, due chiefly to the activities of the secretaries of the two constituent medical societies, Doctor Badeaux and Doctor Libert, and also to a growing interest in the problems of medical economics. Care of the indigent by county physicians obtained formerly in two counties, and in a third county physicians were not paid either by county or township for care of the poor. In one of the two counties, free choice of physician was restored a year ago and in the other it was restored following passage of the "choice of vendor" clause. Negotiations are under way in the first for a better percentage basis for physicians and elimination of certain objectionable features; in the second, the plan is operating much more satisfactorily than before. In the third, there is a prospect of payment for medical services as a result of conferences between township and county officials and committees of the medical society.

The feeling of comradeship among physicians in this district appears widespread and sincere.

E. J. SIMONS, *Councilor, Seventh District.*

REPORT OF THE COUNCILOR OF THE EIGHTH DISTRICT

Satisfactory relations exist between members in this district and between the profession and the public, and, on the whole, between the profession and the relief agencies. The swing seems to me to be towards the profession, generally, rather than away.

This condition can be ascribed to a considerable extent to the efficient work of the society, especially its Executive Secretary and special committees; also, fair treatment accorded the profession by the Governor and the State Relief Agencies, as well as the high standard of service rendered to the people by the profession.

W. L. BURNAP, *Councilor, Eighth District.*

REPORT OF THE COUNCILOR OF THE NINTH DISTRICT

Medical affairs have gone smoothly in the district. Meetings have been well attended, programs have been instructive and papers carefully prepared during the past year.

The Range Medical Society, an affiliate of the county society, has been active, also, holding well attended meetings with varied and interesting programs and conducting, all during the spring, postgraduate meetings with outside lecturers.

The relief situation has been handled as well as could be expected in the past although there are rumors of trouble which we hope will not materialize in the future.

BERTRAM S. ADAMS, *Councilor, Ninth District.*

In compliance with the recommendation of the Reference Committee the Councilors' reports were accepted by the delegates.

REPORT OF THE TREASURER

The officers and Council of the Minnesota State Medical Association have been troubled for a number of years over the increasing deficit in the finances of our Association at the end of each fiscal year. During this year they have undertaken to reorganize our expenditures and set up a budget which should keep our expenditures within our annual income.

You will note on the enclosed auditor's statement, dated December 31, 1937, that an apparent surplus of $2,144.72 appears. This surplus does not represent a true picture of the finances of the organization.

This figure occurs on the books of that date because $3,135.00 had been taken in in dues for 1938 but had already been used to defray expenses for 1937. In addition, the statement shows an item of $1,953.51 in the savings of the American National Bank. In reality, $1,927.42 of this amount represents the money contributed for the H. M. Johnson Memorial lectureship fund which has been set aside by resolution to be used only in promoting that lectureship and does not represent income for the general purpose of the organization. Further, the statement shows a note for $1,000 borrowed from the bank in October, 1937, as *cash receipts.* This loan was necessary to tide the Association over until the first of the 1938 dues should come in. Thus, at the end of 1937, the Minnesota State Medical Association had overdrawn close to $4,000.

The new budget drawn up for 1938 by the Finance Committee of the Council has so reduced expenditures that this deficit will be wiped out, the Association will be able to live within its income during 1938 and have a small surplus at the end of the year.

MINNESOTA STATE MEDICAL ASSOCIATION
STATEMENT OF CASH RECEIPTS AND DISBURSEMENTS
FOR THE YEAR ENDED DECEMBER 31, 1937

CURRENT FUNDS		
Cash on Hand, December 31, 1936		$ 6,354.83
Cash Receipts, Year 1937:		
Dues collected, year 1936 and prior	$ 216.25	
Dues collected, year 1937	31,134.50	
Dues collected year 1938	3,135.00	
Total dues collected	$34,485.75	
Contributions to Johnson Memorial Fund	343.89	
Sale of diabetes books	84.44	
Bruce Publishing Company (Minn. Medicine)	774.36	
Transferred from Technical Exhibit Fund for credit of Annual Meeting expense	4,534.68	
Borrowed on notes payable	1,000.00	
Interest on savings accounts	54.43	
Dinner tickets (Annual Meeting)	265.69	
Sundry items	20.77	
Total receipts		41,564.01
		$47,918.84

Cash Disbursements, Year 1937:

Special committees:		
Educational Fund	$10,123.52	
Historical	1.50	
Hospital and medical education	58.82	
Medical economics	1,487.82	
Medico-legal advisory	290.81	
Medical relief	272.96	
Public Health education	4,634.21	
Radio	386.22	
State Health relations	159.62	
Unbudgeted committees	1,018.18	
Minnesota Medicine	4,293.50	
Furniture and fixtures	209.30	
Dues refunded	30.25	
Advance to employee	200.00	
Expenses, Johnson Memorial Fund	10.55	
Diabetes books	16.90	
Conferences and meetings:		
Annual Meeting	5,873.83	
Council Expense	412.35	
A.M.A. delegates	235.05	
County society meetings	72.47	
Other conference expense	81.05	
County officers' meeting	366.88	
Special session, House of Delegates	8.03	
Administrative expenses:		
Secretary's salary	2,800.00	
Secretary's travel expense	356.73	
Field secretary's salary	3,600.00	
Field secretary's travel expense	1,776.55	
Field secretary, balance of 1936 salary	300.00	
Treasurer's salary	100.00	
Stenographic service	3,056.55	
Rent	636.00	
Office supplies and printing	838.74	
Postage	531.51	
Telephone and telegraph	729.20	
Miscellaneous expense	805.02	
Total disbursements		$45,774.12

Cash on Hand, December 31, 1937:

American National Bank, Checking account	$ 64.94	
American National Bank, Savings account	1,953.51	
Farmers and Mechanics Bank Savings account	99.45	
First National Bank Savings account	26.82	
Total Cash on Hand		$ 2,144.72

W. H. Condit, *Treasurer.*

In compliance with the recommendation of the Reference Committee the Report of the Treasurer was accepted by the delegates with the following change. That the first paragraph should read as follows:

"The officers and Council of the Minnesota State Medical Association have been concerned for a number of years over the increasing cost of conducting the affairs of the State Association and balancing the budget. During this year they have undertaken to reorganize our expenditures and set up a budget which should keep expenditures within our annual income."

The Reference Committee also made note of the following: "In the opinion of your committee, if it should become necessary to secure funds to defray increasing expenses in order to balance the budget, the advisability of a small assessment might well be considered."

REPORT OF THE EXECUTIVE SECRETARY

On July 25, the Council granted the request of Dr. E. A. Meyerding for a year's leave of absence and instructed Mr. R. R. Rosell, assistant to the secretary, to take over the duties of executive secretary of the organization. Subsequently, in the interest of economy, the Finance Committee, with the approval of the Council, also ordered a complete separation of office management from the Minnesota Public Health Association, including a separation of bookkeeping.

This separation was completed as rapidly as possible and the Executive Secretary's office, although still housed as a tenant in the building owned by the Minnesota Public Health Association, has been independently administered to conform to the budget adopted for 1938 by the Council and with the limited office force allowed by that budget.

Recognizing the need for retrenchment, the Executive Secretary's office has endeavored to cut expenses wherever possible without curtailing, in any way, essential activities of the Association. These activities have, in fact, expanded since last September to meet the growing demands made upon the State Medical Association for advice and coöperation by all federal and state agencies concerned in any way in the provision of medical care.

Among the new activities within the State Office itself is the inauguration of a new biographical file of members with the new application blanks duly filled in with requested biographical information as backbone of the file. Magazines and newspapers have been clipped for personal information about members to add to the file, which consists of a stout manila envelope for each member. It has been suggested that the Women's Auxiliary aid by providing a clipping service by members throughout the state.

Following logically upon institution of the new file, the State Office has also assembled a complete set of Minnesota Medicine since the date of its first appearance in 1918, early issues being the gift of Dr. W. F. Wilson; also a complete set of its precursor the *St. Paul Medical Journal,* gift of Dr. J. T. Christison. Both are now suitably bound. Thanks to these members, the State Office, which should be the repository of many historical records about medicine in Minnesota, is now equipped with a complete file of its publications and with the beginnings, at least, of a biographical file of its members.

Launching the Survey of the Need and Supply of Medical Care in Minnesota is also an important new activity of the last few months reported upon elsewhere in the committee reports.

Tabulation of replies and information secured still remains to be done. Special funds may need to be appropriated to complete the work uniformly without wasteful loss of time.

As a result of action taken by the Executive Secretary and our attorney, Mr. F. Manley Brist, a new ruling on state income tax exemptions has been made permitting Minnesota doctors to claim exemption in making out state income tax statements on expenses incurred in attendance at medical meetings and in postgraduate education.

One of the principal functions of the State Office other than its routine office functions in respect to collection of dues, issuance of membership certificates, maintenance of the roster, has become the maintenance of close contact and understanding between the State Association and the public and private agencies engaged in ministering to the welfare of the needy and the indigent.

In Minnesota, we have had the opportunity to present the enlightened medical point of view in advance of new programs and regulations. The result of this mutual confidence and understanding in the midst of changing conditions is that no hasty proposals for state supported sickness insurance or politically installed coöperatives have emanated from any of the leaders in political or welfare work. Such alternatives have been relinquished in favor of an honest attempt to deal with medical problems fairly and realistically and with the advice of physicians whose interests lie in the advancement of the public good and of medical science and not in the advancement of party machines and political jobs.

The appreciation of all physicians is due to the public officials who have worked so willingly and courteously with representatives of our Association.

The situation with respect to our relations with these officials is in such marked contrast to the situation a few years ago that it would seem to deserve to be marked by the House of Delegates at this meeting.

As welfare work is now organized in Minnesota, virtually all official services with the exception of di-

rect relief and WPA are under the direction of the State Board of Control. The special thanks of our organization should be extended to Mr. C. R. Carlgren, chairman, to Dr. H. E. Hilleboe, director of Services to Crippled Children, and to Mr. R. E. Youngdahl, director of the Division of Public Assistance, for the understanding and good will they have displayed in working with our organization.

Among marked gains made during the past year was the inclusion in the Extra Session Laws of 1937 on relief of the choice of vendor clause which reads that "all counties shall permit free choice of vendor to relief clients for relief orders, provided the vendors chosen conform to the regulations of the Executive Council and of the responsible relief agency."

Equally important was the ruling of the Attorney General on this clause by which the right of a person on relief to select his own physician is established.

Thanks to the firm stand of S.R.A. officials that state aid could and would be withheld from any county that failed to conform to this interpretation even prior to the ruling of the Attorney General, difficult situations have been cleared up in many Minnesota counties. Remaining sore spots are quite likely to be cleared up as a result of the unequivocal ruling of the Attorney General, which ruling was secured largely through the personal effort of Mr. Brist, who has worked in the closest coöperation with the State Office on all phases of our program during the past year.

The actual state of medical relief and public assistance in general, so far as medical service is concerned, is indicated with reasonable accuracy in the booklet called "Facts and Figures" and issued last February by the State Office. Not only case loads and money spent, county by county, are included, but a brief and complete explanation of the functions and source of funds of each of the more or less entangled agencies that make up the welfare picture in Minnesota.

Responsibility for a knowledge of these agencies and functions must be assumed by the individual practicing physician.

The doctor's individual relationship to the community has changed in the last ten years and it is surely as much a part of his practice to know how to direct his patients who need help to the agency that will provide that help as it is to know how to treat the same patient medically. The State Office stands ready to answer inquiries but complete information on the part of the physician, himself, will contribute overwhelmingly to the successful working of the plan for medical care of relief and low income patients in Minnesota.

It is obvious, also, that physicians thus informed will be able to lay their fingers upon weak spots in the system and take the lead in correcting them.

One of the most effective approaches to the problem of medical care for the under-privileged is a vigorous, well-organized State Board of Health, and Minnesota has been exceedingly fortunate for many years in having such a board under the leadership of Dr. A. J. Chesley. Doctor Chesley works closely with the State Office and with the practicing physician.

The Executive Secretary has spent a considerable portion of his time in personal investigation of malpractice cases referred to the Medical Advisory Committee and also in attendance at meetings of county and district societies and at out-of-state conferences such as the Secretaries' Conference of the American Medical Association, the conference of insurance representatives and the Wisconsin State Medical Society at Madison. The State Office also arranged many committee meetings and conferences, the largest of which, outside of the state meeting, is, of course, the annual County Officers' Conference, at which attendance this year was nearly 100.

Membership of the organization is now 2,467 (2,363 active members plus 105 affiliate and associate members), representing an increase of 95 members over last year. There are 3,884 physicians licensed to practice medicine in the state and of the 1,417 who are not members a percentage are not engaged in practice in Minnesota; others are ineligible to membership for various reasons. A special effort should be made to enroll the remaining eligibles this year so as to increase income and cement the strength of the Association in the state.

It is now possible to report that the income from the fine technical exhibit at this meeting will cover all expenses incident to the Duluth meeting. Thus, no funds will be needed from the budget of the Association to finance the meeting. The Committee on Scientific Assembly has arranged a distinguished program and the local arrangements committee under the chairmanship of Dr. Russell J. Moe of Duluth has worked actively and enthusiastically with the committee and the State Office to make the four-day stay in Duluth pleasant and profitable.

Credit is due also to the State Office staff for the efficiency with which they have assumed new responsibilities and carried on the above full program with a smaller personnel and a minimum of extra help. A considerable saving in expenditures for office help has been made as a result over a like period last year.

The current outlook for maintaining accepted standards for medical practice is good. The load of the needy in the state has reached very close to half a million, however, and the relief picture becomes increasingly complicated. Medicine cannot hope to steer a straight course in the confusion of politics and scarcity of funds to meet the needs unless physicians are clear and definite in their public policy and unless they present a united front.

What may happen in Washington or even in our neighbor state, Wisconsin, cannot be foretold now. Whatever may be in store for us in Minnesota depends very largely upon the public spirit with which we shape our policy and advance to meet the need.

R. R. Rosell, *Executive Secretary.*

The Reference Committee recommended that the report of the Executive Secretary be accepted with the following two notations:

With reference to the paragraph which reads: "The situation with respect to our relations with these officials is in such marked contrast to the situation a few years ago that it would seem to deserve to be marked by the House of Delegates," the Committee said.

"The Committee wishes to commend the progress that has been made and hopes it will continue."

At the conclusion of the report the Committee also added this comment:

"Without wishing to detract in any way from the excellent work of the Executive Secretary, your Committee believes that attention should be called to the fact that much of the efficiency of the Secretary's office is based on a continuation of the activities and system established by the retiring Secretary, Dr. E. A. Meyerding."

The delegates accepted the report and comments.

REPORT OF THE SECRETARY

As your Secretary has been on leave of absence since September 1, 1937, pending acceptance of his resignation, his report will cover briefly certain activities from January 1, 1937, to September 1, 1937. The customary detailed report of the activities of the Secretary's office and Council activities will come from the Executive Secretary's office.

Those who took part in the organization of your

Association in 1924 know how little we had with which to start. To compare the Association at that date with the present Association, the progress, growth, harmony, and united activity that exists, seems astounding. We truly have a great State Medical organization, a fact recognized throughout the United States and making the organization the envy of all of the other states.

This great development is not the work of any one man but of a large group of unselfish, self-sacrificing medical men, and we have many of these left in the organization—the type of man who places the organization before any personal ambitions he may have.

This report would not be complete unless we mention some of this group of great workers who have made your present Association. Among them are: E. S. Boleyn, Charles Bolsta, S. H. Boyer, W. F. Braasch, W. L. Burnap, R. M. Burns, J. T. Christison, L. R. Critchfield, Carl B. Drake, George Earl, M. S. Henderson, H. M. Johnson, Starr Judd, O. E. Locken, the Mayos, J. A. Myers, N. O. Pearce, F. J. Savage, C. L. Scofield, L. L. Sogge, Theodore Sweetser, H. Longstreet Taylor, G. S. Wattam, W. W. Will, H. M. Workman, C. B. Wright, and others whose names will occur to you at this time.

Their hope and our hope is that their efforts will be appreciated and that the present group who are responsible will be as unselfish in promoting the best interests of our State Medical Association as were their predecessors.

Growth of Economic Problems.—With the increasing activity of Federal and State Welfare Agencies, our governmental administrators are becoming more intimately concerned with the health and medical care of the public, and medicine is consequently becoming deeply affected and influenced by these agencies.

We do not intend to go into detail but if you will consider the advances made in medical relief, the extension of the various state departments through federal aid in the care of the crippled and handicapped children, the many medical activities that have become part of the program of the State Board of Control, the increase in the activities of the State Board of Health, extending even to the education of the physician and allied groups, you can readily see that these proposed aids for medical care are only forerunners for more complete socialized medicine.

Therefore, it behooves the medical profession to become as compact a unit as possible so that its experience may be used to the best advantage for the public.

Contact Committees.—Your Secretary believes that the most important single accomplishment in his thirteen years' service in this office, was the organization of the County Contact Committees of three.

The necessity of the profession in each County organizing some kind of a group—may it be a medical club, a contact committee, or call it what you may—is of the utmost importance. This group must take upon itself the responsibility of looking after the interest of the profession and the health of the public within the boundaries of their County.

Public Health Education.—A few years ago, the public health education campaign which the Minnesota State Medical Association was able to put on with the Minnesota Health Association seemed to be a rather extensive program. Today, with the millions of dollars of federal funds being spent directly by the government for the work of the state and other official agencies, it is becoming more and more difficult for groups like organized medicine and the Christmas Seal organization to make their part of the public health education program noticed. Careful thought and planning are more essential now than ever before.

It is with extreme regret that your Secretary has noticed the growing separation of the Minnesota State Medical Association and its committees from the Minnesota Public Health Association. I can assure you, however, that the Minnesota Public Health Association, its officers, Executive Committee and members, will at all times stand ready to coöperate to the fullest extent with the medical profession. I, personally, shall make every endeavor to maintain whatever contact I can with organized medicine.

The relationship between the Minnesota Public Health Association and the Minnesota State Medical Association is emphasized by the medical men in the personnel of its officers and executive committee.

Speakers' Bureau.—One of the outstanding accomplishments of the past thirteen years has been the development of speakers who can satisfactorily present medical subjects to lay groups. We now have a considerable number of medical men who are acceptable to the laity.

One of the principal factors in the development of these speakers has been the College Lecture Course. Another was the short courses in public speaking which were given several years ago in various parts of the state. Many of the profession have now taken up public speaking due to the interest developed.

As time progresses, it will become increasingly important to have more medical men who are qualified to present our problems before lay audiences.

The development of medical speakers for lay groups has, thus far, been confined to scientific lines. Unfortunately, the opportunity to develop speakers on economic problems has not as yet presented itself. This is an important problem which confronts the medical profession now. It should be given immediate attention.

College Lecture Course.—The Minnesota Public Health Association and the Minnesota State Medical Association for the fourth consecutive year have sponsored the Health Lecture Course in colleges throughout the state.

This course consists of four monthly health lectures extending from October through January. College officials have been most enthusiastic in their praise of this project and its effectiveness as a means of student health education.

The Minnesota State Medical Association pays the honorarium and traveling expenses of the physician lecturer. The cost of the 1937-1938 course will be approximately $1,150.00 with an average cost of $16.45 per lecture.

The Minnesota Public Health Association does all the administrative work, the organization, planning, booking of speakers and publicity. A conservative estimate of the value of these services is well over $1,500.00. This may seem expensive. We believe, however, that this course is one of our most valuable programs.

We sincerely hope that the College Lecture Course will be continued as long as the schools wish to receive it.

Annual Meeting.—Some eight years ago, members of the Council and a group of members of the Minnesota State Medical Association suggested that a large institute of some kind which should represent the entire Northwest might be possible and advisable. In accordance with the policy of the American Medical Association, it was suggested that this meeting should be held under the auspices of the State Association. The Secretary was urged to build up such a meeting and attempted to comply.

Records show that the enlarged meetings of the Association since that date have been more and more successful and that the cost has not exceeded that of previous small meetings.

Previous to the 1932 meeting in Saint Paul, much of the annual meeting was conducted under the supervision of the local arrangements committee. This included the

handling of all exhibits, scientific, commercial, et cetera. Beginning in 1932, practically the complete supervision of the meeting was placed in the hands of your Secretary.

Audit—Oct. 4, 1924—Sept. 10, 1925—Local Supervision	
Convention Expense—Minneapolis (listed Convention Expense on this audit)	$1,775.99
1926—Convention Expense—St. Paul (listed Convention Expense on this audit)	1,150.13
1927—Annual Meeting Expense—Duluth	1,420.38
1928—Annual Meeting Expense—Minneapolis	1,242.08
1929—Annual Meeting Expense—St. Paul	1,921.11
1930—Annual Meeting Expense—Duluth	1,844.80
1931—Annual Meeting Expense—Minneapolis	1,459.13
1932—Annual Meeting Expense—St. Paul—State Supervision	1,513.13
1933—Annual Meeting Expense—Rochester—State Supervision	462.44
1934—Annual Meeting Expense—Duluth—State Supervision	1,544.00
1935—Annual Meeting Expense—Minneapolis—State Supervision	1,711.11
1936—Annual Meeting Expense—Rochester—State Supervision	393.83
1937—Annual Meeting Expense—St. Paul—State Supervision	867.60

Registration: The following comparison of registration is not only interesting but valuable:

Year	*Registration*	*Place*
1924	306	St. Cloud
1925	736	Minneapolis
1937	4256 (including physicians, Women's Auxiliary, exhibitors, members of allied professions attending the Congress of Allied Professions)	St. Paul

The 1937 meeting in Saint Paul will be memorable for many reasons. It gave unprecedented program representation to the scientific, social and economic problems of medicine. No other state medical association has been able to gather together at one time and for such a purpose so many organizations and groups who are today allied in the delivery of medical care to the people. Incidentally the participation in the meeting of so many organizations coming from many states made it possible to secure the St. Paul Auditorium for the meeting without charge—a saving of approximately $1,000 in the cost of the meeting.

Interprofessional Relationship Committee.—You are familiar with the report of the joint session of the Congress of Allied Professions held May 3, 1937, at the Lowry Hotel. Dr. Frank Savage, as chairman of the Interprofessional Relationship Committee, has done an outstanding piece of work. Other efforts are being made along this line that should be followed up.

During the entire period of your Secretary's service, public health meetings and interprofessional meetings of various types, such as meetings between the dental profession, the legal profession, pharmacists, etc., have been held throughout the state. I would urge that such meetings be continued. Invitations should be given to the various county health officers and public workers to sit in with the medical profession so they can get better acquainted.

Committee on Medical Economics.—Minnesota was the first in developing the type of Committee on Medical Economics which has proved so successful. The coordination of the various sub-committees centralizes and makes possible a uniform and conservative program in our state.

We have been fortunate in having had as chairman, W. F. Braasch, M.D., whose long experience in medical economics, both state and national, and well known executive ability have been invaluable in keeping us in close touch with happenings in this field throughout the country.

Committee on State Health Relations.—Your chairman of the Committee on State Health Relations is not only very competent, but a very energetic and thorough chairman. Theodore Sweetser, M.D., of Minneapolis, has done a splendid job. He has devoted unlimited time and effort to our Association. We owe a great deal to Doctor Sweetser.

New Constitution.—Your new constitution is not only one of the most advanced, but it has many unique features. The various graphs, showing the functions of the various committees, give at a glance the operation of our Association.

Every member should look over this constitution. It is a truly noteworthy document and is being copied by many other state organizations. In the main it was adapted from the constitution of the American Medical Association, especially in regard to the duties of the president and other high officers.

Housing Minnesota State Medical Association.—For almost fourteen years the Minnesota State Medical Association has been housed with the Minnesota Public Health Association. The administration of these two has been as one. We believe that this arrangement has been to the benefit of all.

Radio Broadcasting.—The Minnesota State Medical Association is unusually fortunate in having two members who are especially interested in radio broadcasting.

R. M. Burns, M.D., chairman of your Radio Committee, is not only interested, but is well informed and has done much to put our radio program in the foreground. Doctor Burns is well able to meet any situation that may arise in the radio program.

Wm. A. O'Brien, M.D., is the foremost health commentator in the United States and we are very fortunate to have such a gifted speaker devoting himself to the dissemination of authentic health information.

Tribute to Dr. H. M. Workman.—Everyone who has been closely associated with the Minnesota State Medical Association during past years appreciates the great sacrifices and worth of that grand old man, Dr. H. M. Workman. Throughout his professional career he was intimately associated with guiding the policies, finances and management of this organization.

During that time his experiences taught him much regarding the medical profession, its members and the relationship with the public.

He was very fixed in certain of his policies, especially regarding the finances of your organization. As I grow older, I appreciate more and more that this attitude came from the wisdom of his many years of experience.

It was Doctor Workman who always believed that the medical profession should be organized as county units. Your county contact committees are an adaptation of his belief. He believed that the medical dues and funds were the most precious treasure that the medical man possessed and must be guarded in every possible manner.

All of us would do well at the present time to follow closely the policies of Doctor Workman. Personally, I am grateful to have had Doctor Workman as my medical economic preceptor.

Financial Obligations.—For more than 13 years your Secretary has had practically complete responsibility of the business and office details of your organization, the only exceptions being the Committee on Public Policy and Legislation, Chairman, Dr. H. M. Johnson and now Dr. L. L. Sogge, and the Publishing and Editing Committee of Minnesota Medicine. The Council usually met four times a year. Policies were formulated by the Council at its meeting and in the interval by your officers.

The Finance Committee of the Council has had direct supervision of the making of the Budget and has been directly responsible to the Council for the expenditures of the same. Other expenditures required a vote of the Council as a whole.

The only protection against political, legislative and governmental experimentation, including national, state and local, is that provided by your membership dues,

which amounts to some thirty thousand dollars—a very insignificant sum to pay for an insurance premium to protect the health of the public and the standing of our profession.

We used what we thought was the greatest economy and efficiency in handling your funds and affairs. I am proud of my record, and I am proud of the resolution passed by your Council as published in Minnesota Medicine in January, 1938.

It has been reported that some of you have said that the affairs of our State Association are a small business because only thirty thousand dollars is involved, but let me tell you that it is by far the most vital business in the state as far as the interests of the medical profession and the individual doctor are concerned. It is the only protection the doctor has against the inroads on his freedom and the attacks that are being made on him today in his relation to the public.

Insurance Premium.—The Minnesota State Medical Association has about 2,500 members from the total of more than three thousand medical men practicing in Minnesota. A conservative estimate of the cost of preparing a medical man to practice is at least fifteen thousand dollars; it is probably much more. The profession has an investment of some forty-five million dollars in the original preparation to practice medicine.

In addition, there are many hospitals, clinics, and other institutions that are dependent upon the medical profession. Your medical school, University Hospital, Mayo Clinic, State institutions, church institutions, hospitals, are all more or less dependent on the independence and successful future of the medical profession. Undoubtedly the total investment dependent upon the medical profession runs into hundreds of millions of dollars in Minnesota.

You will agree that every precaution, every effort and the best possible personnel should be sought to protect medical care of the people of Minnesota.

Finance and Reserve Fund.—During my term of office, the expenditures seldom exceeded our income. Most of the budget items, supervised by your Secretary, were underspent. At each Council meeting regular reports of the budget and finances were submitted. The Finance Committee of the Council received special reports in addition. It was necessary to borrow money only twice to tide over the year end. Your auditors, Shannon & Byers, in their annual audits, including 1936, stated: "The books and records of account are adequate for the needs of the Association and have been neatly and accurately maintained."

The Fiscal Agency account was increased some $20,000 odd. Special credit belongs to Dr. Frank Savage during his term as Chairman of the Finance Committee, and Dr. C. B. Wright as Councilman, for the growth of reserve fund. To Dr. H. Z. Giffin, Chairman of the Finance Committee since 1932, belongs the credit for his interest and study of the investments of this fund. We believe that the Fiscal Agency Fund should be several times the present amount.

Conclusion.—The finances, both current and reserve, should receive the most careful attention. Every effort should be made to increase both, to meet the many emergencies that will arise.

The strength of the medical profession lies in its unity. No other group has the training to care for the health of the public as ours has. Consequently, a solid front will permit our profession to guide its own destinies and protect the health of the public.

The medical student should have some training in medical ethics, economics and public relations.

Every medical unit, no matter how small, must appreciate its importance in the problems that confront the medical profession today. These problems may be local or national.

Small groups increase their strength by alliances. Every opportunity must be taken by our profession to have the public appreciate our importance in the social and political organization.

Those responsible for the leadership should leave no stone unturned in protecting our interests both inside and outside the organization.

E. A. Meyerding, *Secretary*

In compliance with the recommendation of the Reference Committee the report and also the resignation of the Secretary to take effect at once were accepted by the delegates.

Chairman S. A. Slater read the resignation of Doctor Meyerding as follows:

It is with deep regret that I tender my resignation, to become effective at once, as Secretary of the Minnesota State Medical Association. You are cognizant of the fact that I submitted my verbal resignation May 5, 1937, and that I have been on leave since September 1, 1937, and I now deem it wise in justice to myself to make this leave permanent. In justice to the organization, I ask the House of Delegates to accept my resignation this evening so that some one can be elected this week to fulfill the office.

In the summer of 1924, I unofficially assumed the duties as your Secretary. On the first of January, 1925, I officially became your Secretary, a period of practically fourteen years in which I served as executive officer of the Minnesota State Medical Association.

I look upon my work with the Medical Association during these years as the happiest and most interesting in my life. The friendships that have come about through close association in the work will mean much to me throughout my life. I wish to take this opportunity to extend thanks to the members of the Medical Association for the fine coöperation which made it possible for our organization to develop into one of the most progressive in the country. I wish especially to thank the officers and members of the Council and others who have given long hours and much energy in volunteer service.

I am proud of my association with the Minnesota State Medical Association and the American Medical Association and my profession. It is a satisfaction to have been of some assistance in solving our many problems, organizing, developing, and aiding in establishing before the Minnesota public the greatness of our profession.

While I am now stepping out of official service with the Medical Association, my interest and coöperation in the work will continue. Some of you will remember that in my earlier years I frequently paraphrased Decatur's memorial speech as follows:

"Our profession, in her intercourse with those outside, may she always be in the right; but right or wrong, our profession."

I shall always adhere to this precept.

At all times I shall be at your service, and shall be only too happy to assist in any way possible. In leaving, I urge close coöperation and harmony in order that our Association may continue to keep its place of leadership.

E. A. Meyerding, *Secretary.*

The Non-Scientific Reference Committee on reports designated as "State Health Relations reports," of which Dr. A. H. Zachman of Melrose was chairman, reported as follows:

INTERPROFESSIONAL RELATIONSHIP COMMITTEE

Our major objective has been to foster establishment of local interprofessional relations committees in every county. In the past two or three years the state committee has met with groups of nurses, pharmacists and hospital administrators for the discussion of common problems. Valuable as these meetings have been in the

creation of better feeling and better understanding, it has been the feeling of the committee that the value would be greater if the same type of meeting could be extended to every county of the state. These local interprofessional meetings could render major service in the preservation of medical standards in times of legislative stress, in spreading sound doctrine to offset possible radical demands for state medicine, in backing the American Medical Association in their present study of medical care and, later, in their conclusions on the solution of the problem.

At a meeting of nurses in Minneapolis, attended by your chairman, government aid to tax-supported hospitals for the purpose of paying salaries of nursing instructors was advocated by the state director of education. This program was proposed on the basis of a report by his department on nursing education in Minnesota. The average nurse, according to this report, appears to be a downtrodden individual who sometimes works 84 hours a week, is poorly fed, badly housed, exploited and inadequately trained by the hospital and who graduates with health seriously impaired and without proper education. Not all hospital people or superintendents of nursing agreed with the report. One of the latter agreed that it might be true in isolated cases but that, in general, the report was incorrect. Mr. Amberg, superintendent of the University hospitals, showed that nursing education has been improved, hours reduced and curriculum revised, with students rotating on the various services. Cost of training has increased at the University hospital by $20,000.

At Nassau hospital in Mineola, Long Island, four graduate Minnesota nurses were found recently to be in charge of departments because, according to the chief of staff, "they seem to be the best trained women we can find."

A number of grievances from pharmacists were brought out in discussion following an address by the chairman before the Minnesota State Pharmaceutical Association, April 26. It was suggested that these grievances should be ironed out locally in interprofessional meetings between doctors and pharmacists; also that, although they had been informed two years ago that space would be allowed them to discuss these matters in Minnesota Medicine, no advantage had been taken of the offer.

F. J. Savage, *Chairman.*

In compliance with the recommendation of the Reference Committee, the report was accepted by the delegates with following comments by the Reference Committee.

"We feel that the meetings sponsored by the Interprofessional Relationship Committee will work to the mutual satisfaction and benefit of all interested groups, namely, nurses, pharmacists, hospital administrators and dentists and also the legal profession, which happened to be left out, perhaps inadvertently, by the committee, but which we shall like to add to the group.

"We feel, also, that the report on nursing education in the state is decidedly biased and does not represent the true condition in the field of nursing education. We recommend that the delegates familiarize themselves with this nursing education report so that they can discuss it intelligently if the need should arise."

Chairman Savage (supplementary report): One cannot read Doctor Earl's report or Mr. Rosell's report without being impressed with the fact that we can do much for the future of the medical man by these friendly get-togethers. The plan for these local interprofessional meetings met with the approval of the Council. The purpose is to create good feeling and an intelligent understanding of medical problems and the result should be the creation of a friendly body of people throughout every county in the state which should be of tremendous assistance in the shaping of our public policy. I know of two such meetings, one in Doctor Sogge's district and the other in Winona. There may have been more.

Doctor Sogge (speaking at the request of the Speaker): Eighty-eight were present at our interprofessional meeting in Worthington, including the judge of the district. I agree with Doctor Branton that an intimate relation between the doctors and the attorneys in a community is a fine thing. The attorney who knows the doctor's problems is not going to be so quick to start a lawsuit in town, even though it may appear to be a chance to make some money. I am very enthusiastic about interprofessional meetings and so, I believe, was every doctor, druggist and attorney who attended our meeting. We are going to try to have one every year.

Doctor Giffin: I have a communication from Doctor Wilson of Lake City telling of a meeting held there by their interprofessional relations committee, attended by fifty people, including physicians, dentists, nurses, pharmacists, hospital executives and representatives of the various relief agencies. The problem of medical care for the indigent was discussed. Every profession and agency was represented by a speaker and a much better understanding was created on their joint difficulties.

Doctor Wilson (speaking on the subject at the request of the Speaker): We had a worthwhile meeting with the pharmacists at Winona this year. Two speakers from the state pharmaceutical association spoke, and we discussed each other's points of view and enjoyed the whole meeting very much. Six months later the pharmacists invited us to a meeting with them. The meeting was addressed by medical men and valuable discussion followed. I think these meetings should be promoted throughout every county in the state.

An oral report on the work of the Committee on Public Policy was given by Doctor Sogge, chairman, and Mr. F. Manley Brist, attorney for the Minnesota State Medical Association, and accepted by the delegates. No transcription was made of this report.

No report was presented by the Committee on University Relations.

The Necrology Report was presented as follows by Dr. Richard Bardon, representing the Historical Committee:

NECROLOGY REPORT

During the last year, the Association lost forty-four members by death. Thirty-six of these were active members and eight were formerly active members or members who had retired from the Association. The list of deceased members follows:

MEMBERS

Carl M. Anderson, Rochester; J. Fowler Avery, Minneapolis; John T. Bowers, Bemidji; Charles W. Bray, Biwabik; Edward J. Brown, Minneapolis; Charles P. Dolan, Worthington; Charles A. Donaldson, Mesa, Arizona; Frederick C. Drenning, Duluth; Julian A. DuBois, Sauk Center; George Edward, Canton; Martin J. Fiala, Duluth; Herman W. Froehlich, Minneapolis; John J. Gelz, St. Cloud; Clarence W. Golden, Tyler; Frank B. Hicks, Grand Marais; Earl Jamieson, Walnut Grove; DeWitt C. Jones, St. Paul; Raymond W. Lagersen, Minneapolis; Hans M. Lichtenstein, Winona; Frederick W. Logan, Blue Earth; Elias P. Lyon, Minneapolis;

Martin L. Mayland, Faribault; Patrick H. Mee, Osseo; Clarence R. Morss, Zumbrota; Henry T. Norrgard, Milaca; Homer F. Peirson, Austin; Donovan Penheiter, Bagley; Ralph St. J. Perry, Minneapolis; Clarence E. Persons, Marshall; William C. Portmann, Jackson; John T. Rogers, St. Paul; Philemon Roy, St. Paul; Roy A. Schnacke, McGregor; Oscar H. Ternstrom, Minneapolis; Henning F. B. Wiese, Minneapolis; Warren Wilson, Northfield.

FORMER MEMBERS

Frederick H. Aldrich, Belview; George S. Cabot, Jamestown, North Dakota; F. Emerson Daigneau, Austin; Joseph E. H. Garand, Dayton; Amos Leuty, Morris; Ira M. Roadman, Minneapolis; Jorgen G. Vigen, West Los Angeles; James D. Weir, Beardsley.

At the request of the Speaker, the delegates stood with bowed heads for a moment in tribute to the memory of these deceased members.

NATIONAL HEALTH CONFERENCE

Following announcements of the next day's committee meetings the Speaker introduced Doctor Abell, president of the American Medical Association, who spoke as follows:

Mr. Speaker, members of the House of Delegates: Perhaps you will be interested in the background of the National Health Conference which is meeting in Washington, July 18, 19 and 20.

As most of you know, we have been advocating a federal department of health headed by a cabinet minister since 1875. The request has been made to successive administrations and refused on the ground, I believe, that the money expended by federal health agencies did not justify creation of a separate department. The validity of this excuse may be doubted when we consider the various agencies of the federal government today whose functions involve health or medical care. Of the beds available for medical care in this country, approximately a million are controlled by government agencies, including state and municipal governments. In addition, of course, there are the public health functions in the charge of the Department of the Treasury; the food and drug administration of the Department of Agriculture; the maternal and child welfare agencies of the Department of Labor; the Coast Guard Service in the Department of Commerce; Indian welfare in the Department of the Interior; medical service for the Army and Navy under the War Department; medical service for veterans under the Veterans' Administration; and there are also medical functions involved in the work of other bureaus such as the Resettlement Administration and the WPA. The aggregate expenditure for all these must amount to a considerable sum.

The result is that an Inter-Departmental Committee has been appointed during the present administration in Washington to recommend ways and means of coordinating all of the health and welfare activities of the federal government. This committee consists of representatives of five departments; Agriculture, Labor, Commerce, the Treasury and the Social Security Board. The chairman is Miss Josephine Roche. A technical committee on medical care was appointed by the committee and it was under the auspices of this technical committee that the National Health Survey, carried on almost entirely by WPA workers, was made. This survey, designed to present a cross-section of the country, was carried on, I believe, in only nineteen states.

The report of the Inter-Departmental Committee was presented to the President in February, and whether or not one agrees with all of the suggestions and data contained there it is one, I think, which should be considered carefully by everyone who is interested in the health movement in this country.

It starts by paying a tribute to the medical profession for its accomplishments in bringing about the decrease in mortality and the increase in longevity. It then takes up special problems in the control of various communicable diseases. Tuberculosis can be reduced 50 per cent below the present level, for instance, by correcting conditions in industrial life that tend to make people susceptible to it, according to the report. Syphilis, malaria and diseases of childhood are considered; also the degenerative diseases of advancing age—cancer, diabetes, arteriosclerosis, arthritis, nephritis—in relation to the income of the various groups of the population, pointing out what has long been patent to every thoughtful person, that the amount of disease is much higher among the lower income and indigent group than among those of higher incomes above $3,000 a year.

The fact that adequate fuel, food, clothing and shelter may in themselves be a factor in the health of people in the lower income brackets is not considered.

The number of physicians in the country is considered to be adequate by the report, though better distribution should be made. The number of dentists, now about 70,000, is believed to be only about half the number required, and hospital beds are inadequate. In the larger centers, of course, hospital beds are considered abundant for the needs, but the statement is made that in rural communities there are some 18,000,000 people who live thirty miles or more from the nearest registered hospital. This last finding is not in harmony with findings of the bureau of medical economics of the American Medical Association, which show that there are only thirteen counties in which the population density is five to each square mile and the total population, some 68,700 in which the people live thirty miles or more from a registered hospital.

The report considers that public health nurses should be increased from 18,000 to 65,000; that hospitals and diagnostic services should be made within easy access of all communities.

The entire program of recommendations should be met by tax funds or Social Security funds, according to the committee.

Some further interesting observations by Miss Roche made in an address in New York before the American Public Health Association, indicate that the 40,000,000 people in the United States whose family incomes are less than $1,000 a year are considered indigent by the committee. The group of 50,000,000 with family incomes of less than $2,000 are considered medically indigent; in other words, they are able to buy food, clothing, shelter, but not medical care.

One may, perhaps, differ with Miss Roche in this matter. In New York City, $2,000 a year may well constitute medical indigency. In some communities, however, $2,000 constitutes independence and in others affluence. Thus, I am sure we cannot all subscribe to the statement that the 50,000,000 people with an annual income of $2,000 are medically indigent. Furthermore, one does hate to believe that 90,000,000 out of the 130,000,000 people in this country are worthy objects of federal bounty and medical service. I know of no way to reach an estimate of the cost of such service to 90,000,000 people, though possibly costs of medical service to government employes in the Canal Zone may provide an indication.

As you know, all of the inhabitants of the strip of land ten miles on either side of the Canal, together with Cristobal on the East and Balboa on the West, are government employes. There are no indigents and no one who has not adequate food, clothing and shelter. The government provides complete medical services at a cost, without including construction and equipment costs, of approximately $25 a year per person. To provide such care for 90,000,000 people would cost $252,000,000 a year without considering for a moment the funds needed for construction and maintenance of buildings and equipment.

Now the Inter-Departmental Committee has called a

conference to be held in Washington to present, according to the invitation, ways and means to prevent loss of efficiency in our people from illness and for reduction of economic burdens caused by illness. Also, proposals embodying such a program to be made to representatives of the government.

Of course, nobody knows what those proposals will be. I feel, however, that this conference will enable us to know what the attitude of the government toward the practice of medicine will be, and I sincerely hope that some proposal will be made for the improvement of the condition of the indigent, at least, upon which all of us may agree.

The following resolution proposed by Dr. B. A. Smith of Crosby was adopted by the delegates.

"The House of Delegates of the Minnesota State Medical Association wishes to express its appreciation to Mr. C. R. Carlgren, chairman, and through him to Mr. B. E. Youngdahl, Director of the Division of Public Assistance, and to Dr. H. E. Hilleboe, Director of Services for Crippled Children, as well as the entire State Board of Control for their sympathetic and intelligent understanding of medical problems of Minnesota, and for their fine coöperation with the Minnesota State Medical Association in the handling of all medical phases of their work."

The following resolution was proposed by Doctor Zachman and adopted by the delegates with the suggestion that the name of Dr. S. E. Gilkey, medical advisor of the State Relief Agency, be included in the resolution.

"The right to choose his own physician is recognized as fundamental to good medical care for all classes of patients, and the thanks and appreciation of all physicians are due especially to Mr. Aufderheide and his associates of the State Relief Agency for the vigorous manner in which they have interpreted and enforced the provision of the new relief law guaranteeing this right to relief patients in Minnesota. Appreciation is also due to these officials for the readiness and understanding with which they have assisted physicians wherever possible to improve the standards of medical care for the needy."

Following reports by the delegates to the American Medical Association, Dr. W. F. Braasch, Dr. J. T. Christison and Dr. W. A. Coventry, of the meeting of the American Medical Association in San Francisco, the meeting adjourned to be re-convened at 6 p. m., Wednesday, June 29, 1938.

HOUSE OF DELEGATES

Second Meeting
Wednesday, June 29, at 6 p. m.

By motion duly made and seconded it was unanimously agreed to dispense with reading of the minutes of the last meeting.

The Council having no further report for the House of Delegates, the Speaker called for announcements of the next day's events.

The following resolutions were proposed by delegates and adopted by the house:

"The interest and devoted effort displayed by every member of the St. Louis County Medical Society, and particularly by the committee on local arrangements, has added materially to the value of our program and to the comfort and convenience of all who are in attendance at this great meeting. The thanks and appreciation of this House and also of the Association are hereby extended to them for the splendid arrangements made by them for this meeting."

"In its generous contribution of space for our sessions and in its courteous attention to the comfort of our members, the Hotel Duluth has contributed greatly to the success of this meeting. The thanks of the House of Delegates is hereby extended for this service."

"Proper newspaper reports of the proceedings of a state medical meeting add greatly to the interest of our members and they serve also as an important avenue of public education on public health. The House of Delegates extends its appreciation to the *Duluth Herald and Tribune,* especially, and to other Minnesota newspapers for their generous contribution of space to information about this meeting."

* * *

"An unprecedented amount of radio time has been put at the service of our Association at this meeting by stations WEBC and KDAL, not only for advance announcements, but to permit the public to listen to our distinguished guests on medical problems of interest to audiences. The thanks of this House is extended to both stations for their fine coöperation in this matter."

* * *

"The thanks of the House of Delegates should also be extended to the Duluth Chamber of Commerce for their excellent coöperation in all of the arrangements for this meeting and for the efficient help they have given us in registration of members."

* * *

"The thanks of the House of Delegates should be extended to the Minnesota Arrowhead Association for their courtesy in extending the facilities of their offices in the Hotel Duluth for this meeting and for their contribution to the pleasures and comfort of those who attended the meeting."

* * *

"The thanks of this House should be extended to the Kiwanis Club of Duluth for their courtesy and friendliness in presenting the beautiful basket of flowers for our platform."

ELECTION OF OFFICERS

The Speaker then called for nominations for the office of president-elect.

Dr. George Earl of Saint Paul was nominated for the position of *president-elect* by Dr. R. B. Hullsiek of Saint Paul in behalf of the delegates from the Ramsey County Medical Society.

There being no further nominations, it was moved, seconded and carried that the nominations should be closed and that the secretary should cast a unanimous ballot for Doctor Earl for the office of president-elect.

Dr. J. C. Jacobs of Willmar was similarly nominated for the position of *first vice president* and, there being no further nominations, it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for Doctor Jacobs for first vice president.

Dr. A. M. Hanson of Faribault was nominated for the position of *second vice president* and, there being no further nominations, it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for Doctor Hanson for second vice president.

Dr. B. B. Souster of Saint Paul was nominated by Doctor Hullsiek for the position of *secretary* to fill out the unexpired term of Doctor Meyerding, whose resignation had been accepted by the House, and also to serve for the year 1938-39. There being no further nominations, it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for Doctor Souster for secretary.

Dr. W. H. Condit of Minneapolis was nominated to succeed himself for the position of *treasurer* and, there being no further nominations, it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for Doctor Condit.

Dr. A. W. Adson of Rochester and *Doctor Will* were nominated for the position of *speaker of the House of Delegates.*

Dr. Joel Hultkrans, vice-speaker, was asked by Speaker Will to take the chair and, upon Doctor Adson's request that his name be withdrawn from the nomination, it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for *Doctor Will* to succeed himself as *speaker of the House of Delegates.*

Doctor Will resumed the chair and *Dr. E. A. Meyerding* of Saint Paul was nominated for the position of *vice speaker.* It was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for Doctor Meyerding for vice speaker.

Dr. H. Z. Giffin of Rochester, *councilor of the first district, Dr. L. L. Sogge* of Windom, *councilor of the second district,* and *Dr. B. S. Adams* of Hibbing, *councilor of the ninth district,* were nominated to succeed themselves as councilors of their respective districts. It was moved, seconded and carried in each case that nominations be closed and that the secretary cast unanimous ballots for each as councilors.

Dr. E. M. Jones of Saint Paul was nominated as *councilor of the fifth district* to succeed Dr. George Earl, previously elected to the position of the president-elect, and it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous vote for Doctor Jones as councilor of the fifth district.

Nominations were called for to fill the positions of two *delegates to the American Medical Association* with their *alternates* whose terms expired.

Dr. W. F. Braasch of Rochester and *Dr. W. A. Coventry* of Duluth, and *Dr. W. L. Burnap* of Fergus Falls, alternate to Doctor Braasch, were nominated to succeed themselves. It was moved, seconded and carried in each case that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for each.

Dr. Joel Hultkrans of Minneapolis was nominated to succeed Dr. George Earl as *alternate* to Doctor Coventry and it was moved, seconded and carried that the nominations be closed and that the secretary be instructed to cast a unanimous ballot for Doctor Hultkrans for the position of alternate to Doctor Coventry.

PLACE OF MEETING

Invitations from the Hennepin County Medical Society from Dr. J. M. Hayes of Minneapolis, president of the Minnesota State Medical Association, and from the Minneapolis Civic and Commerce Association to the Minnesota State Medical Association to hold its 86th Annual Meeting in Minneapolis were presented by Dr. C. A. Stewart, councilor of the sixth district.

It was unanimously voted to hold the 86th Annual Meeting in Minneapolis.

* * *

In the absence of Dr. A. J. Chesley, secretary and executive officer of the State Board of Health, Doctor Adson was asked by the speaker to give a report of the morning meeting of the State Board of Health.

Doctor Adson: I am sorry, Mr. Speaker, that Doctor Chesley is not here to give you the details of the meeting. The chief subject under discussion was the additional federal appropriation for control and treatment of syphilis which will be put at the disposal of the State Board of Health. I haven't the figures with me but I believe the amount is approximately $42,000. No great expansion in the work of the board can be carried on, as you know, until the present building program is completed. After that, it is the plan to add two assistants (clerks and technicians) with the intentions of using the money only to advance the present program.

Those of you who heard Doctor Irvine today fully appreciate the fine program carried on in Minnesota by the State Board of Health and also the fine interest and coöperation of the board with organized medicine. The fact that the State Board of Health is willing to coöperate with us and to listen to the problems that confront us in the practice of medicine is one of the finest compliments that can be paid them. It is our hope that the medical men in the rural communities particularly will likewise coöperate with the board in its work.

It has been proposed that the new funds be used in some instances to assist those who have no money so that the doctor can be compensated for his work in the treatment of syphilis. At the present time, it is not the intention, as I understand it, to set up any additional clinics anywhere in the state for treatment of syphilis. Instead, the facilities already in existence will be utilized and the general lines of the program that has been in existence here for some twenty years will be followed. Perhaps, Doctor Braasch has something to add on this subject.

Doctor Braasch: I don't know whether we all appreciate what a valuable man Doctor Chesley is in this community. He is president of the national association of health officers and undoubtedly the outstanding man in the departments of health of the country today. He has received many offers to go to other branches but has elected to remain here. And his work in maternal and child welfare and in child health, as shown by the statistics, is a record in itself. If you visit the State Board of Health exhibit in one of the booths at this meeting you will see what progress has been made in this state.

Furthermore, Doctor Chesley has coöperated fully with the medical profession here and has worked for our joint interests in Washington. I think it no more than right that this House of Delegates should extend a vote of confidence and thanks to him for his work in our behalf and on behalf of the public welfare.

Doctor Sweetser: In seconding this motion, I would like to mention the fact, as chairman of the Committee on State Health Relations, that Doctor Chesley has invited a member of our committee to each Board of Health meeting since the formation of the committee. He has worked hand in hand with our committee all of the time.

The vote of thanks was unanimously carried by the House of Delegates and the meeting adjourned.

DOCTOR

If collection service and efficiency means anything to you, it should be interesting to know that in opening our St. Cloud office during the last thirty days, we have a balanced service with eight branch offices located at strategic points throughout the state.

YOUR ACCOUNTS ARE DEPRECIATING EACH DAY THEY ARE NEGLECTED!

We are ready to open additional offices in any locality where the volume of business would warrant its maintenance. This is the only professional organization in the state rendering a state-wide personal call service.

THE CROPS ARE HERE AND GONE. HAVE YOU YOUR MONEY?

For prompt and efficient personal call service, communicate with any of the following offices and our representative will gladly furnish you with any and all information necessary for you to make a definitely permanent connection with a company worthy of your business.

THE INFLUENCE OF AGE-DETERMINED FACTORS ON THE DEVELOPMENT OF TUBERCULOSIS*

ARNOLD RICE RICH, M.D.

Associate Professor of Pathology and Bacteriology, The Johns Hopkins Medical School

Baltimore, Maryland

IT IS now well known that at different periods of the life span there are striking differences in the clinical manifestations, the prognosis, the character of the lesions, the mortality rate and the epidemiology of tuberculosis.

The recognition of the existence of these age-period differences has become essential for the proper interpretation of the disease, whether by the clinician, the pathologist or the epidemiologist. For the proper understanding, and for the most effective control of the disease it is of great importance that we learn precisely to what these age-period peculiarities are due. Unfortunately, our information about this matter is sadly deficient at present. The problem is a large one, with many ramifications; and each particular age-period is sufficiently complex to warrant an extended discussion of the factors peculiar to it. I cannot hope, therefore, to do justice to the consideration of all of the different age periods in a single lecture; but it may be worth while to attempt a review of the situation, even though no other end is achieved than that of defining and emphasizing the rather narrow limits of our present information regarding this important and arresting subject.

One of the most fundamental questions involved in the problem, and one that has aroused much interest and speculation, is that relating to the degree of native resistance to tuberculosis possessed by the human body at the different periods of life. By "native resistance" we mean, of course, the inherent ability of the body to destroy or to prevent the progressive proliferation of the bacillus on first contact with it. Is this inherent ability different at different periods of life, independently of external circumstances? Throughout the following discussion we shall pay particular attention to this question.

The characteristic and consistent differences in the tuberculosis mortality rate at the different periods of life have been regarded by many as sufficient evidence that there are corresponding differences in native resistance at the various age periods. Simple mortality rates, however, do not in themselves throw any certain light upon differences in native resistance, for they are influenced too greatly by the complicating factor of resistance acquired through previous infection, by the external influences that are peculiar to each age period and which exert a potent effect upon resistance, and, most important, by the incidence of infection in the population at the different age periods. Resistance is the ability to restrain the progress of infection. In a consideration of resistance at a given age period, therefore, we are interested not in the number of deaths in relation to the total number of individuals of that age (i.e., the general mortality rate), but only in the number of deaths in relation to the *infected* portion of that age group. In other words, the only figures of any suggestive import in relation to resistance are those which tell us whether a larger or a smaller proportion of the *infected* population in a given age period die from the disease, as

*The John W. Bell Tuberculosis Lecture, delivered before the Hennepin County Medical Society, Minneapolis, Minn., April 4, 1938.

*White subjects only.

compared with the mortality rate of the infected population in a different period of life. It is this relationship that we shall first proceed to examine.

At the very outset of this enquiry we encounter the first of our many difficulties and uncertainties, in the circumstance that no accurate information exists regarding the incidence of infection in the different age groups of the population at the present time. There are no recent representative autopsy studies of the matter, and no sufficient number of properly carried out and properly distributed tuberculin surveys made since 1930; and in the face of the rapidly declining tuberculosis mortality, figures for some years back cannot with propriety be mixed with the more recent ones.

In Table I, I have assembled the results of twenty representative tuberculin surveys reported in this country since 1930. The gaps in the available material are impressively evident. Particularly is there a dearth of representative material relating to adults, for the figures for college students can hardly be regarded as a fair average of the population. In the past, when it seemed established that the great majority of adults were infected, the position was adopted that nothing profitable could be learned from further tuberculin-testing of adults, and it became the practice to concentrate attention upon the incidence of infection in children. This attitude has persisted up to the present. In view of the markedly altered mortality rate of today, however, it becomes highly desirable that both rural and urban surveys of the incidence of infection in adults of all ages be undertaken again, and on a country-wide scale.

Studies of the incidence of infection in the first year of life are also urgently needed. At present there are only fragmentary figures on unrepresentative material, so that any estimate of the present day incidence of infection in the first year must represent only an individual guess.

In attempting to form an opinion regarding the incidence of infection from tuberculin surveys, there arises the important question as to the frequency with which a negative test may occur in persons who have been previously infected. It is commonly assumed that only in exceptional cases will the test be negative in healthy persons who have been previously infected, if 1.0 mg. of Old Tuberculin be used. Certainly, in the past, our information tended to support that view, but in the face of the markedly changed conditions it becomes possible that the results of the tuberculin test in present day surveys no longer mirror so well the actual incidence of infection. One disturbing element is that we do not know the average duration of tuberculin sensitiveness following a slight, well-resisted infection, and this clearly is a matter of importance in the interpretation of the results of tuberculin tests in terms of incidence of infection.

That hypersensitivity, once established, by no means invariably remains at a level detectable by the routine tests has long been well known. This was plainly shown by Austrian[4] fifteen years ago, and all investigators who have studied the matter thoroughly are agreed on this, though there are differences of opinion as to the usual duration of manifest hypersensitivity, and the frequency with which it falls to a level too low to be detected by the routine tests. Evidence is rapidly accumulating, however, which leaves no doubt that hypersensitivity to tuberculin may be lost with a frequency which, under present conditions of infection, has to be seriously considered in any evaluation of the results of tuberculin surveys. To make this clear it will suffice to call attention to a number of recent studies, all carried out by experienced and able investigators. Barnard, Amberson and Loew[5] found that of 184 school children between twelve and fifteen years of age who had tuberculous lesions demonstrable by x-ray, 6 per cent failed to react to 1.0 mg. of Old Tuberculin. Wells and Smith[53] found demonstrable x-ray lesions in 5.5 per cent of 128 individuals negative to 1.0 mg. of tuberculin. The careful studies of Opie and his associates[25,38] on children between five and nineteen years showed that 15 per cent of 186 who were negative to 1.0 mg. of tuberculin had definite x-ray evidence of tuberculous infection. Crabtree, Hickerson and Hickerson[15] have recently reported a study in persons over four years of age who were negative to 1.0 mg. of carefully standardized tuberculin. Seventeen per cent of those tuberculin-negative individuals were found to have calcified lesions on x-ray examination. Dr. Gauld, of the Department of Epidemiology in the Johns Hopkins School of Public Health, has recently shown me the results of an extensive study, soon to be published, in which an even higher percentage of definite calcified lesions in the lungs and bronchial nodes was found in healthy individuals completely negative to 1.0 mg. of carefully standardized Old Tuberculin; and Nelson, Mitchell and Brown[36] have recently reported similar results.

Since it is well known that the x-ray reveals the primary lesion in only a small percentage of all who do react to tuberculin and are therefore known to be infected, it is clear that the total number of infected persons among those who fail to react must be much larger that the number discovered by x-ray in the above-mentioned studies.

It can hardly be objected that the x-ray interpretation of all of these experienced students of tuberculosis were erroneous, and that the lesions observed in their tuberculin negative subjects were not really tuberculous. As a matter of fact, I know that in Dr. Gauld's study the figures for the presence of calcified tuberculous lesions in negative reactors were so high that he had the plates checked by four independent specialists in different cities in order to rule out errors of individual interpretation. But even such a possible objection is met by investigations in which the change from the hypersensitive to the tuberculin negative state has been directly observed. Thus, Lloyd and MacPherson[30] report from England that of 303 healthy London children who reacted to 1.0 mg. of Old Tuberculin in 1930, 2 per cent were negative to that dose two years later; and Aronson,[2] who has had so extensive an experience in tuberculin surveys in this country, has followed eighty-seven tuberculin-positive urban children for a period of five years, during which time 9 per cent became negative to 1.0 mg. of carefully standardized Old Tuberculin. In a private school that was free from cases of open tuberculosis, Horan,[27] tested 197 adolescent boys yearly for three successive years. During this time 14 per cent of those who were tuberculin-positive on the first test had lost their hyper-

sensitivity to 1.0 mg. of tuberculin. In a recent study, Paretsky[41] reports that out of a group of tuberculin-positive children that were followed up to five years, 80 became negative to 1.0 mg. of Old Tuberculin. Sixty-four per cent of these were retested with 10.0 mg. and failed to react. In animals remaining in good health after having resisted a tuberculous infection, hypersensitivity may fall to so low a level after the lapse of one to two years following infection, that very large doses of tuberculin fail to produce any reaction; and it is very important to remember in relation to the human being that it has been demonstrated by Willis[54] that the animals that lose their sensitivity with the passing of time retain in high degree the resistance to reinfection that was conferred by the original infection. Sewall and his co-workers[47] and Boquet[7] have likewise shown that as hypersensitivity declines acquired resistance remains intact; and numerous studies from our own laboratory, confirmed by many subsequent investigations, have demonstrated that when hypersensitivity is deliberately abolished by proper desensitizing procedures, immunity to reinfection remains in high degree.[44] In the human being, therefore, not only is a negative tuberculin test no proof that the individual has never been infected, but it is also no proof that acquired resistance is lacking.

These considerations obviously have an important bearing upon the proper interpretation of the results of tuberculin surveys. In the first part of this century, when the mortality and morbidity from tuberculosis were very high, and open cases were far more numerous in the population than they are today, individuals who became infected once had a greater opportunity to become infected again and again throughout their lives, and so to have their hypersensitiveness frequently restimulated. Today, however, the spectacular decline in mortality and morbidity (and, therefore, in the number of open cases) has greatly decreased the opportunities for chance contact with the bacillus. The marked diminution in the number of open cases must influence not only the total number of individuals who will become infected at each age period, but also the number and frequency of repeated reinfections. Under these conditions it is reasonable to believe that a correspondingly larger number of individuals in the population today are escaping the hypersensitivity—reanimating influence of reinfections after having lost the sensitivity conferred by a primary infection. It cannot be assumed, therefore, that the number who fail to react to tuberculin in a given survey in this country today approximates the number who have never been infected as closely as may have been the case in the early part of this century.

It is highly desirable to learn to what degree any present day diminution in the number of positive reactors reflects an actual decline in the number of primary infections, and to what degree it is due to a lessened opportunity for reinfections which maintain hypersensitivity at a level detectable by the routine tests. Large scale minute studies of the incidence of primary infections and reinfections in routine autopsies, such as those that were carried out some years ago during the period in which the opportunities for infection were much greater, are urgently needed in order that we may gain a better insight into the actual present-day incidence of infection in the different age groups.

In order to make clear how badly such studies are needed, I shall only remind you that for many years throughout the world it has been regarded as an established fact that the so-called adult type of pulmonary tuberculosis, characterized by apical or sub-apical localization, prominent fibrosis, the failure to involve regional lymph nodes appreciably, and by little tendency to generalization, develops only as a result of *reinfection* in persons who previously have had a partially immunizing, primary infection; and that if progressive disease develops directly as a result of *primary* infection, it will have the characteristics familiar in progressive childhood tuberculosis, namely, localization anywhere in the lung with the apex as the least frequent site, prominent caseation and little fibrosis, marked involvement of regional lymph nodes, and marked tendency to generalization. Now there is much experimental, clinical and pathological evidence in support of this deep-rooted belief, and as long as practically all individuals in urban communities were known to have had a primary infection by the time adult life was reached there was little to disturb that view. At present, however, we are told, on the basis of tuberculin surveys, that only about half of all young adults carry a primary infection. If this be true, and if our long-held attitude toward the adult and childhood type of tuberculosis be correct, we should today be encountering on all sides, both

TABLE II.

*Estimated from recent tuberculin surveys. The figures for some of the age periods are probably too low. See text for question of reliability of tuberculin surveys as indicators of the true incidence of infection.

clinically and pathologically, many instances of progressive tuberculosis of the childhood type developing in the great number of young adults who, according to the tuberculin surveys, have never had a previous, immunizing infection. This, however, is not the case. Young adult tuberculosis, both at the bedside and at the autopsy table, has today precisely the same characteristics as that during the period when primary infection in urban adults was almost universal. In this connection it is of particular interest to note that in the recent study carried out by Myers and his co-workers[33] on tuberculous infection developing in young adults who were regarded as never having been previously infected because they were negative to tuberculin shortly before the lesions appeared, in the overwhelming majority of those cases the lesions were apical or sub-apical and were typical of the adult type of the disease. Were these, then, really instances of primary infection, or were they instances of reinfection in individuals who had lost their hypersensitivity? This question has to be considered the more seriously since Arborelius[1] has described cases of apparently true primary infection occurring in tuberculin-negative young adults from rural districts in Sweden, and in those cases the lesions were never apical but were typical of those characteristic of primary infection in childhood; and instances of typical, progressive childhood-type tuberculosis in young adults were observed at autopsy by Hart[24] in the German army during the World War.

These circumstances should make it clear that either our long-held concept of the pathogenesis of adult type tuberculosis requires a drastic revision, or else that many individuals who today are tuberculin negative have really been infected, and have retained their acquired resistance to the degree that determines the peculiarities of adult type tuberculosis, but have lost their hypersensitivity, and under present conditions of diminished opportunity for reinfection they remain tuberculin negative for longer periods than would have been the case formerly. Only a minute search for healed lesions with the aid of the x-ray in routine autopsies can settle this matter, and studies of this nature are at present being carried out in Baltimore. Needless to say, similar studies should be undertaken in widely different parts of the country, in order that a representative survey may be possible.

In order to determine the mortality in the in-

fected portion of the population at each age period it is necessary to be able to compare the total deaths from tuberculosis in the entire population at a given age period with the number of infected persons in that age period. In view of the above circumstances it is obviously impossible to pretend to deal with any degree of accuracy with the question of the country's "average" incidence of infection at the different age periods. One can only form an individual impression of the matter from a study of the available urban and rural tuberculin surveys, making allowances for the circumstances discussed; and it is hardly to be expected that there will be any general agreement among the individual impressions so formed. It is such an impression, and no more than that, that is given in Table II. The estimate of the incidence of the infection for each age period has been made as conservative as has seemed compatible with present-day information, and it is probably too low in certain instances. In the older age groups we still have to do with individuals who have had to pass through the period of high exposure risk of the latter part of the last and the early part of the present century, and we cannot expect the incidence of infection in those individuals to reflect as well the more recent lowering of exposure risk.

While the figures in Table II relating to the proportion of infected persons in the population at each age period are admittedly based upon data that leave much to be desired, they nevertheless provide at least a relative view of the situation as it exists today, and it is important to make an attempt to view it from this particular standpoint. Certainly, any correction of the figures for the incidence of infection in any of the age periods within limits that, in either direction, are within range of probability, would not alter appreciably the general trend that the figures express. The figures showing the mortality rate of the infected portion of the population are markedly different from the ordinary mortality rates of the total population, and they bring out more clearly than do the latter figures the following facts which have been recognized by clinicians and students of the epidemiology of tuberculosis:

1. That tuberculosis is most fatal during the first year of life;

2. That it is much less dangerous, but still markedly so during the succeeding several years;

3. That the period between five years and puberty is a strikingly "safe" period, during which the mortality from the disease decreases in spite of the fact that the incidence of infection increases. In this period of life the tuberculosis mortality rate reaches its lowest point.

4. That following the age of puberty there occurs a sharp increase in the death-hazard among those infected.

5. That the increase in the tuberculosis mortality-hazard continues steadily into adult life, reaching a peak in the middle twenties, after which it continues at an elevated level throughout the remainder of the life span, but with variations that depend upon sex, occupation and economic conditions.

6. That in old age there occurs a second peak of mortality-hazard.

From the above facts it is clear, then, that by far the most dangerous age period in which to be infected, from the standpoint of the chance of succumbing during that age period, is that of the first five years of life, and most particularly during the first year; and that by far the safest period is that between five years and puberty. From puberty onward the chance of dying if infected increases rapidly until it reaches a peak, the precise age period of which is inconstant in the total population and may be different for each sex at different periods of time. The mortality rate among the infected is always high in old age, but it may be lower than the first adult peak. How are these age peculiarities to be explained, and what relation, if any, do they bear to age-determined differences in native resistance?

Factors Influencing the High Mortality in Infancy

Regarding the extraordinarily high mortality among those who become infected during the first year of life, it is altogether probable that this is due in part to the fact that since infants cannot move about to court infection they are ordinarily exposed either to heavy and continued infection (phthisical member of the household; contaminated milk, in localities in which bovine tuberculosis is prevalent) or to none at all. This explanation was suggested long ago by Römer,[46] and it is a reasonable one. In addition, it may be suggested that since

malnutrition affects resistance to tuberculosis adversely at all ages, the frequency of nutritional disturbances in infancy may play a rôle in favoring progressive infection in this period. In infancy, as is well known, malnutrition frequently results from conditions other than an insufficient supply of food in the home. High atmospheric temperature, artificial feeding, and acute infections of even slight degree, such as otitis media, are factors which often precipitate a diarrhea that prevents the proper assimilation of food, with consequent malnutrition not infrequently of severe degree. After the first year, debilitating diarrhea occurs less frequently as a complication of these conditions. It is not altogether improbable, therefore, that the greater frequency of malnutrition during the first year may influence to some degree the chance of development of progressive tuberculosis among those who become infected during this period of life.

But these factors of dosage of bacilli and liability to malnutrition do not dispose of the possibility that, in addition, the native resistance of the healthy infant may be lower than that of the older child or adult. Is there any reason to believe that this may be the case?

There is not at present any actual *proof* that the infant has a lower native resistance to tuberculosis than have older individuals. Obviously, it is practically impossible to obtain direct and controlled evidence regarding the degree of native resistance in the human being, for the only way in which the effectiveness of the mechanism of immunity can be accurately determined is by observing the result of a standardized test infection. Neither the clinical nor the pathological aspects of the accidentally acquired disease can help us here, for none of the variables, including the important one of dosage, are controlled.

If we turn to animal experiment for an answer to the question we find that while it has often been demonstrated clearly that young animals are more susceptible to many acute infections than are adult animals, the several experiments which have so far been carried out on tuberculosis have failed to show any convincing differences between the resistance of young and older animals. It may be fairly said, however, that none of the few recorded experiments on this subject are sufficiently satisfying to be regarded as at all conclusive.

Nevertheless, there is evidence from a different direction which, it has seemed to me,[45] can profitably be applied to the problem under consideration, and which renders it altogether likely that the native resistance of the infant to tuberculosis may be lower than that of the older individual. It is essential to bear clearly in mind the fact that any consideration of *native* immunity in a chronic disease involves, inescapably, a consideration of *acquired* immunity. In an acute infection which rapidly runs its course to a fatal termination, native immunity can be studied uncomplicated by acquired immunity, although even here this is true only when an infecting dose is chosen which will not permit survival for more than a day or two. Even in an acute infection, antibody-formation will be initiated as soon as the bacteria have multiplied to numbers sufficient to liberate an appreciable amount of antigen. It is well known, for example, that antibody-formation is often demonstrable a few days after the onset of lobar pneumonia in the human being. When protective antibody has begun to appear, acquired resistance has, of course, already entered the picture. In a chronic infection, in which the bacteria multiply in the body for weeks and months, it is clear that acquired resistance resulting from the infection itself will always have developed to some degree before the disease has run its course. This is strikingly true of tuberculosis. There is unassailable evidence that during the course of primary infection, in both the human being and the experimental animal, acquired resistance usually appears to a very definite degree, even in the case of infections that result fatally. The degree to which acquired resistance develops during infection, and the rapidity of its appearance, are important factors in the progress of the disease; and in many cases in the human being this factor of acquired resistance undoubtedly plays a dominant rôle in determining whether the infection will be restrained and arrested or whether it will progress to a fatal termination. In tuberculosis, therefore, it is essential to consider whether an observed degree of resistance to a primary infection is due chiefly to natively existing elements of immunity, or to circumstances that influence the degree to which acquired immunity develops following infection, and the rapidity with which it makes its appearance. Since this is the case, it is obvious that if the mechanism for devel-

oping acquired immunity were less efficient in infancy than in later life, the infant would unfailingly be less able to resist infection than the older child or the adult. Is there, then, any evidence that this situation actually exists?

Up to the present no satisfactorily controlled experiments dealing with the comparative ability of very young and older animals to develop acquired resistance to the tubercle bacillus have been carried out. There is, nevertheless, important evidence that the immunity response of human infants and very young animals to other bacteria and antigens is much less efficient than that of older individuals of the same species. Freund,[20] Kligler and Olitzki[29] and others have shown that very young animals cannot form antibodies to bacteria, bacterial toxins or foreign proteins nearly so effectively as older animals. This is true of birds as well as of mammals; and it is likewise true of the human being. It has been shown by Halber and his collaborators[23] and others that the human infant is deficient in the ability to form agglutinins in comparison with older children; and Ramon and his collaborators[35] and others have shown that the infant is distinctly less able to form diphtheria antitoxin than is the adult. Davies[17] found that infants in the first year of life failed to produce protective antibody in response to the injection of a pneumococcal antigen that was highly effective in stimulating the formation of protective antibody in older individuals, and Dr. Lloyd Felton, of our department, in a recently completed study, has had the same experience.

In connection with the evidence that infants cannot form antibody as effectively as older individuals, it may be stated that we have recently shown experimentally that the acute splenic tumor of bacterial infections represents a reaction to foreign antigens, and can be readily produced by introducing into the tissues foreign protein, whether of bacterial or non-bacterial origin.[43] It is of interest, therefore, that in infants acute splenic tumor rarely becomes so well developed during infection as it does in adults.

The fact that infants are relatively deficient in the ability to form protective antibodies as compared with adults has an important bearing upon the problem before us; for regardless of the lack of absolute parallelism between antibody titre in tuberculosis as measured by present *in vitro* tests, and resistance to infection as measured by the body's ability to restrain the growth and spread of the bacilli, it is altogether likely that antibody-formation plays an important rôle in immunity to tuberculosis, as it does in immunity to other infections, even though the rôle that it plays in tuberculosis is not yet manifest in all of its relations. It must be remembered that there is no strict and constant parallelism between the serum antibody titre and resistance to infection even in the case of infections in which antibody is well known to play a highly important rôle in a defense. Time does not permit me to enter into a discussion of the function of antibody in resistance to tuberculosis. Here, I wish only to recall to you the fact that infants and young animals have been shown to be natively deficient in the ability to develop acquired immunity and to produce protective antibodies of every type so far investigated, and to point out the reasons for believing that a deficiency of this nature can play an important rôle in determining the well recognized greater susceptibility of the infant to primary tuberculous infection.

It is of interest in this connection that the deficiency in antibody-formation has been found to be particularly striking in infants under six months of age, and Brailey,[10] in the out-patient clinic of the Johns Hopkins Hospital, has found that the mortality from tuberculosis was more than twice as high in infants known to have been infected during the first six months of life as in those whose infection was first discovered between the ages of six months and two years.

Until more evidence is accumulated, we cannot speak with absolute certainty of the rôle that specific age susceptibility may play in the higher tuberculosis mortality rate of infected infants. It is, however, difficult to believe that the infant, with a deficient immunity-producing mechanism, can be natively as resistant to infection as the older child or adult with their more effective immunity mechanism; for in tuberculosis, the rapidity with which an effective degree of acquired resistance develops following infection plays a very important rôle in determining the outcome of a primary infection. Indeed, the well known fact that other infections (e.g., whooping cough, measles, chicken-pox, scarlet fever, diphtheria, pneumococcal, staphylococcal infections, et cetera) are much more fatal in young infants than in older

children, is, in itself, evidence that the native ability of the infant to resist infections in general is deficient (Table III).

TABLE III

Figures for the Last U. S. Census Year (1930)

Age	Deaths Per 100,000	
	Combined Infections	Lobar Pneumonia
0-4	255	56
5-14	47	8
15-24	106	15
25-34	129	23
35-44	126	32
45-54	142	56
55-64	165	90
65-74	223	166

With no intent to disparage the investigation of the possibility of protective immunization by means of BCG or vaccines made of killed bacilli, which most assuredly should be studied until their potentialities and limitations are soundly established, it may nevertheless be pointed out that in administering these immunizing agents to new-born infants, as is ordinarily practiced, they are being applied to subjects who, in the light of all available evidence, have far less power of reacting to immunizing antigens than have individuals at any other period of life. This should be taken into consideration not only in regard to the dosage and the period of immunization, but also in drawing conclusions as to the immunizing power of these vaccines from the results obtained in newborn infants. Used at a later period their efficacy would, in all probability, be much greater.

One final point deserves comment in relation to the matter under discussion. For a long period of time the high mortality of infants with *clinical* tuberculosis led to the universal belief that infection in infancy was practically invariably fatal. More recent follow-up studies of tuberculin-positive infants have shown plainly that this is not the case, and this point has been stressed by Myers[32] and others. However, even in the literature of recent years one may still encounter the statement that the newly-born infant is completely devoid of resistance. Gottstein,[22] in his recent excellent monograph on the epidemiology of tuberculosis, states that at least 80 per cent of all infants infected in the first year of life die of the disease. There are enough studies at present to make it clear that this is far from the case. In a recent follow-up study, Brailey,[10] in the Johns Hopkins Clinic, found that of sixty-six infants who became tuberculin-positive during the first year of life, two-thirds were alive and well at the end of the five years. Had it not been for a large admixture of negro infants in the series the survival rate would undoubtedly have been higher, for 82 per cent of the white infants survived the five-year period as contrasted with only 57 per cent of the negroes.

The Lübeck disaster of 1930 was, itself, highly instructive in this connection. In that unfortunate episode, as is well known, 251 newborn infants who were to have received prophylactic doses of the avirulent BCG bacillus, by mouth, were given by error cultures that were contaminated with virulent human type bacilli. Seventy-two of these children died with extensive tuberculosis within the first year, after which time there were no more deaths from tuberculosis. At the end of four years, when an extensive and minute official report was prepared,[18] it was found that 71 per cent of all of these children who had been infected with presumably large doses of virulent bacilli in the first few days of life were alive with no clinically active lesions, though the presence of arrested calcified lesions, often extraordinary in extent, was demonstrable in most of them. It is, therefore, obvious that it is by no means true that the infant is "completely devoid of resistance." On the contrary, in spite of the very high mortality among infected infants as compared with older individuals, and while there are very good reasons, given above, for believing that the native resistance of the infant is decidedly lower than that of the older child, a large majority of those infected in infancy are able to resist the infection.

Factors Influencing the Mortality Rate Between One and Five Years of Age

During the second year of life the external influences which act in infancy to favor a high death rate among those who become infected with the tubercle bacillus are still operative to some degree. The free excursion of the child into the outside world is still restricted and, as in the case of the infant, though to a lesser degree than during the first year, the most frequent source of infection will still be a phthisi-

cal member of the household or contaminated milk, with the opportunity for heavy and repeated infection inherent in these sources. However, the more independent locomotion of the child at this age increases somewhat its chances of acquiring slight first infections, particularly among the poorer classes. Nutritional disturbances due to diarrhea are less frequent than during the first year but are still fairly common and may serve to depress resistance in a portion of those who become infected with the tubercle bacillus. On the other hand, the ability to develop immune antibodies is distinctly higher in the second year than during the first six months of life, though not yet quite so well developed as in later childhood. These various factors all tend to bring it about that the mortality among those infected during the second year, though still high, is nevertheless much lower than that among those infected during the first year. In Brailey's study mentioned above,[10] the mortality of children who were first found to be tuberculin-positive in their second year was far lower than those in whom infection was discovered during the first six months of life.

After the second year of life the death rate of those who become infected falls markedly. It is reasonable to believe that this is due, in part at least, to the fact that the ability to move freely outside the home is accompanied by the opportunity for acquiring single, slight infections which can be well resisted, in contrast to the situation that obtains during the first two years. In addition, it is pertinent to point out that children between two and five years of age have a decidedly greater ability to form immune antibodies than have infants.[23]

Factors Contributing to the Low Mortality Rate Between Five Years and Puberty

The tuberculosis mortality rate among the infected population in the decade between five years and puberty is markedly lower than that in any other decade of the life span (Table II). The reasons for the low death rate in this period are certainly not all clearly understood at present, but there are at least several circumstances which may be regarded as playing a rôle in this direction.

In the first place, while there is ample evidence from tuberculin tests and autopsy studies that free movement in the outside world during this period is accompanied by a great increase in primary infections, far fewer of these infections produce progressive, fatal disease than in infancy. We may assume, therefore, that a smaller percentage of the infections acquired during this decade are dependent upon heavy and continued exposure in the home, and that a much larger percentage represent the results of single, chance contacts in the outside world leading to slight infections which can be successfully resisted.

This decade is the one during which the individual, exposed freely to contact with the outside world, is most protected against the vicissitudes of life. These are years during which most children are protected in the home and in school, and during which they are, in general, spared from the cares, stresses, strains, debilitating influences and occupational hazards of later life. They have ample time for invigorating play out of doors, and have little to interfere with needed rest or regular and sufficient sleep. Many of the known factors which tend to depress resistance to tuberculosis are, therefore, in abeyance during this decade.

In addition, there is very good evidence that during this period of life the mechanism for developing acquired resistance (so-called "serological maturity") becomes fully established. It was pointed out above that infants and very young animals have a deficient immunity mechanism, and it is interesting to note that at the various periods of life there is a definite correlation between the titre of natural agglutinins, as exemplified by the blood groups, and the power to form antibodies against bacteria and their products. Thus, the new-born infant's deficient antibody-producing power is paralleled by the fact that the isoagglutinins that determine the blood groups are rarely present at birth. In general, the isoagglutinin titre is quite low and in some instances still zero between six months and one year of age; from one to two years, parallel with the increase in antibody-producing power, the isoagglutinin titre rises; and it reaches its height precisely during the period under present discussion, namely, between five and ten years of age.[51] There is no evidence that after this period of life any further increase occurs either in isoagglutinin titre or in immune antibody-forming power.

While there are probably other and as yet undetermined factors, it is reasonable to believe that the above circumstances play a significant

rôle in determining the lower tuberculosis mortality rate during this period of life, which is one of amazing safety as regards most infections, as can be readily seen in Table III. The careful study of the reasons for these marked differences in the mortality from various infections in the different age periods is clearly of the greatest importance for preventive medicine and public health.

Factors Influencing the Rise in Mortality Rate in Adolescence

The close relationship between the age at which the tuberculosis mortality curve begins to rise sharply and the period at which the puberty readjustments of the body take place, suggests at once that the state of pubescence may be accompanied by a depression in resistance to the infection, and that we are faced here with an age-period determined level of resistance. While no absolute proof of this exists at present there are circumstances which render it altogether probable.

In the first place, while the mortality rise at puberty and during adolescence can be accounted for partly by the fact that the freer excursion into the outside world at this period is accompanied by an increase in the opportunities for contact with open cases, it is perfectly clear that this factor alone is insufficient to account for the phenomenon. The increase in mortality far outstrips the increase in infection, and this is true regardless of what tuberculin surveys are used for the estimation of the incidence of infection. Furthermore, we have already seen that in the period between five years and puberty a great increase in incidence of infection is actually accompanied by a decrease in mortality—a fact which stresses the importance of factors other than mere infection incidence in the determination of the relative mortality rate of the different periods of life.

That a certain amount of active tuberculosis appearing at this period represents the evolution of infections acquired earlier in life cannot be questioned, but there is no reason for believing that this increment is great enough to account for the observed abrupt mortality rise unless we assume at the same time that resistance becomes depressed at this period, and so permits a greater number of infections to undergo progression than would have done so had resistance not flagged.

For a better understanding of the level of native resistance at the different periods of life after childhood, we need to know much more about the ultimate fate of those who become infected for the first time at each age period. Superficial studies of this matter, which ignore factors such as family contact, economic status, etc., can be very misleading. In time, the careful, long-period method of individual family study of the type now being carried out in various cities will provide invaluable information regarding the question. In relation to the matter before us, we may cite a study carried out by Opie and McPhedran[39] on persons living in contact with open tuberculosis and followed for a period of ten to fourteen years after the beginning of exposure. Of those first exposed between birth and nine years of age, 9.9 per cent developed clinical tuberculosis; but of those first exposed between ten and fourteen years of age, 20 per cent developed the disease. In this particular study, exposure to familial infection in the unstable period immediately preceding and at the time of puberty was twice as dangerous as was exposure prior or subsequent to this period.

It may further be noted that while the tuberculosis mortality-rise following the low mortality period of childhood is marked in males, it occurs at a somewhat earlier age and is more pronounced in females. In females, the puberty alterations likewise occur earlier and are more profound than in males. Since there is no significant difference between the incidence of infection in males and females at this period of life these facts, in themselves, are highly suggestive that the state of pubescence plays a rôle in altering the resistance of the individual.

Suggestive evidence of the relation of pubescence to resistance is also provided by clinical and pathological experience. From the clinical side it has long been recognized that the period of pubescence is accompanied by a tendency to the exacerbation of latent lesions and the more rapid progression of active ones, and that this danger tends to be more pronounced in the female. On the pathological side it is familiar that progressive lesions of reinfection which develop at this period of life frequently have characteristics which are not encountered in typical white adult reinfections—features which indicate a higher degree of resistance than that seen in progressive first infections of childhood,

but a lower degree of resistance than that in adult reinfections. It is not uncommon, for example, to find in this age-period progressive apical lesions quite like those that are characteristic of adult tuberculosis, though often with rather more prominent caseation and rather less prominent fibrosis; but associated with this type of pulmonary lesion there may be enlarged, caseous peribronchial lymph nodes—a finding that is foreign to typical adult tuberculosis, but is the rule in the progressive tuberculosis of the non-immunized child. In most instances the enlarged lymph nodes are not completely caseous, as they so frequently are in progressive tuberculosis of the young child, but show instead rather large areas of caseation embedded in non-necrotic node tissue. It may be recalled that the adult negro has a tendency to develop precisely this type of the disease on reinfection, and there is very good evidence, which I have assembled elsewhere[45] and which time prevents reviewing here, that the negro's level of native resistance is definitely lower than that of the white, and that dosage and living conditions are altogether inadequate to explain the differences in disease in the two races.

In precisely what manner pubescence acts to influence resistance to tuberculosis, as it apparently does, is at present obscure. The problem hardly lends itself to direct experimental investigation, for the period of pubescence in laboratory animals is of such brief duration. In the attempt to eliminate sexual factors, several investigators[9,13,16,31] have studied the effects of tuberculous infection in castrated animals, but the results have been contradictory.

Approaching the problem from the opposite angle, Vercesi and Merenda[52] and Repetti[42] found that an excess of the female hormone had no effect upon native resistance to tuberculosis in experimental animals; and Dr. L. A. Gray and Dr. C. B. Brack, in our laboratory, have recently shown that acquired resistance is likewise unaffected in animals kept continually in a state of hyperoestrinism. Furthermore, Gray and Brack, in carefully controlled experiments, have so far been unable to confirm the recent report of Steinbach and Klein[49] that antuitrin increases resistance to the experimental disease.

These experiments, of course, demonstrate no more than the failure of an excess of these two particular hormones to affect resistance under the experimental conditions. They neither reproduce the state of pubescence, nor invalidate the view that resistance in the human being is altered at this period of bodily readjustment.

In summary, the sharp rise in mortality that follows the childhood period of relative safety and continues into adult life is accompanied by clinical and pathological evidences of deficient resistance, and is associated with the following circumstances: (1) a progressive increase in the incidence of infection; (2) apparently a specific adverse effect of the state of pubescence on resistance; (3) the beginning of exposure to the stresses and strains associated with the struggle for existance and with childbearing. That other less evident factors may be operative cannot be denied. The most earnest study should be devoted to an elucidation of the factors which influence the development of progressive tuberculosis at this time of life, for the precise reasons for the disastrous effects observed during this period, and later in life as a result of infection at this period, are still for the most part obscure, and the problem is one not only of extraordinary theoretical interest, but of the utmost importance from the standpoint of human welfare.

The Relative Degree of Native Immunity in Adult Life

Following adolescence the tuberculosis mortality rate continues to rise steadily into adult life. The age period at which the peak of the rising curve is reached varies in different places and at different times, but except in communities where economic conditions and industrial hazards are particularly bad, the mortality peak is ordinarily reached in the middle twenties, and at a somewhat earlier age in the female than in the male.

The high mortality rate in the middle twenties is due in part to the rising incidence of infection, but the rate of increase in mortality definitely outstrips the rate of increase in infection-incidence. Other factors, therefore, undoubtedly play a dominant rôle in determining the rise in mortality rate at this period of life. The effects of general and specific occupational hazards, childbearing and the care of a family, and the pressure of the stresses and strains of the struggle for existence are now in full play. In addition, there is no doubt that many cases of tuberculosis having their inception during the suscept-

ible period of adolescence reach a fatal termination in young adult life and so add to the number of fatalities in this period.

Time does not permit me to enter into a discussion of the highly important problems involved in the effect of these various factors upon resistance to tuberculosis. Little is known of the manner in which most of them lower resistance. Even deleterious factors as familiar as malnutrition and physical exhaustion exert their adverse effects in a manner that is still almost completely obscure; and this is likewise true of those factors which at present can be expressed only in rather vague terms such as "over-stress and strain," and "the run-down state"; terms which, however unscientific, nevertheless express very real hazards in the body's struggle to hold a tuberculous infection in check.

I believe that there can be little doubt that childbearing plays a definite rôle in influencing the female mortality rate in the general population. Without questioning the fact that the danger of childbearing may be reduced to a minimum for many tuberculous women *if adequate care is provided before and after labor,* as the studies of Jennings, Mariette and Litzenberg[28] and of others plainly show, it is nevertheless beyond question that childbearing may be attended by a variety of circumstances which can affect tuberculosis adversely if adequate rest and care are *not* assured—and certainly they are not assured in the case of most tuberculous women who become pregnant. Among these adverse conditions I need only mention the physical exertion of carrying the fetus about in the latter months of pregnancy in the performance of the usual household tasks; the exhausting strain of labor; the loss of nutritive materials to the fetus and to the nursing infant, particularly in undernourished women; and the effort and broken sleep involved in caring for the infant after it is born, while the mother is still below par physically. All of these conditions contain factors that are well known to affect tuberculosis adversely, and it may be pointed out that the curve of female tuberculosis mortality bears an interesting relation to the frequency of childbirths at the different ages. At the end of the active reproductive period the female tuberculosis mortality falls sharply below that of the male. I have recently made an analysis of the relation of the female tuberculosis mortality to the birth rate and to certain other factors in the individual states of the Union, and, while other factors undoubtedly are highly important, it is at least interesting that there is a definite correlation between the birth rate among women past 30 and the length of the period during which the female tuberculosis mortality remains above that of the male in the individual states. When it is realized that each year in the United States approximately one out of every ten females between the ages of fifteen and thirty become pregnant, the opportunity for pregnancy to coincide with and to exert its deleterious effects upon tuberculosis in the female becomes impressively evident.

I cannot enter further into the various external factors that influence the development of tuberculsis in adult life but we must, for a moment, consider the question of the level of native resistance in young and middle aged adults, for this is a matter of considerable theoretical and practical import.

There are those who maintain that the previously uninfected adult is more susceptible to tuberculosis than is the child, and that it is dangerous, therefore, to adopt measures that will tend to postpone infection until adult life, particularly since an earlier resisted infection may confer some degree of acquired resistance upon the otherwise highly susceptible adult. Aschoff[3], for example, pleading this view, writes:

"We must, however, remember that with the prevention of the primary infection in childhood the adult is sent forth into life unprotected against this disease, which will then attack him with infinitely greater virulence than the usual familial infection, so to speak, in infancy."

This view that the adult has a lower native resistance than the child has many adherents. It has been based upon two facts: (1) that the tuberculosis mortality rate of young adults is much higher than that of young school children; and (2) that the adults of primitive African peoples in regions previously free from tuberculosis have developed a rapidly progressing type of disease with a very high mortality rate when tuberculosis was first introduced among them. The fear has therefore been entertained that if primary infection in childhood be prevented in our own communities, individuals who become infected in later life will fall victim to a similar devastating form of the dsease because they will lack the protection conferred by the acquired resistance that results from childhood primary infection.

In my opinion, there is no sound foundation for that view. In the first place, in transferring the observations on primitive races to civilized whites, no account is taken of the important evidence, to which I have already referred, that the native resistance of the negro is lower than that of the white race which has passed through centuries of contact with the tubercle bacillus. I have discussed our uncertainty regarding the significance of a negative tuberculin test, and it is a very real uncertainty; but, unless all present-day tuberculin surveys are completely misleading, there must now be a large number of individuals in the population who are being infected for the first time in adult life, and if white adults are really as susceptible as are the adults of primitive races we should at present be encountering on all sides cases of fulminant, primitive type tuberculosis in young white adults. In even the relatively small body of Senegalese troops brought into contact with tuberculosis apparently for the first time during the World War (only 5 per cent were tuberculin positive), devastating, rapidly progressing tuberculosis with caseation of regional lymph nodes and widespread generalization was soon impressively evident.[8] In the great group of tuberculin negative white adults at the present time, on the contrary, the development of this type of tuberculosis is extremely rare, and there is no evidence whatever to indicate that cases of this sort are any more frequent in adults than would be expected as a result of primary infection in a similar number of school children. Finally, it should be noted that there are no observations demonstrating that when tuberculosis is first introduced among natives living under primitive conditions the adults are any more severely affected than are the children.

In brief, the observations on tuberculosis in primitive peoples provides no justification whatever for assuming that the previously uninfected adult, whether white or negro, is any more susceptible, natively, than is the child of the same race.

Regarding the argument that the higher tuberculosis mortality among adults is evidence that adult *native* resistance is lower than that of children of school age, it is hardly necessary to point out that such a deduction is unwarranted, for it neglects entirely the important extraneous factors mentioned above which act to depress resistance in many adults, and from which the child is spared. In the face of such complicating influences, simple mortality rates provide no trustworthy gauge of the comparative degree of native resistance in adult and child.

If there is no acceptable evidence that adults have less native resistance than have children of primary school age, there is, on the other hand, no valid evidence that they are natively *more* resistant to primary infection, as some have assumed. This view that children have less resistance than adults has arisen partly from the failure to separate the highly susceptible first several years of life from the much more resistant primary school age, and partly from the observed tendency of progressive primary infection in childhood to spread throughout the body, in contrast to the more effective localization of the disease in adults. It neglects, however, the influence of resistance in the adult acquired by previous infection.

At present we possess insufficient information to permit us to speak with certainty about the relative level of resistance in previously uninfected adults as compared with children of the same race, and we shall remain unable to speak with accuracy about this important matter until we have more certain information regarding the frequency of *arrested* primary infection in adults, and the clinical and pathological manifestations of *progressive* primary disease in adults. I tend to believe, however, that the information that we do possess indicates that there is no significant difference between the child of primary school age and the healthy adult in native ability to resist a primary infection. The higher mortality from tuberculosis in adult life appears to be referrable to circumstances which depress resistance rather than to an innate, age-determined deficiency in native resistance. The influence which these external conditions exert upon tuberculosis mortality becomes particularly apparent in the fourth decade, for at this period the male tuberculosis mortality rate continues at a high level, whereas the female rate declines; and in parallel fashion, the industrial hazards to which males are exposed continue in full force, whereas the reproductive activity of females declines. Furthermore, the death rate of males at this period tends to be decidedly higher in urban and industrial centers than in rural communities—a tendency that is not shared by the females living under the same economic conditions, but largely

spared from the laboring hazards of the male (Table IV).

TABLE IV. DEATHS FROM TUBERCULOSIS

Per 100,000 White Individuals 30-35 Years of Age. 1932.

	Males	Females
Predominantly Rural States	62.6	73
Predominantly Urban States	86.2	75

Now even though there is at present no reason for believing that the normal adult has a lower *native* resistance than the child, we must not be misled into believing that infection carries no more risk for young adults in general than for children, for there is very definite evidence that it does. I do not think that any of the studies so far made which purport to show that primary infection carries no more of a hazard for young adults than for school children are sufficiently representative or extensive enough to permit us to accept that view. This is one of the situations upon which the figures for the mortality rate of the *infected* portion of the population throw important light, for they show clearly that the death rate among infected young adults is much higher than that of infected children of primary school age. Since the death rate of infected young adults is much higher than that of infected children it is obvious that *on the average* it is more dangerous to be an infected young adult than to be infected in the safe period of childhood. This is doubtless due in large part to the fact that the adverse circumstances discussed above, from which the child is ordinarily spared, often conspire to thwart the protective action of native and acquired resistance in adults. Even though native resistance, when unhampered, may be quite as good in adults as in children, since many more young adults are exposed to the conditions that affect tuberculosis adversely than are children of primary school age, it is reasonable to expect that primary infection in adult life will develop into progressive disease more frequently than in childhood.

It cannot with propriety be argued that the lower mortality rate of children as contrasted with that of adults is due to an inherent benignity of primary infection as contrasted with the malignity of reinfection, as some would have us believe.[34] Those who claim that primary infection is harmless and reinfection disastrous apparently limit their gaze to the examples of well resisted primary infections and to devastating reinfections. Certainly, they appear to ignore the many devastating primary infections so familiar in childhood, and they likewise gloss over the tremendous number of perfectly benign reinfections encountered in adults—the familiar, completely arrested apical scars of reinfection found so commonly at autopsy in individuals bearing older, calcified primary lesions. The truth, of course, is that the overwhelming majority of all tuberculous infections, whether primary or secondary, pursue a perfectly benign course to healing and permanent arrest, and there is no acceptable evidence whatever that reinfection is any more dangerous than primary infection, providing the dosage and the bodily vigor of the individual are the same in both instances. On the contrary, the entirety of the experimental and pathological evidence that we possess teaches us that, other things remaining the same, reinfection is decidedly less dangerous than primary infection.

In regard to the effects of hypersensitivity, in spite of the many assertions about its protective rôle, no one has yet brought forth proof of any sort that hypersensitivity is necessary for any of the protective effects of immunity. Our own numerous experimental studies of the matter, which I have reviewed in another place[44] and into which I cannot enter here, together with the subsequent similar investigations of Siegl,[48] Birkhaug,[6] Clawson,[24] Branch and Enders,[11] Higginbotham[26] and others, have demonstrated plainly that hypersensitivity is not necessary for any of the manifestations of immunity; and it has been known since the time of Koch that the hypersensitive state is responsible for exaggerated tissue destruction at sites where many bacilli are present. It does not at all follow, however, that the hypersensitivity produced by a primary infection "sets the stage" for devastating disease of reinfection, as some maintain.[34] I think that it is important in these matters to keep the known facts strictly where they belong. Reinfection is always instituted by only a relatively few bacilli, and a few bacilli provoke only a negligible immediate tissue damage even in the hypersensitive body. Serious damage from hypersensitivity becomes evident in reinfection only after a sufficient time has elapsed to permit the bacilli to multiply to large numbers; and it must

be remembered that after a similar lapse of time following the entry of the bacilli of even a primary infection, hypersensitivity will be just as highly developed. The amount of damage done by hypersensitivity, whether in primary or in reinfection, depends upon the degree to which the bacilli proliferate after reaching the tissues. If it is true that chronic phthisis occurs only in those who bear an earlier primary lesion, it is no less true that the acute, devastating, "childhood type" of progressive disease, with rapid local necrosis and caseation, and marked tendency to generalization occurs, in civilized races, only in those who have *not* had a previous primary infection.

The important and complex problem of the advantages and disadvantages conferred by a primary infection is bound up inextricably with the moot question whether adult tuberculosis results predominantly from exogenous or from endogenous reinfection. If phthisis is exogenous in origin, and rarely arises from activation of a primary lesion, as Opie[37] and many others believe, then it is obvious that a primary, arrested, immunizing infection could be no liability, and would be of great service in protecting against further infection from without, even though the protection were not always an effective one. If, on the other hand, adult tuberculosis is always the result of the lighting up of primary infections years after their establishment, as Fishberg[19] and others believe, then a primary infection would entail a large element of liability; though even in this case it would not necessarily be altogether disadvantageous, for if progressive tuberculosis can no longer be acquired from without, once a primary lesion has been established, then individuals with primary leisons would at least be protected against the danger of progressive infection acquired through contact.

The truth in all probability, lies in a midposition between these extreme views. There are probably many cases in which tuberculosis arises from the escape of bacilli from latent lesions of primary infection; many cases in which reinfection from without leads to progressive disease in individuals in whom the resistance conferred by a primary infection has become depressed by adverse conditions; and many cases in which the immunizing power of a permanently arrested primary lesion serves to protect the individual from further contact infection. There is now a great body of unassailable experimental and pathological evidence that infection does confer a very decided degree of resistance to reinfection, and it is without question true that the overwhelming majority of individuals who develop a primary lesion arrest the infection successfully and never develop progressive disease thereafter throughout their lives. That the resistance conferred by an arrested infection fluctuates under various influences, and is not effective in all cases in preventing the later development of progressive disease is, of course, perfectly obvious; and until we learn, if ever we shall, whether or not primary infection occurring in adult life would progress to a fatal termination more frequently than adults now develop fatal reinfection, statements purporting to define the virtues or the vices of primary infection can be no more than individual guesses.

In expressing my own belief that a primary infection does exert an immunizing effect which may be very valuable in many individual cases, I should like to stress the fact that there is no incompatability whatever between this view and the belief that all individuals should avoid spontaneous and uncontrolled infection as far as is reasonably practicable; for although the immunizing effect of a primary infection is a fact which can be demonstrated experimentally with the greatest of ease, in spontaneous human infection we can neither regulate the size nor the time of the immunizing dose, nor can we preserve all infected individuals from the external influences that act to rob them of their resistance while they still carry bacilli in their arrested lesions. Those who regard a primary infection as only a liability often seek to imply that all who recognize that infection does confer some resistance to reinfection are in favor of rushing every child into exposure to infection in order that the protective primary complex may be obtained as soon as possible. Of course this is in no sense the case. There must be few, if any, experienced students of tuberculosis today, whatever their beliefs about the primary complex, who favor any other course than that of protecting all persons from infection as far as is reasonably practicable.

Resistance in Old Age

I must devote a few remaining moments to the peculiarities of tuberculosis in the final period

of life. After sixty, the tuberculosis death rate tends to rise sharply, though in communities with an excessively high death rate in earlier adult life this tendency may be masked.

with less manifest symptoms than are usual in earlier years has led to the frequent statement that the disease is more benign at this period than in other periods of adult life. The high

TABLE V. FREQUENCY OF MILIARY TUBERCULOSIS IN THE AGED

Race	Age	Cases of Pulmonary Tuberculosis	Miliary Tuberculosis		Enlarged Caseous Nodes	
			No.	%	No.	%

Certainly, there is no question here of increased exposure to infection as a cause of the rise in mortality rate. On the contrary, the aged tend to withdraw from active contact with the world. A rising mortality rate in the face of diminished exposure to infection implies, in itself, the presence of factors that depress resistance, but is there, in addition, any clinical or pathological evidence that resistance is depressed?

In the aged, tuberculosis often tends to progress with strikingly little in the way of symptoms aside from the cough which, in itself, is often not severe. The disease is therefore frequently unsuspected, even when well advanced and with abundant bacilli in the sputum. A tuberculous grandparent with "chronic bronchitis" to which no attention had been paid, has often been found on investigation to have been the source of fatal tuberculous infection for children living in the same house. This peculiarity of the disease in old age makes it of great importance to investigate carefully the reason for a persistent but otherwise symptomless cough in the aged, particularly if they are in intimate contact with children.

I think that it is probable that the rather symptomless course is due in no small measure to the circumstance that not only do the aged engage in less physical exertion than do younger adults, but even in their normal state they are much more easily fatigued, and the contrast between the degree of fatigability in health and that after the onset of tuberculosis is much less noticeable than in younger age periods.

The fact that, clinically, tuberculosis may run a chronic course in the aged and may be borne

mortality rate hardly substantiates that view, and there is, in addition to the high mortality rate, some evidence from the pathological side that the resistance of the aged often tends to be less effective than in earlier adult life. Since the better the resistance the greater is the ability to localize the process, it is of interest that there are indications that the aged more often fail to immobilize their bacilli and to localize their lesions than do younger adults. Thus, Taubert,[50] Oppenheim and LeCoz[40] and Braun[12] have commented upon the frequency of fatal miliary tuberculosis in old age. Dr. R. H. Follis, Jr., and I have recently studied a series of consecutive autopsies on cases of progressive pulmonary tuberculosis from this standpoint. The results are presented in Table V, where it will be seen that the frequency of miliary tuberculosis in the old age group was much higher than that at other periods of adult life in the white race, approximating that in the natively less resistant adult negro. The series here presented is a small one, and does not pretend to fix a mathematical percentage incidence for general application. Together with the observations of the above mentioned investigators, however, it does serve to indicate plainly that miliary tuberculosis tends to be a much more frequent complication of pulmonary tuberculosis in old age than at any other period of adult life. Enlargement and caseation of regional lymph nodes, another evidence of deficient resistance, was likewise somewhat more frequent in our old age group, but decidedly less frequent than in the negro adult. Both Braun[12] and Taubert[50] comment on the occurrence of caseation of lymph nodes in old age—an event of great rarity in earlier adult life in the white.

More extended studies of the pathology of tuberculosis in advanced years of age is highly desirable. The available evidence, however, together with the rising death rate in the absence of increased exposure, serves to indicate that the aged have a lower degree of resistance than have the middle-aged. Precisely what the factors are that may be responsible for a decline in resistance in old age is not definitely known, but there are a number of circumstances which might well be operative in this direction. Old persons ordinarily remain indoors much more than younger adults; loss of teeth and of appetite not so infrequently result in varying degrees of malnutrition; diabetes, which appears to exert an unfavorable effect upon resistance to tuberculosis, becomes much more prevalent in old age. In the last U. S. mortality reports there were twenty-five deaths from diabetes per hundred thousand individuals in the forty-five to fifty-five year age period; eighty-seven deaths in the fifty-five to sixty-five year age period; and 177 in the sixty-five to seventy-five year age period. While factors such as these may contribute to the lowering of resistance in old age, they are certainly not the only ones concerned. There are reasons for believing that, in addition, specific though imperfectly understood bodily alterations associated with senility itself may act to impair the body's defence against infection.

In the first place, the lowering of resistance at this period of life is not peculiar to tuberculosis, but is evident in the case of other infections, of so widely different a character as dysentery, erysipelas and pneumonia (Table III). The susceptibility of old persons to pneumonia is familiar even to the layman.

It is probable that physical and mechanical bodily alterations attendant upon senility, such as enfeebled circulation and senile tissue alterations (*e.g.*, atrophy of the epidermis, senile emphysema), may be partly responsible for the more ready establishment of certain infections in certain tissues in old persons. In addition, and more important, a generalized lowered functional capacity of the organs and tissues characterizes senility, and there is no reason to doubt that the immunity mechanism shares in this general decline. In this connection it is important to point out that in very old age the isoagglutinin titre tends to decline to a level approximating in feebleness that present in infancy.[51] The parallelism between the isoagglutinin titre and the ability to form protective antibodies against bacteria and their products was pointed out above, and it is not surprising therefore that it has been established that persons of advanced age are decidely deficient in the ability to form antibodies against bacterial products in comparison with younger adults.

In this connection, it may also be recalled that there is much evidence that the lymphoid tissue is concerned in some way in resistance to infection in tuberculosis and in other bacterial diseases. The rôle of the lymphoid tissue in resistance cannot be discussed here, but I may recall as evidence of that rôle the fact that in animals raised from birth in a strictly sterile bacteria-free environment, the most striking deviation from the "normal" is an extraordinary inconspicuousness of the lymphoid tissue of the entire body;[21] and, on the other hand, the fact that marked proliferation of the lymphoid tissue in both the spleen (acute splenic tumor) and the regional lymph nodes occurs not only during infection, but also, as we have recently shown,[43] during antibody formation induced by even non-bacterial antigens. It is pertinent, therefore, that in old age there occurs a marked atrophy of the spleen and other lymphoid tissue, and that lymphoid proliferation during infections tends to be less conspicuous than at younger age periods.

The peculiarities of susceptibility and resistance at the various age periods, and the manner in which external factors act to alter resistance, constitute perhaps the most important problems in tuberculosis today, not only from a theoretical but, indeed, from a highly practical standpoint; and they deserve the most serious and intensive investigation. In this review of the general outlines of the problem, I have sought chiefly to stress the narrow limits of our present information, rather than to attempt to provide a series of comfortable, theoretical explanations for these complex and incompletely understood phenomena.

THE ROENTGENOGRAPHY OF PULMONARY TUBERCULOSIS*

With a New Method for Group Surveys

HOLLIS E. POTTER, M.D.

Chicago, Illinois

AS WE gather here today to discuss certain x-ray aspects of pulmonary tuberculosis let us pause for a moment in memory of our mutual and beloved friend, Dr. Russell D. Carman, in whose honor this hour has been set aside. I presume I knew Russell Carman rather intimately before most of you. I knew him best in the years before he came to Minnesota and in those years I can assure you he was quite as interested in the x-ray diagnosis of pulmonary disease as he later became in gastro-intestinal lesions. I may say quite truly that I gained quite a bit of inspiration from his early work on pleurisy and tuberculosis of the lungs and if he were here today I am sure he would heartily approve of spending this hour on the subject of tuberculosis.

*The Russell D. Carman Memorial Lecture presented before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

I am sure he would agree with me when I say with no reservations that in all the special fields of medicine where our poor attempts at x-ray diagnosis have gained foothold there is no disease in which we are able to render a more decisive and more valuable service than in the handling of adult pulmonary tuberculosis. Russell Carman and I were active in an era before 1910 during which the average clinician hooted the idea that significant tuberculous lesions could be fairly demonstrated by x-rays in a case where the more classical symptoms and signs were absent. This was the day of the so-called tuberculosis specialist whose very livelihood depended on a public recognition of his superhuman skill in physical diagnosis. He could not afford to recognize any method which would tend to amplify, replace, or debase his special attainments. Fortunately for the human race the specialists of this character are now either dead or very few in number. The most dependable tuberculosis workers of today are free to admit that most early pulmonary tuberculosis should be seen and not heard.

In fact it was not until some of our foremost clinical workers in the tuberculosis field incorporated the x-ray into their own routine practice, checked it carefully against other tangible factors in the diagnosis and followed up their results in an open minded manner that the x-ray method became widely accepted, so that it is now considered the one most important factor in the diagnosis. In this connection, I cannot too strongly express my gratitude for the work done and reported by Dr. Lawrason Brown and his associates at Saranac. It is true that the technic of the old days produced results that were far less convincing than are the brilliant sharp films of today, but the widespread acceptance of the x-ray method has been brought about quite as much by the study and educational work of clinicians and roentgenologists as by the outstanding technical improvements.

As we admit, therefore, that x-rays are rather widely used in general practice and most lavishly used in hospitals and sanatoria, what valuable message might I succeed in bringing you today? What great lesson has the medical world yet to learn about x-rays in relation to tuberculosis? My answer is that too few of the medical men yet understand the low percentage of early cases that are really diagnosed in general practice. One authority states that in a hundred consecutive chest cases where the diagnosis of tuberculosis is correct, less than 5 per cent are discovered in an early stage, less than 15 per cent are discovered at a moderately advanced stage and more than three-fourths are far advanced. Such a startling percentage of advanced cases at first discovery is most often to be explained by the lack of symptoms on the part of the patient sufficient to make him call on his doctor. The balance are either unrecognized by his doctor or sympathetically minimized until the pathologic process gives outspoken signs and symptoms. The insidious onset of so many of these cases demands that if 25 to 40 per cent are discovered early it must be done by some widespread survey in which the doctor goes to the people rather than waiting for the people to come to the doctor. Somewhere our system is wrong and medical practice and medical ethics must be modified to meet the facts. My message then is obviously to encourage some proper system of group surveys and to insist on a more widespread use of x-rays in private work. Personally, I cannot anticipate the discovery of an outstanding majority of these cases in a minimal stage because a real percentage of them are serious from the start and could never be classified as minimal or benign.

I will skip the old controversial question as to whether tuberculosis can be shown earlier by x-rays or by some other method except to express a firm belief that by x-rays the parenchymal lesions can be shown, if not identified, in more than 95 per cent of the cases. Roentgenologists are often criticized for venturing any opinion as to the identity of tuberculosis as shown on x-ray films and severely censured when trying to estimate its probable activity. Regarding the identity there may often be a reasonable doubt. When the lesions are simple and possess characters more or less typical for tuberculosis, I describe them as "tuberculoid" in type and leave it for the clinician and the future to determine whether actually "tuberculous." Regarding questions of activity, chronicity and healing I would maintain that the competent roentgenologist can contribute most valuable information on these points. Frequently, when the state of activity is indeterminate from the study of a single set of films the true condition may be learned from films made after a short period of time. He who can see no difference in character between a frankly active and a near-healed

lesion is not in a position to criticize another who in the light of considerable experience ventures a guarded opinion on one of the intermediate stages.

All things considered, I would mention about ten diagnostic aspects of work in adult pulmonary tuberculosis in which x-rays may be found most helpful.

1. In the negative findings, or determining the absence of a significant lesion.
2. In determining the presence and extent of involvement.
3. In recognizing the probable identity of the lesions in a majority of the cases.
4. In the differential diagnosis.
5. In recognizing the general pathologic form of the disease as an aid in its classification.
6. In recognizing evidences of activity, chronicity, and healing.
7. In the recognition of cavities.
8. As an aid in prognosis.
9. As a guide in determining and following up the surgical procedures.
10. In recognizing evidences of unfavorable advance, dissemination or complications.

Let us, now for the moment, turn back the chest wall and observe some of the basic facts regarding tuberculosis. We find that pathologically there are four main types of the disease, each having its own prognostic implications, but that in many advanced cases the lesions of various types are found together in the same person. At the onset the pathologic type is determined as a resultant between two opposing forces. On the one hand the invading force is measured by the number and virulence of the tubercle bacilli. Opposed to this is the resistance of the invaded host. We find that the architectural pattern of the lesions tends to conform to the mechanics of whatever portion of the lung is invaded, whether a whole lobe, a sub-lobar division, a single lobule or a single acinus.

In the simple or exudative type a minor focus of tuberculosis is completely surrounded and overshadowed by a diffuse homogeneous exudate, the so-called peri-focal reaction or collateral inflammation. On x-ray films it gives a diffuse homogeneous shadow like pneumonia. Only at a later period may further films disclose its tuberculous character by showing a small mottled and nodular residue after resorption of the reactive exudate.

The exudative-productive type is also relatively benign. Its scattered lesions for a time show a melted homogeneous appearance at periphery as from peri-focal exudate, but later, upon clearing, a more resistant nodular central zone appears which remains for some time before complete healing. These productive or proliferative features distinguish it from the exudative type. Upon complete healing it leaves but slight scar either linear or nodular. In these simple forms the intensity of the process does not reach the stage of real necrosis, and cavity formation.

Much more serious is the third type often called the caseous-pneumonic type. In this type more or less massive necrosis does occur and if the patient survives the first onslaught, caseation, liquefaction, evacuation and cavitation follow in due order. In fact, necrosis is its outstanding feature whether this be a necrosis of a whole lobe as in the form called acute pneumonic phthisis or a necrosis involving individual scattered lobules as in the form called acute bronchopneumonic phthisis. The caseation and cavity formation in these cases account for the condition which results in the prolonged or lifetime disability seen in those sub-types known as chronic ulcerative and chronic fibro-ulcerative tuberculosis. These cavity cases fill our clinics and sanatoria. These call for our mechanical and surgical handling.

In the first stages of caseous-pneumonic tuberculosis the density conditions are uniform throughout the involved area so that x-ray appearances may quite simulate the simple exudative type. In the course of a short time, however, when caseation, liquefaction, and evacuation have taken place, a central clear zone indicates the presence and general features of cavity. Gradually the peri-focal exudate may be resorbed and the external portion of the single or multiple cavities become well defined. Delayed absorption and atelectasis are not uncommon in the portions distal to the cavity.

The fourth general type is known as chronic proliferative tuberculosis. It is the result of a long series of super-infecting doses over a long period, seldom accompanied by any show of peri-focal exudate and mainly visible in the form of discrete linear or nodular scars. Starting often in the apex, the lowermost lesions may show diffuse borders testifying to their more recent activity.

No one who gets this bird's-eye view of the

pathology can fail to appreciate the seriousness of the caseous-pneumonic form and no one can fail to recognize the outstanding importance of the necrosis and cavitation sequence. The cavity is perhaps the key lesion upon which prognosis and therapy so largely depend. The early cavity is ragged at margin, irregular in form and tends to lie in the center of a mass shadow of more or less homogeneous density. The early detection of cavity is difficult but important because collapse therapy may then be instituted before adhesions are formed and before a resistant cavity wall is developed. Cavities larger than a cherry seldom heal spontaneously, since they lie in an area of negative pressure, and a valve-trap mechanism in the bronchus may even result in their distention and enlargement. It seems futile to attempt a classification of adult pulmonary tuberculosis without recognizing the cavity as the key lesion.

X-ray interpretation of tuberculous chest lesions is best conducted by one quite familiar with their various pathologic forms in the many and various stages of activity, chronicity and healing, but his ability will depend most particularly upon a vast experience in observing the x-ray findings alongside the clinical state of patients throughout that entire period of time required for their recovery or their death. This experience is greatly amplified by post-mortems on the fatal cases he has studied during life, but in the post-mortem he must not be confused by the pronounced terminal changes which were no part of the picture until the end. He learns to recognize consciously or unconsciously certain shadow structure criteria which are fairly characteristic though not pathognomonic of the disease. He observes the number, size and distribution of the lesions; their outline form and density; the character of their margin; their internal pattern of structure; and their relationship to other pulmonary structures. Certain combinations of these topographic, density and outline form characters are so often repeated in his experience that they come to have important meaning in respect to the kind as well as the degree of pathologic activity.

Topographically the novice who recognizes the single rule that primary adult reinfections are to be found above the hilum is much more often right than wrong. Our older conception that these changes were oftenest in the apex has been broadened to include the subclavicular region and particularly the shoulder periphery. Cavities which represent the climax of the invading process are far up, far back, and far out in more than 95 per cent of cases. Primary reinfections, whether exogenous or endogenous, are rare in the base of the white man's chest and probably less rare in the colored.

Dunham taught us to consider certain of these simple upper lung field lesions in terms of a fan whose handle lies at the hilum and which then spreads out toward the upper periphery as the invaded lobules enlarge. In many others, however, one fails to get the complete fan form but simply sees a large number of more or less discrete nodular deposits, commonly called apical or sub-clavicular infiltrations. In an especially allergic individual the field of involvement may for a time give the impression of a simple pneumonia of lobular or sub-lobar size because of the diffuse over-shadow cast by the exudate.

In a more severe case the involved area is homogeneous and denser until after evacuation of a liquefied area at the center, when our first sign of cavity is noted. Areas peripheral to the cavity may be largely resorbed or may remain in shadow. When patches of clearing occur on the side toward the hilum they must not be misinterpreted as cavities although they present somewhat similar appearance on a single film.

In the secondary reinfections and spread of the disease, new fan-like areas may be seen on the opposite side in apex, mid-lung field or base which often look quite similar to the first upper lesion. In the more advanced caseous-pneumonic cases with multiple cavities and lesions of every age intermingled or superimposed, the picture may become too complex for detailed analysis of each individual lesion.

The roentgenologist is justified in making inference of favorable resolution and healing when exudates become absorbed and the residual nodes shrink down over a period of time to a small nodular or linear form. Larger nodes that persist are eyed with suspicion because of the experience that caseous areas do not always evacuate but are sometimes encapsulated, and may undergo a breakdown at any favorable time. By the same token lesions which show discrete linear or small nodular characters over a longer time may be considered as "arrested," or, finally, as "apparently healed."

From the foregoing statements one can readily see that information obtained from films made at first discovery of tuberculosis is greatly amplified by any subsequent films which reveal a forward or backward trend in the disease. Made from time to time at intervals depending on the activity of the case they aid greatly in prognosis and in a way provide a graphic pathologic history of the disease.

My time is rather too short to point out the weak aspects of the x-ray in detecting tuberculosis but I wish to focus your attention on one peculiar paradoxical situation in which the tubercle bacilli are microscopically apparent in the sputum yet the x-rays show no pulmonary changes. I mean real radiographs and plenty of them on one day. Whether you are a conservative or a liberal you have to look this paradox in the face. It has been explained by pathologists in the last few years by the fact that occasionally a caseous lymph gland ulcerates directly into a bronchus and gives the positive sputum findings. The x-ray examination gives negative findings because on that day there was no pulmonary lesion, the bacilli coming from the gland.

Radiographs then made in a month may show a positive lesion of typical character at some point in the lung. We can only explain this as a dissemination from the gland through the bronchi into the lung similar to the dissemination from a cavity, and we may be thankful that such cases are so rare as to change our accuracy less than 1 per cent.

A very common mistake in the past has been to interpret incorrectly the ordinary prominent linear structures proceeding downward from the hilum as tuberculosis when the upper lung fields were clear. The term "peribronchial tuberculosis" was coined to designate this type of the disease and it was not until the pathologist declared there was no such type and clinicians found it did not progress or change with the years that the term was discarded and the finding discounted.

One outstanding weakness in the x-ray system is the absence of information we can get regarding the chain of lymph glands which lie about the trachea and bronchi, and so often harbor sizable areas of highly infected caseous material. While these encapsulated foci seldom break down and directly infect the adjacent lung areas, they nevertheless act as reservoirs of infection which may be transferred elsewhere by the blood stream. It is probably only fair, when we emphasize so strongly the value of x-rays in detecting tiny lesions in the parenchymal portions of the lung, that we as freely admit our great limitations in detecting the inside structure and true nature of these all-important tracheo-bronchial lymph nodes.

In the next few moments, I wish to present for your consideration and criticism a series of experiments carried out in the laboratories of the General Electric X-ray Company at Chicago. I wish to emphasize that I did not personally conduct these experiments but acted in an advisory capacity. It is through the courtesy of their president that I am now able to make this first public mention of the work. When entirely completed an account of this work will undoubtedly find its way into the proper technical and medical prints.

The experiments consist of new attempts to photograph the fluoroscopic image directly from the screen. Almost since the discovery of x-rays men in various countries have attempted this with various poor degrees of success. Of late years they have tried to make moving pictures of the heart, lungs and stomach for teaching purposes or even for diagnosis. Our efforts were limited to obtaining the finest possible single miniatures of the chest hoping they would still be large enough and of such excellent quality that they could be used in place of the large, bulky and more expensive films now used. We think we have overcome many of the past difficulties in a very fair way.

Heretofore, the first great obstacle in obtaining brilliant and valuable miniatures from the fluorescent screen has been a limitation in speed. The capacity of generators and the capacity of tubes has been enormously increased but not enough to compensate for the limited brilliancy of the fluorescent screen, the speed of available lenses and the speed of such available photographic film as might be considered adaptable.

The first step was to obtain the most rapid screen possible. The ordinary green fluorescent screen was laid aside and a brilliant blue-violet fluorazure screen made of particularly large crystals of calcium fluoride was substituted. Without the usual blue covering material intended to reduce lag, this screen as developed by a competent manufacturer increased the speed seven-fold

when used together with a film especially sensitive to blue and violet.

Using this screen, we then tested out all the very high speed films in the world's market. The tests were made with an f 1.5 lens which would cover one frame of a 35 mm. movie film. A rotating anode tube receiving 400 ma. at proper voltage was found to deliver through the average chest at four feet sufficient x-rays to fully expose certain of the films in a tenth of a second. It may sound peculiar, but the film which showed the greatest speed and best working qualities was no other than our common everyday x-ray film. Many of us do not know that this film is critically sensitive to the particular color values emitted from this fluorazure screen.

But the diminutive 35 mm. size was obviously too small for direct diagnostic reading and all attempts to enlarge these films to a three or four inch square size brought out so much obnoxious grain that they were considered of no practical value.

We next concentrated on the lens problem, trying to find a lens of sufficient speed that would cover a larger film without subsequent enlargement. Tests on an f 2.0 lens that would cover a two-inch square film showed that a chest exposure could be obtained in about two-tenths of a second but the films look a little starved and were too small for large film substitutes. Their enlargements, however, gave much less grain prominence.

Using the same power and distance factors, an f 3.5 lens which would cover a four-by-five film was then used. This gave rather good miniatures in half a second. They seemed quite large enough for direct reading and showed no appreciable grain. The films, however, often showed movement in the lower pulmonary structures just as half-second films do in the larger sizes and it was considered necessary to consult lens manufacturers about a lens of f 1.5 speed that would cover a three or four-inch square film.

At first, we were told that no lens of this character had ever been constructed but possibly could be. Shortly, it was learned that one lens of this speed which would cover a three and a quarter-inch square film had been constructed for rapid night photography from aeroplanes and we were extremely fortunate in obtaining a short time loan of this lens to continue the experiments. Naturally, it was a very large lens, having a diameter of about six inches and weighing no less than twenty-six pounds. Now, using the same rapid screen, a rotating anode tube and the same power and distance factors, a series of chest miniatures was then obtained which seem to answer all requirements. They are brilliant, fully exposed in a tenth of a second or less and quite free from grain. We are pleased to submit these films for your inspecition and criticism. Although but three and a fourth inches square they show, with faithfulness, every detail present in standard sized films of the same chests.

A lens of this large size was then immediately ordered and has been recently delivered. It differs from the borrowed lens in that it has a higher light gathering power and is designed to focus the blue-violet light which altogether doubles its efficiency. The next experiment will be to place the equipment in a local tuberculosis sanitarium where a large series of films will be made from pathologic chests to be compared for readability with the standard sized films at hand. These may then be submitted to a group of experts for evaluation.

Should miniature films of this size and quality prove to be an adequate and practical substitute for our present standard sized films in the case-finding program of a tuberculosis survey you will quite agree that the filing and storage problem will be greatly simplified. The material expense for a single film is reduced to about five cents. This means that in a thousand cases the film cost alone will be lowered from about six hundred dollars to about fifty dollars.

THE FOOT AND ANKLE*

Their Discomforts, Deformities and Disabilities

PHILIP LEWIN, M.D.
Chicago, Illinois

I HAVE chosen a subject which is large both anatomically and geographically. I wish I could cover the subject from every practical point of view, including the orthopedic, industrial, surgical, roentgenologic, dermatologic, genito-urinary, obstetric, gynecologic, neurologic, sociologic, economic and arthritic aspects, but that is obviously impossible. I have tried, however, to keep uppermost in my thoughts the function of the foot and ankle, which means their physiologic activity, their usefulness and comfort; in short, their "performance."

It is important to be able to arrive at a fair estimate of percentage of partial or total disability in order that both the patient and the employer be treated fairly.

A man who has had a fracture of the leg, thigh or foot, after weeks of treatment, may appear to have an excellent cosmetic and roentgenographic result, but he says his foot hurts and he can't walk; he doesn't walk and he won't work. I am interested in what can be done to give him a good functional result.

The relation of feet and their defects to other complaints such as backache, sciatic pain, knee pain and hip pain, is sometimes very close and occasionally brilliant results follow correction of foot imbalance. While I feel that the foot condition should not be underestimated, I do not lay too much stress upon this part of the examination, because the local complaint, such as backache and sciatic pain, must be thoroughly investigated, independently.

It would be impractical to consider foot lesions apart from the leg because the functions of the two members are closely associated. Every organ or tissue may react upon the general health, usually by the infectious, glandular or metabolic routes, but the feet, in addition, may react mechanically.

Foot abnormalities may be indicators of disturbances of the general health. Just as the eye specialist may, from an eye examination, suspect a serious lesion of the kidneys, so the orthopedic surgeon may find evidence of disturbances of the general health, which, if thoroughly investigated, may reveal important facts. A doctor's wife consulted me because of a simple metatarsalgia. She had a spastic condition with disturbed skin sensation and some ataxia. I advised a neurological examination, which revealed evidence of a tumor of the spinal cord, which was proved by operation.

The foot cannot be treated as an isolated member, but must be considered a part of the human organism. This is especially true of mechanical disturbances of the feet and legs which are aggravated by constitutional abnormalities such as infections in the teeth, throat, sinuses, ears, glands, chest, stomach and intestines, genito-urinary tract, and disturbances of the circulatory apparatus.

It is possible to judge some of the mental and physical characteristics of an individual by his gait.

An employer when engaging an individual will observe if that person has a springy gait or if he has a slouchy, dull, rigid gait. If one observes a large number of people walk into a room that has a runner of carpet, he will see some trip, proving that many people do not lift but drag their feet.

Shoe fitting is an art that requires years of experience, a proper determination of the type of shoe and a complete stock in order to fit the foot properly. Much progress has been made, through coöperation of shoe manufacturers with the orthopedic profession, in the manufacture of shoes for children and men, but women's shoes are still far from perfect. There is no one brand or type of shoe that is appropriate for every type of foot. Important advances were made in the solution of the static foot problem by the work of The American Posture League which divided feet into straight, inflare and outflare varieties. High heels tend to produce sway-back.

In many of our United States a license is required of every blacksmith who shoes horses, but I want you to show me one state in which

*Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1938.

the human shoe fitter is required to have any special qualifications.

The chief foot defects are: Congenital defects, deformities and disabilities; acquired deformities and disabilities; diseases of bones, joints, muscles and nerves; traumatic conditions of bones, joints, muscles and nerves; paralytic conditions; circulatory disturbances, and tumors.

Congenital defects include absence of toes, constricting bands, supernumerary toes, syndactylism, congenital hypertrophy, congenital overgrowth of leg and foot, overlapping toes, and bipartite sesamoid bones.

Congenital deformities include various types of talipes.

Acquired deformities may be due to tuberculosis, syphilis, infantile paralysis, spastic paralysis, infections, flat-foot, metatarsal depression, bursitis, hallux valgus and exostoses.

The important traumatic conditions are fracture, dislocation, epiphyseal separation and epiphysitis. Warts, papillomas, corns of both the hard and the soft varieties and most circulatory disturbances are acquired.

Diseases of the foot are chiefly tuberculosis, syphilis, osteomyelitis, epiphysitis or osteochondritis such as Köhler's tarsal scaphoiditis. Freiberg's infraction of the metatarsal head, apophysitis of the os calcis, arthritis due to gonococcus, staphylococcus, streptococcus, metabolic and traumatic causes are common in the foot.

Tumors of the foot are chiefly lipomas, fibromas, osteomas, angiomas, sarcomas, melanomas, and melanoblastomas.

In 1781, Peter Camper, Professor of Medicine in Amsterdam, published a book entitled "A Dissertation on the Best Form of Shoes." According to Bick, it included a detailed anatomic study of the foot and its arches, and illustrated many of the distortions caused by pointed shoe toes, tight shoes, and other defects of the last. James Lowie, an Edinburgh shoemaker, quoted from an English translation as follows: "Shoes which are not adapted to the foot of each individual are defective; and a shoemaker who would excel in his art ought to have an exact knowledge of the diversity of form, more especially if he wishes to prevent corns upon the joints, and between the toes, inflammation of the roots of the nails, especially of the great toes, and painful callosities. . . . He will prevent all these annoyances by giving a proper form to his shoes." Camper, who was a scientist, an anthropologist and an anatomist, virtually introduced the subject of static foot deformity. Following him, LaForest, a Frenchman, wrote a book, and from that period on, increasing studies on foot mechanics appeared.

The importance of foot disabilities other than those causing obvious gross deformity such as club-foot, was not appreciated until 1781, when Camper wrote his memorable Dissertation on the Best Form of Shoes.

The study of the mechanics of human gait offers the only physiological basis for an intelligent approach to the treatment of static foot disorders.

In 1836 the Weber brothers published a volume on the mechanics of locomotion, containing the first serious scientific study of human gait. They stressed the importance of the pendulum action of the lower extremities during locomotion, and described in great anatomic detail the muscular and articular structures involved.

Janssen suggested the study of gait by means of serial pictures, but the first successful application of the method was that of Carlot, in Paris. He made graphic records of the human gait by means of shoes built with rubber soles in which were placed air compression chambers for the heel and forefoot. Carlot published his observations in 1872. Three years later Marey published another volume on locomotion in man and animals in which Carlot's air chambers were also used. Bradford was among the first of the American orthopedic surgeons to study the problem. Muybridge was said to have been the first to use an electric photographic method for recording gait (1925). This has been modified and improved from time to time. The most recent advance in the study of gait has been made by R. Plato Schwartz and his co-workers whose electrobasographic methods of recording gait, described in 1933, has offered refinements in study not previously possible.

Along with the development of methods for recording gait, the study of foot function from the anatomico-physiological viewpoint has proceeded with parallel progress. Duchenne, during his classic investigations on muscle function, was the first to note a specific relationship between muscular imbalance in the leg, and the everted foot. He felt that the most important

factor in locomotion was well coördinated muscle control of the limb and its individual segments. Delpech, the master of French orthopedics, made a similar observation, so that the myogenic etiology of static foot deformity was early impressed upon French students. Toward the end of the nineteenth century, Royal Whitman distinguished between true flat-foot, and a pseudo flat-foot, in which the foot and leg become everted, painful, and, in advanced cases, more or less rigid.

The concept of the "weak foot," flaccid in its early stages and rigid in advanced cases, has almost entirely superseded the older concept of flat-foot.

Against the myogenic theory of static foot deformity has been brought the hypothesis of the stretched plantar or calcaneo-navicular ligaments. According to this hypothesis, the pain and disability of foot dysfunction is due to a gradual elongation of the tarsal ligaments, consequent upon faulty habits in walking and standing, or the use of improper shoes. Keith, however, emphasized what Duchenne had suggested, the fact that the interosseous ligaments are but secondary supports in weight bearing extremities, and are only called into play when the musculature of the part becomes ineffective. He referred to them as the "fatigue structures." As such, he maintained that their being stretched, or elongated by persistent passive strain, must of course presuppose inadequacy of the muscles concerned. The osseous theory of this deformity, which gave to it the popular name of "fallen arches," was based on the assumption, held especially in England, that the bony longitudinal arch of the foot was a true arch with the navicular or head of the astragalus as its keystone. This theory was refuted by the British orthopedists, Golding Bird, Adams, and Walsham, but it is constantly reiterated in the literature, especially in connection with operative methods of treatment. The literature of the nineteenth century contained a tremendous bibliography of books, monographs, theses and papers on the subject of foot deformity, a good proportion of which dealt with flat-foot. However, the work of Whitman and the advent of roentgenography invalidated many of the purely speculative concepts. In 1885, Shaffer described a painful static foot deformity of no specified etiology characterized by a high longitudinal arch, extended proximal phalanges, almost a mild pes cavus, the so-called hollow foot. Although its etiology has never been determined, except for the hypothesis of short shoe-wear, Shaffer thought its pathogenesis to be a contracted tendo achillis. In 1876, T. G. Morton introduced into the literature the term metatarsalgia, a type of foot disability in which severe pain occurred in the region of the metatarsal arch. Morton believed the symptoms to be neuralgic in character, and described pain radiating into one or more toes due to pressure on the digital nerves as they passed between the heads of the metatarsal bones. Goldthwait, in 1894, and Robert Jones, in 1897, demonstrated that this was primarily due to a prolapse of the metatarsal arch. Another lesion giving similar symptoms had previously been described by Breithaupt (1885). This lesion, known variously as marchfoot or *pied force,* was fairly common among soldiers following long marches, and was treated as a strain or sprain until roentgenography disclosed its true pathologic change to be an infraction of a metatarsal bone, in which the fracture is not perceptible until some time after the appearance of symptoms. It resembles to some extent Kümmel's disease in the vertebræ.

To Hugh Owen Thomas, the great Liverpool surgeon, all static deformities of the foot were a problem of joints and ligaments rather than muscles. In the treatment of flat-foot, he introduced the raised and forwardly extended inner border of the heel of the shoe. During the middle of the last century the use of "arches" came into vogue. These "arches" or foot plates act as braces for the bones and ligaments of the longitudinal arch "which has broken down," or, as in the Whitman brace, serves to actively invert the foot, thereby bringing it into normal relationship and relieving the supporting musculo-tendon mechanism of undue strain. There has been a constant controversy between those who advocate rigid plates, and those who advocate non-rigid supports. The spring-arch first appeared rather generally in the literature during the nineties. Any reasonable support in an adult, adjusted with a proper appreciation of the mechanics of the deformity, can become suitable for the particular case. Foot supports have been made from steel, duraluminum and other metals, celluloid, leather, cork, wood and rubber. Thomas said: "It isn't the apparatus, it is the principle underlying its application that is important."

In children, adolescents and young adults, the tendency has been away from rigid supports, and

in favor of exercises aimed at strengthening the involved muscles. Although foot plates are frequently used for temporary assistance, in younger patients many orthopedists feel that the raising of the inner border of the sole is sufficient to invert the calcaneus during the period of exercise or other physical therapy. These exercises are planned to strengthen specifically the anterior and posterior tibial muscles, and in some instances the intrinsic muscles of the foot. It is felt with increasing confidence that, at least in younger patients, such treatment affords an effective cure. Many surgeons vary their methods with the individual patient. Plates, manipulations, and exercises assisted frequently by physical therapy are used interchangeably. The painful foot represents a large proportion of private practice in probably every orthopedist's office. By the time these patients reach the orthopedist, the disability requires far more attention than the simple application of a rigid support.

The rigid or spastic flat-foot presents a difficult problem. To Royal Whitman is due credit for valuable study of this deformity, and the most effective methods of treatment. In such cases, correction by the simple use of foot plates or braces is impossible. Most cases, however can be improved by manipulation under anesthesia, followed by a plaster-of-Paris boot to maintain the over-corrected (inverted) position. After removal of the plaster the foot is stretched daily for a prolonged period of time, and the foot braces are worn as described by Whitman. For the very resistant cases, in which recurrence follows even the most painstaking treatment, operation becomes necessary.

Surgery of the Foot

Bone operations designed to correct deformities of the foot are, because of the highly specialized anatomy of the part, peculiar to themselves and represent a course of development in many instances quite distinct from the general rule of operations applied elsewhere upon the skeleton. Bick recalls that Fabricius Hildanus removed a fractured talus in 1608 to overcome the resulting disability. In 1741, Broglie repeated the procedure in a similar case of long standing with the intent of correcting the deformity. The operation was again performed by Marrigue in 1782, and Desault in 1788. Broca, in 1852, and Lund, in 1872, advocated the removal of the astragalus for local destructive disease, and in 1857 Cock suggested the extirpation of the astragalus, scaphoid, cuneiform and cuboid for the same indication. In 1857, Solly removed the cuboid in an attempt to correct the deformity of club-foot. In 1878, Albert, a Viennese orthopedic surgeon, conceived the idea of employing a stabilizing operation for the relief of paralytic deformities of the foot. In order to accomplish this he adapted his method of arthrodesis to the bones of the tarsus, denuded the articular surfaces of their cartilages, and allowed fusion to occur during a period of immobilization. In the same year, and later in 1888, Golding Bird performed a similar operation, but applied it to severe flat-foot deformity. He removed the navicular, and in some cases also the head of the talus. The earlier case was probably the first occasion in which surgery was used for the correction of flat-foot. In 1884, Ogston performed a talo-navicular arthrodesis, also for flat-foot, by resect-the head of the astragalus, and denuding the articular surface of the navicular. He continued this procedure, but later, when necessary, he secured the two bones by an inserted ivory peg. He then sutured the surrounding soft parts, and immobilized the foot. Shortly after this, Stokes advised merely the removal of a wedge from the head and neck of the astragalus. In advanced cases of valgus deformity. Trendelenburg advocated fracturing the tibia and fibula above the ankle joint, permitting union with the foot adducted.

In 1901, Royal Whitman performed the first astragalectomy on a paralytic foot in a case of calcaneus deformity. In this operation he not only extirpated the astragalus, but, by displacing the foot backwards, gained the advantage of a direct line of support from the tibia through the mid-tarsus. It secures excellent stabilization without obliterating motion at any of the tarsal joints; and can be performed in children at any age. In 1908, Jones described a fusion operation for calcaneo-cavus, and later Dunn devised a similar procedure for several types of paralytic foot deformity. Goldthwait, also in 1908, tried the effect of fusing the ankle joint in cases of complete paralysis of the foot. In 1911, Lorthoir reported eight cases in which the astragalus was removed, denuded of cartilage on all sides, and replaced. The intent here was to effect a multiple arthrodesis. In 1913, G. G. Davis, of Philadelphia, described a type of fusion opera-

tion, or arthrodesis, which, unlike those of his contemporaries, involved only the subastragalar joint. Whitman's operation, and the arthrodesing types of operation, have formed the basis for many subsequent modifications since developed by Hoke of Atlanta, Ryerson of Chicago, and others. Hoke's arthrodesis is one of the most important contributions to this subject. According to his technic, the head of the talus is removed, and reshaped to accommodate itself to the deformity. It may be replaced or if advisable left out altogether. The articular surface of the navicular is denuded to allow for subsequent talo-navicular fusion. Secondly, the articular surfaces of the cuboid-calcaneal joint are fused, and lastly the subtalar joint is arthrodesed. Ryerson conceived the idea of constructing a bone ledge at the anterior border of the talus to check dorsiflexion in cases of paralytic pes calcaneus. In addition to these basic procedures, Jones, Garre and Kuttner, Perthes, Schwarz, David, Gill, Putti, Ombredanne, Steindler, Campbel, Zadek, Lambrinudi, Mayer and others have advised numerous modifications and additions to the surgical correction of paralytic or severe static deformities of the foot. Among these operations are Jones' transverse osteotomy of the tarsus, Zadek's wedge osteotomy, Steindler's stripping of the plantar fascia for the correction of cavus, and Campbell's bone block for equinus. This latter has recently been simplified by Wagner. Mayer of New York formerly corrected such deformity entirely by tendon transplantation, but has recently added to his original procedure a modification of Hoke's operation. Gallie, Whitman, and others have likewise devised methods of relieving such deformities by means of muscle-tendon operations, but in general these have not met with the same acceptance as have procedures practiced upon the bones and articulations. In 1921, Soule proposed driving a bone pin through the navicular into the talus in cases of marked valgus deformity. Gleich sawed the calcaneus in an oblique direction and shifted the posterior fragment forward. The non-operative treatment of club-foot is not far different today from what it was during the Hippocratic era. As early as the sixteenth century, corrective braces were used, and these have been modified ever since. Paré, Glisson, Hunter, Venel, and Scarpa have all devised apparatus for this purpose. Theories of etiology have been numerous and variations of therapeutic measures have, to some degree, depended on the contemporary theory in vogue. The possibility of intrauterine mechanical restraint was held by Hippocrates, Scarpa, and Paré. Bessel-Hagen, in 1899, restudied the subject in the human fetus, and came to the same conclusion. Arthur Keith believes that the phylogenetic evolution of the human foot adequately explains the condition of club-foot if one assumes a developmental rest of the fetal foot at an anthropoid stage.

Hugh Owen Thomas advocated the immediate forcible correction of the deformity, to be followed by a retention splint devised to maintain an over-corrected position. For this purpose, he constructed an osteoclast of special design, the "Thomas Wrench." Grattan, of Cork; Bradford, of Boston; and Lorenz, of Vienna, adopted the method in their extensive practices, and also designed similar, though modified, osteoclasts. Lorenz later made use of a padded pyramid over the apex of which he "broke" the deformity. According to Brockman, the French orthopedic surgeon, Guerin, in 1836, was the first to use a plaster bandage to splint the corrected club-foot. However, it was not until twenty years later that plaster-of-Paris was introduced and became popular in the treatment of these cases. A great step forward was made after overcoming considerable resistance, when the advisability of treatment at the earliest possible moment was realized. Until the end of the nineteenth century, treatment was deliberately delayed until early childhood. The practice of correction in early infancy has done more than anything else to solve the problem of club-foot. Zadek and Barnett, who studied a large series of end-results, found that the subcutaneous section of the tendo achillis and posterior capsule of the ankle joint was of additional advantage in certain cases. Failure to correct equinus is a cause of recurrences.

A notable advance was the introduction of operative methods for correction of cases seen in late stages with bone deformity. The use of achillo-tenotomy, as introduced by Stromeyer and others, will be discussed later. Many operations aimed at the correction of the malformation of the tarsus were popular during the nineteenth century. Augustoni and Morestin attempt to improve the position of the foot by removing the astragalus; Championniere removed several bones of the tarsus in addition to the astragalus; Gibney excised only the head

of the astragalus, or in other instances the proximal end of the fifth metatarsal; Muller, Robert Jones, and many others practiced the removal of wedges, cut from almost every conceivable angle, to produce purely mechanical or cosmetic correction of the deformity. In addition, the intra-articular surfaces of almost every tarsal joint, and combination of joints, have been resected and arthrodesed.

In 1892, Bradford wrote: "The literature of the treatment of club-foot is, as a rule, that of unvarying success. It is often as brilliant as an advertising sheet, and yet in practice there is no lack of half-cured or relapsed cases, sufficient evidence that methods of cure are not universally understood. In all methods related to the treatment of club-foot, time and painstaking attention to the details of after-care are probably the most important factors in success.

An important stimulus has been introduced by Kite, of Decatur, Georgia. Severe operations necessarily entail considerable mutilation of the internal architecture of the foot. While such operations may give excellent cosmetic results, they almost invariably leave feet that are more or less permanently or recurrently painful. Kite proposed to first correct the deformity by slow conservative manipulations, without anesthesia. Each small correction is followed by a plaster to hold the new position. After repeated corrections over a period of time he found that the parts were susceptible to remarkable reformation. After maximum correction has been obtained, a period of observation is allowed. If a tendency to recurrence appears, the foot is surgically fused before the deformity appears. Under this method, a simple anthrodesing operation is sufficient to maintain correction, and more extensive surgery is no longer necessary.

The operative experience gained in the treatment of paralytic and congenital foot deformities has been applied to other foot disabilities. Numerous operations have been devised to overcome the malformation of rigid or exaggerated flat-foot, traumatic pes valgus, severe hallux valgus and other distortions. The present ingenuity applied to surgical procedures upon the bones of deformed feet is of temporary utility, since outstanding success follows only the proper early application of methods conceived for the prevention of bone deformity consequent to weight bearing.

Physiology

The physiology of the foot is concerned chiefwith the mechanics of weight-bearing and flexible locomotion. The structure of the foot furnishes spring to the step, which prevents jars to brain, spinal cord and abdominal and pelvic organs. Brown says the functions of the normal foot, which is certainly one of the most marvelous machines in Nature, are: weight-bearing during standing and locomotion, the provision of a spring to reduce jars and assist propulsion during movement, and action as a pivot to assist the turning of the body. There are few movements which do not combine all three of these. These functions do not depend entirely on the foot itself, but on the brain and spinal cord, so that an anatomically intact foot does not insure a perfectly functioning foot. The integrity of structure and function are not identical.

Disturbances of physiology involve mechanical stress and strain on muscles, ligaments and capsules of the bones and joints.

Two bones of great importance are the astragalus and os calcis; the former because it is the mortise bone between the leg and the foot. The astragalus articulates with the tibia, fibula and scaphoid. It articulates with the os calcis in three places. Although it cannot move itself, because it has no muscle attachments, it is subjected to the superincumbent weight of the entire body. The os calci is important because of its attachments for the achilles tendon and plantar fascia. It furnishes the initial bearing surface of the foot as it strikes the ground in walking. The scaphoid and first cuneiform bones owe their importance to the attachments of ligaments, and especially the tendons of the peroneus longus, and the anterior and posterior tibial muscles. The longitudinal arch is composed of the os calcis, astragalus, scaphoid, first and second cuneiforms, first metatarsal and proximal phalanx of the great toe. When a foot is in action it is supported chiefly by muscles, but when standing, chiefly by ligaments. Hoke emphasized the importance of three tendons: those of the anterior and posterior tibials and the flexor hallucis longus.

Terminology

The generic term for foot deformities is "talipes" derived from talus (astragalus) and pes (foot). If the toes are at a lower level than the heel, the term equinus is used; if the heel

is lower than the toes, the term calcaneus is used. In addition to either of these positions, if the foot is rotated on the long axis of the foot, the terms varus and valgus are used.

Inversion of the foot occurs when the inner border is elevated. Eversion occurs when the outer border is elevated. When a foot is inverted, there is a tendency for the fore part of the foot to approach the mid-line of the body, that is, adduction. This movement occurs chiefly at the tarso-metatarsal articulations. With eversion, there is a strong inclination to the opposite movement at these joints, namely abduction. When a foot is inverted and adducted, there is usually an upward and outward rotation of the medial bones of the mid-tarsal region, namely, the scaphoid, and the first and second cuneiform bones. This constitutes supination. If a foot is everted and abducted, the reverse occurs, that is, downward and inward rotation of the medial mid-tarsal bone, producing pronation. A foot that is inverted, adducted and supinated is in varus position, and a foot that is everted, abducted and pronated is in valgus position.

Shoes and Their Modifications

As a general proposition one may say that a shoe should be straight-lasted, round-toed, have a moderate height of heel and a rigid shank. It must be narrow in the heel and through the waist of the foot, but wide through the ball. There is comparatively little difficulty in obtaining proper shaped shoes for children and men; but for girls and women the matter is entirely different. Women are the victims of two things: one is style and the other is the shoe salesman. Women prefer to fit the eye rather than the foot and please the eye rather than their husbands. "There is no shoe too small for an ambitious foot."

Shoes are modified, for the most part, in the regions of the heels, soles, counters, and big toe. The chief modification of the heel is the Thomas heel, which is longer and higher on the inner than the outer border. This compels the individuals to walk over the proper walking angle so that a weight-bearing line dropped from the middle of the patella, bisects the tibia and the astragalus. The chief modification of the sole is the elevation of the outer border where the highest point of the wedge should be under the base of the fifth toe.

Modification of the counter includes the removal of the counter for irritation of the heel; and the prolongation of the counter on the inner border to protect and support the scaphoid, cuneiform I and base of the first metatarsal. Modification in the region of the big toe joint consists in a rigid sole to prevent motion in the big toe joint. This procedure may be beneficial in relieving the pain in cases of osteoarthritis of the big toe joint. The chief modification of the sole is what is known as a metatarsal bar or metatarsal cleat which consists of a strip of leather or rubber secured between the layers of the sole, at a point just behind the heads of the metatarsal bones. The so-called Denver bar is very effective.

Old Shoes

How much a man is like old shoes!
For instance, each a soul may lose.
Both have been tanned, both are made tight
By cobblers. Both get left and right.
Each needs a mate to be complete,
And both are made to go on feet.
They both need healing, they both get sold,
And both in time turn all to mould.
With shoes the last is first; with men
The first shall be the last; and when
The shoes wear out they're mended new;
When men wear out they're men dead, too.
They both are trod upon, and both
Will tread on others, nothing loth,
Both have their ties, and both incline,
When polished, in the world to shine;
And both peg out—Now, would you choose
To be a Man, or be his shoes?—M. C. Dodge.

AUTHENTIC BIOGRAPHIC DATA*

MONTE C. PIPER, M.D.

Rochester, Minnesota

THE constitution of the State Medical Association asserts that the purposes of the organization are the promotion of the science and art of medicine, the protection of public health, and the betterment of the medical profession.

The Council of the State Association adopted, last year, the new application blank for membership because sufficient record of the life histories of the members was not being maintained.

Mr. Ralph K. Lindop remarks in "The Legal Aspects of Records" that, "it may be safely laid down as a general principle that whenever there is a duty to do, there is also a duty to record the things done." John G. Bowman, Director of the American College of Surgeons, says that, "record means Authentic Evidence" and, as refers to hospitals, "the record department is directly responsible for the reputation of the hospital." Fred G. Carter adds, "Records protect the physician in his practice." Likewise, the Council felt that records would be of value in protecting the reputation of the medical profession.

There is much evidence of record of achievement in the progress of science and teaching but there is no systematic uniformity in recording the progress of the members of the profession as a whole. While a doctor is attending school and applying for licenses, numerous records are made. His qualifications are recorded in an exacting manner but after he has graduated and has become elected to membership in the Medical Association, there is no further uniformity or system of recording his progress and activities. He is turned loose, as it were, to practice his profession with the assurance that he is qualified and, unless he is outstanding in some manner, his identity may be all but lost. True, he is protected by the licensing board of the state and the state journal is sent to his address; his colleagues know of his activities to some degree but authentic evidence or record is no longer maintained.

The old application blank for Association membership contained very little information not included in the records of the licensing board and this new blank is only slightly more comprehensive than the old one, but it is a beginning, at least, for "the betterment of the profession." The new blank is designed to collect further historic and genealogic data and reveal something of the progress of each individual in medicine.

One is struck with wonder that, in the three thousand years of medical organization, there seems to be no evidence of concerted successful recording or compilation of the progress or failure of individual members. It is true that there is a vast amount of information about a few and much information regarding some physicians but there is certainly a paucity of information regarding many. Newspapers and magazine articles form the chief source of recorded data, but the doctor must "break into print" occasionally to be thus recorded. Large newspaper offices maintain very extensive reference libraries formerly called "morgues," some with as many as two million references. The American Medical Association has maintained a library of clippings and other information for thirty-two years. They have name cards with accumulated data concerning every doctor of whom they have ever had record and, now, there are accumulated about a million references. The library is admirably systematized, supervised, and kept alive, but its data come from printed or written reports.

The State Board of Medical Examiners is now keeping clippings and other data that their efficient office staff finds by searching publications. With the new application blank of the State Medical Association, each name is supplied with a large envelope in which all obtainable information will be filed. These, however, are only records of something remarkable enough to be printed or written about. There is no uniformity of purpose of these records except the accumulation of references.

Ramsey County Medical Society has compiled some biographic data and has a very fine album of photographs of many of its members. Hennepin County has photographs of all of its former presidents and attempted, for a time, to keep

*From the Section on Obstetrics and Gynecology, The Mayo Clinic, Rochester, Minnesota. Read before the annual meeting of the Officers of the County Medical Societies of the State, Saint Paul, Feb. 26, 1938.

a rather complete biographic record of all members but it has not been continued. The University of Minnesota Press has recently published "Physicians of The Mayo Clinic and The Mayo Foundation." This new volume contains the photograph and complete biographic and bibliographic data on all Members of the Staff of The Mayo Clinic and Fellows in the Foundation. No doubt, other groups have some system of keeping alive active records, but publications of these systems have not been found. The majority of members of the profession are unrecorded, perhaps throughout life, unless some event in their lives seems of sufficient importance to be "written up."

There is no uniform record of progress. Cities, villages, counties, and states do not attempt to maintain a measurement of the progress of professional men other than tabulations of qualifications. So far as has been ascertained, hospitals do not maintain a personal record of their staff except the professional qualifications and accomplishments of each member, if such pertain to the care of patients. The reputation and success of a hospital depends entirely on the quality of its staff members. One would suppose that hospital managements would be concerned about the health, the civil activities, the recreations and leisures and the families of so important a part of their organization.

The Medical School of the University is starting a five-year follow-up of its graduates to ascertain their successes and the shortcomings of their scholastic training. The General College of the University has made a critical survey of a group of graduates that preceded the depression and a similar group of students who have graduated since the depression to ascertain their attitudes toward the education obtained. This survey was made by use of a very comprehensive and painstakingly prepared questionnaire. It would seem that no better estimate of the usefulness of an education could be obtained than by those who have had an opportunity to apply that education to life.

Sir Richard Livingstone says there is a "threefold function of man: to make a livelihood, to be a citizen, to be a man . . . At present life is so arranged that most of us do our thinking in youth at an age when we are not best fitted for it, and having left the University think, systematically, no more. What wonder that middle life finds so many unaware of recent progress in their own field, unapt for new experiments and ideas, deeply embedded in a rut, while progress waits impatiently for their death and the arrival of the next generation . . . In every point except the economic one adult education has the advantage . . . It is given to students who desire it, who have the mental development to receive it, and have the experience of life to value and interpret it."

There are many members of the doctors' guild who are doing valiant work, are of much influence for progress and good example in their communities, who have the love and respect of those who know them and have success. Of these, there is very little, if any, written record. Such lives should contribute a part historically, for history is the study of change in humanity, the development of human society in space and time.

The historical committee has made diligent effort to assemble facts of medical history in this state over the approximate period of 1850 to 1900, and they have succeeded to a remarkable degree. Those who have undertaken the task must have given freely of effort and time. The records they are able to obtain of the pioneers are written records in some form or other. But a knowledge of others, of whom there is so little written or recorded, has vanished with the passing of the friends and relatives who remembered them.

The new application blank will contain a uniformity of data which will be available as a starting point or a foundation on which may be added further information of the past as well as of the future. It is the desire of the Council that all members of the Association fill in these new blanks as completely as possible. Data other than what is requested in the questions will add much more to their value. Some seven county societies have already completed these blanks in large numbers. Others have voiced objections to filling out another blank and, probably, that objection is largely due to a misunderstanding as to the use that is to be made of these blanks. Previous members are asked to comply, so that uniform biographic data may be obtained of all. Records exist of your training period. Why should there be objection to keeping record of your progress?

This new movement has, as its object, uniformity in recording; it should be dedicated to all of the profession, quoting Dr. Henry E.

Sigerist, "To the unknown doctor, who, in unselfish and inconspicuous activities, fulfils the teaching of the Great Doctors."

The great teachers are conspicuous and there is much record of them but there are great physicians whose contribution to the welfare of their communities should not go unrecorded. Assuming that this foundation is established by collecting the data of the new information blank, why should not the medical association, of which we are members, continue to record a system of progress and build a structure showing advancement on that foundation? It would seem that such a procedure would be of present-day value as revealing cumulative authentic evidence in the future of progressiveness of the profession as a whole.

Such evidence might be obtained by various methods, but the one which suggests itself at present as being the most feasible would be a survey at stated intervals, perhaps once every five years. It would be feasible because all members would participate in personally supplying the desired information. Dr. R. G. Leland, Director of the Bureau of Medical Economics, says, "A knowledge of the competence of the members of the medical profession should be of value primarily to the public—but this knowledge should be compiled by the profession itself."

A committee consisting of the chairmen of several existing committees and including those of medical education and of history together with others interested in the subject could compile a suitable questionnaire or invoice sheet. This committee, probably, would wish to obtain assistance in compiling that form from the medical school and other departments of the University. Such a questionnaire of census could be filled out by individual members with the understanding that personal identity be treated confidentially. Conscientiousness and integrity would be assumed in compilation by each member. It would be a coöperative method and each member would be requested to contribute to its compilation. Such an attempt to keep a record of progress would be a new venture entirely, for there seems to be no published evidence of such an effort previously having been tried or, at least, carried on. Such an investigation might reveal professional achievements, courses of study taken, participation in medical societies, honors attained, articles published, type of medical reading, value of certain journals, attitude toward preventative medicine, maternal and infant welfare, workmen's compensation and contract practices, hospital facilities, coöperation with other doctors, fitness for the chosen field or specialty, personal inspirations or inhibitions, civic activities and rewards, fluctuations in compensation, influence of relief problems, ancestors in the medical world or other geneologic factors influencing ambitions, progress of one's family, children studying or practicing medicine. Likewise, the investigation might reveal general achievements like recommendations of measures to advance the standards of medicine, improvements in medical school curricula by stressing some factors and curtailing others, postgraduate studies of practicing physicians, adult education, evaluation of fitness of some physicians in their field, health of doctors, occupational diseases, hobbies, recreations, trends, illness, and prevalence of hereditary influences on some diseases.

It is a sad commentary when cardiologists show that physicians succumb to hypertensive heart disease and coronary disease more frequently than those of any other vocation. The cumulative strenuousness and unremitting responsibility of the physician's life seem to be taking their toll of doctors. There are probably many other valuable factors which could be worked out. Supposing some such survey had been conducted over the past twenty-five years and included in its scope twenty-five to fifty thousand physicians. There could be evolved from statistical study of such records answers to many of the criticisms which have been aimed at the medical profession by some members of the medical profession and by the social reformers of recent years. The officers of the American Medical Association would, no doubt, welcome such information if it were available.

The success of such a survey or questionnaire would depend on the ease with which the questions could be answered. If they could be answered readily, without too much trouble, most men probably would be willing to fill out the blank. If questions were cumbersome and involved, many probably would defer answering them, and, finally, forget to answer them. But, if it is to be a record of progress, it would have a certain appeal.

Doctors should be qualified to keep records. It is important regarding the care of the patients and should be important to one's own life. When the American College of Surgeons, in 1913, required the records of 100 cases in order to qualify for membership, it afforded stimulus to hospitals and physicians to keep accurate records and these records have been an invaluable stimulus in the furthering of medical studies.

The recording of the individual physician's activities will also be of great aid to future historical committees. Much information of this nature is disappearing as the older generation passes on and it should be collected while it is still available. The historical committee cannot reach it all.

There is an organization which could render very valuable assistance, if it could be prevailed on to undertake the task. Our wives are organized as Women's Auxiliary and, if they would undertake to collect this information, it would be a valuable assistance and, assumedly, an enjoyable project for their activities.

Perhaps some form could be supplied with an individual physician's name and address filled in and this could be allocated to the Auxiliary of the respective county unit. No doubt the historical committee would welcome such assistance.

NUTRITION IN PREGNANCY*

RUSSELL J. MOE, M.D.

Duluth, Minnesota

IN spite of much valuable laboratory and clinical research on the problem of nutrition in pregnancy, it is only within recent years that we have begun to apply these findings to obstetrical practice. We, as practitioners, have failed to give proper attention to the dietary requirements during pregnancy. In view of the fact that an adequate protective diet is an important part of good prenatal care, it behooves us to give this problem the attention it rightly deserves.

It is an accepted fact that many of the complications and disabilities associated with pregnancy, labor and lactation are due directly or indirectly to improper or inadequate nutrition. This often begins in the early prenatal period, especially with multiparous, overworked women, and with women who are naturally substandard or chronically undernourished. There are still some misconceptions among medical men as to what constitutes the nutritional needs of the pregnant state. In general, this question may be answered by the statement that the mother should be supplied with the various foods necessary for her own metabolism, and in addition, those needed for the growth and development of the fetus.

Foods may be considered under two main types: (1) the "protective" foods, consisting chiefly of those containing "good" protein, minerals and vitamins; (2) the "energy-bearing" foods, such as carbohydrates and fats. The ideal diet includes sufficient "protective" foods to prevent the development of deficiency diseases, as well as the proper proportion of "energy-bearing" foods, to maintain the growth and activity of the body. Actual starvation from lack of sufficient calories is practically unheard of today. The real danger lies in the fact that individuals in the low income group are forced to substitute the lower priced carbohydrates for the higher priced foods containing protein, minerals and vitamins.

Protective Foods

The highly protective foods include milk, cheese, eggs, meat, butter, fresh green vegetables and raw ripe fruit. Sunlight may also be considered an adjunct to the above list, because it generates vitamin D in the organism. The value of milk as a food for pregnant and lactating moth-

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

A. Protective Foods:

Food	Amount	Protein	Calcium	Phosphorus	Iron	Iodine	Vitamin A	Vitamin B_1	Vitamin B_2	Vitamin C	Vitamin D	Calories	Remarks
	Grammes				Milligrammes		International Units			International Units			
Milk	1,000	32	1.2	0.9	2.4	0.02—0.05	Rich (1,000-3,000)	Good (50-75)	Rich	Poor	Poor	660	(a) Calculations for lean meat.
Meat (or fish or poultry)	120(a)	22	—	0.3	5.0 / 2(a_1)	—	Poor	Poor(b)	Rich	Poor	None	240	(a_1) One-half calculated as available iron.
Eggs (one).....	50	6	—	0.1	1.5	—	Rich (1,000-1,300)	Good (about 15)	Rich	None	25-40	70	(b) Except glands (liver and kidneys) and pork muscle.
Cheese (c).....	30	8	0.3	0.2	0.4	—	Rich (800-1,000)	Poor	Good	Poor	Poor	125	(c) Calculated as cheddar cheese.
Green and Leafy Vegetables	100(d)	1	0.1	—	1.2	—	Rich (1,000-1,500)	Good	Good	Poor	None	30	(d) Estimated on basis of ⅓ cabbage, ⅓ lettuce, ⅓ spinach.
Potatoes	250	6	—	0.2	2.0	—	Poor	Good	Good	Good	None	250	
Legumes, Dried....	10(e)	2	—	—	0.2	—	Poor	Good	Good	None	None	35	(e) Calculated as beans.
Cod Liver Oil.....	3.5	—	—	—	—	Richest source	Rich (1,800-3,500)	None	None	None	Rich (about 300)	30	
An available source of Vitamin C (from raw fruits and vegetables)..										To yield 250-500			
Total Yield...		77	1.6	1.7	10.2	Adequate	Over 5,000	Over 150	Adequate	Over 500	About 300	1,440	

B. Supplementary energy-yielding foods by means of which the individual's energy requirements can be met.

Cereals as needed:													
Highly milled....	250(f)	28	—	0.2	2.5			Rich (about 250)				1,000	(f) Calculated as white flour.
or Whole Grain..	250(g)	—	0.1	0.9	9.0							1,000	(g) Calculated as whole wheat.

Fats as needed.
Sugar as needed.

The estimates are based on data in Sherman's "Chemistry of Food and Nutrition," 4th edition, 1933. The figures for milk are calculated for a content of 3.2% protein and 3.5% fat. The figures for vitamins, however, are converted to international units and must be regarded as rough approximation only.

TABLE I. NUTRITIVE VALUE OF FOODS[4]

Food	"Good" Protein	Minerals	A	B	C	D

ers is well recognized. A committee report of the League of Nations on the relation of nutrition to health states that the use of the milk from cows or other mammals in the diet of the human race is as old as the history of mankind, and during the long ages in which it has been thus used its value has ever been highly esteemed. A land "flowing with milk" was the ideal of pastoral tribes in ancient times, and will still remain the ideal if the balancing of nutrition and health of the people receive due consideration. The report continues with the statement that modern scientific research has entirely confirmed the empirical conclusion drawn from human experience as to the dietary value of milk. Milk, which is designed to afford complete nutrition to the mamalian young, is known to contain all the factors needed for satisfactory nutrition, combined in a suitably proportioned mixture of protein of "good" quality, fat, carbohydrate, mineral salts and vitamins. In this respect, milk is the nearest approach we possess to a perfect and complete food. No other food that can be used as a substitute is known. The administration of calcium in any form or dosage cannot completely replace milk. The patient who will drink one quart of cow's milk daily during pregnancy and lactation will satisfy her calcium and phosphorus requirements in a form which is especially easy of absorption and assimilation. In addition, she will obtain valuable protein food, in the form of lactalbumin and casein, both of which are not only present in large quantities but possess a highly nutritive value. We must also be mindful of the fact that in milk there is no loss of protein by cooking, such as occurs with the protein of muscle meats.

The vitamin content of cow's milk varies with the seasons of the year. However, the reduction of vitamin D in winter milk is easily overcome by the daily administration of two or three teaspoonfuls of cod liver oil or its equivalent. It is neither necessary nor desirable to give large doses of cod liver oil or its concentrates routinely to pregnant women. Vitamins are not a panacea for all the ills that beset women during pregnancy. Just as in all other conditions, judgment must be used in their administration. Naturally, associated fever or vomiting may call for special measures and larger dosages until equilibrium is attained. There is accumulating evidence to the effect that increased ossification of the fetal

skull, leading to a higher incidence of dystocia, may be due to excessive calcium and vitamin therapy.

It should be understood, however, that certain women present more or less chronic deficiences of iron, protein and vitamins; and just as they need large doses of iron so a few may need, temporarily at least, large doses of vitamins. If we simply evaluate the condition of the tongue, the fingernails, in association with determining the presence or absence of free hydrochloric acid in the stomach and the hemoglobin level, we gain a valuable estimate of our patient's dietary efficiency.

Cheese, which may be considered as concentrated milk, contains the "good" protein, as well as the calcium salts and vitamins of milk. Small portions of cheese may well be included in the diet two or three times a week. Butter is a valuable food, because it is composed of the most easily digestible fat, and is an additional source of the fat soluble vitamins A and D.

Eggs are another important source of good protein, as well as valuable minerals and vitamin B. They are usually well tolerated, and may be prepared in a number of ways to entice the individual who will be benefited by them.

While ordinary muscle meat is inferior to milk or eggs in nutritional value, it does serve as an important source of protein and iron. We are all aware that many of our patients are instructed by their lay advisers to eat little or no meat during their pregnancy. The results of these curbstone consultations are undoubtedly reflected in some of the anemias seen during pregnancy. It is estimated that two grams of protein per kilo of body weight are needed by the maternal organism and the growing fetus. The daily requirement of protein for the patient of average weight would therefore be between one hundred and thirty and one hundred and fifty grams. Furthermore, all this should be absorbed. Liver, kidney and sweetbreads have a logical use, since they are rich in minerals and vitamins not found in muscle meats.

Green leafy vegetables and raw ripe fruits are highly acceptable, particularly because of their vitamin A and B content. They also contain the antiscorbutic vitamin C if taken in the uncooked form. The abundance of minerals adds greatly to the value of vegetables and fruits. Calcium is present in oranges, while grapes and apricots are rich in iron.

In many parts of the world it is desirable to complement the vitamin intake, especially during the winter and spring months, by the administration of cod liver oil or other fish liver oils. Some of the vitamins taken by the patient will be lost, however, if she routinely uses mineral oil to overcome constipation. The fat soluble vitamins A and D are soluble in mineral oil.

While a patient may have an adequate intake of vitamins, the constant presence of mineral oil in the bowel may cause that patient to have a deficiency. As a result of the absorption of vitamins by the mineral oil the amount available for metabolism is utilized only in part.

In goitrous regions it is advisable to recommend either the use of iodized salt or two to three minims of Lugol's solution a week.

Energy-bearing Foods

The energy-bearing foods include cereals in their various forms, sugar, potatoes and fats. These foods should be added to the protective foods in a quantity sufficient to satisfy the energy requirements during pregnancy. An analysis of the cereal foods reveals that many of their valuable elements are lost in the process of milling. White flour, for instance, is rich in carbohydrate but lacking in the B vitamins contained in the husk and germ of the grain. There is also a definite reduction in the mineral content of the highly milled grains when the bran and germ are cast off. The accompanying table shows clearly the relatively large amounts of minerals in wheat bran and wheat germ as compared with those in white flour. A finely textured white bread is produced at the expense of these valuable constituents.

It is apparent that there is some variation in the value of the different carbohydrate foods. Sugar and milled cereals predispose to dental disease when introduced to people in remote districts or countries where tooth decay was previously unknown. Contrary to popular belief, potatoes are of distinctly more value than sugar or milled cereals, in that they do not predispose to dental caries. In addition, they are a valuable source of iron, and, according to some authorities, retain a high proportion of their vitamin C content even after cooking. Certainly, the balance of evidence indicates that we are not solv-

TABLE II. MINERAL COMPOSITION BY WEIGHT OF WHEAT AND WHEAT PRODUCTS[7]

	Whole wheat	Wheat flour (white)	Wheat bran	Wheat germ
Potassium ...	0.473	0.115	1.217	0.296
Sodium	0.039	0.060	0.154	0.722
Calcium	0.045	0.020	0.120	0.071
Magnesium ..	0.133	0.018	0.511	0.342
Phosphorus ..	0.423	0.092	1.215	1.050
Chlorine	0.068	0.074	0.090	0.070
Sulphur	0.005	0.177	0.247	0.325
Iron		0.001	0.008	

ing the problem of dental caries by the administration of excessive amounts of calcium and vitamin D. Proper dental hygiene and eating of foods that require more chewing seem to be the factors which promote alveolar circulation and dental metabolism.

Another factor in the dietary management of a pregnant woman is the observation of the weight curve. A woman of normal weight is expected to gain from twenty-five to thirty pounds during her pregnancy, while a woman who is overweight to start with should be expected to gain less than that amount. Conversely, a woman who is underweight may well gain more than thirty pounds. By recording the average weight of the patient before her pregnancy and the weight at each prenatal visit, the physician is readily made aware of any abnormal weight gain, which will indicate one of two conditions: either an abnormally high carbohydrate intake, or an impending toxemia with its disturbed water metabolism.

The size of the fetus apparently is not affected much by the weight gain of the mother. Our present evidence indicates that the mother's metabolic rate may be a more important factor in determining the weight of the baby.

Summary

1. The diet of the expectant mother should include a quart of whole milk daily, to furnish the necessary calcium and phosphorus as well as "good" protein and vitamins.

2. A generous helping of meat is necessary for an adequate protein intake. The lay and medical advice to avoid meat has been very pernicious.

3. Eggs and cheese will furnish additional protein and valuable minerals.

4. Fresh leafy vegetables and raw ripe fruit are necessary for their vitamin and mineral content. The vitamin needs should be determined for each individual.

5. The vitamin content of the diet should be conserved by avoiding the routine use of mineral oil.

6. In goitrous regions small doses of iodine are valuable adjuncts to the dietary.

7. The substitution of coarse cereals and potatoes is to be recommended to replace the highly milled cereals and sugars.

8. Small doses of cod liver oil are of definite value during the winter and spring months.

9. The routine use of large doses of calcium and concentrated vitamins should be condemned.

10. Observation of the patient's weight during pregnancy will indicate excessive gains, as well as give warning of impending complications.

Discussion

Dr. E. C. Hartley, Saint Paul, (read in his absence by Dr. V. O. Wilson): Doctor Moe has reviewed concisely the important points to be considered in the nutrition of the expectant mother.

In my discussion I wish to draw your attention to two points which are significant.

First: The subject is one of more importance than would appear to the casual observer. The studies of the Mixed Committee of the League of Nations bear witness to the far-flung bearing which nutrition has on health, on agriculture and on the economic policy of nations. Its more intimate relations to health are the immediate concern of a growing number of publications devoted entirely, or in part, to the complex relationship between nutrition and health.

Second: The importance of nutrition reaches its peak in the pregnant woman. Here the protective and the growth factors in nutrition have their greatest significance. Our point of view here is both absolute and relative. The absolute requirements of the pregnant woman as compared to the non-pregnant woman are summarized in a chart from the League of Nations "Report on the Physiological Bases of Nutrition."

By relative requirements I mean those individual variations which the physician so frequently meets, and which he should recognize so that he may guide the patient in the necessary adjustments in her diet.

Dietary deficiencies in the pregnant woman may be due not only to a failure to eat the proper foods in adequate amounts. It is often due to a failure to utilize such foods after they are eaten. In either case there are usually clinical signs obvious enough to guide the

physician in correcting the deficiency. I agree with Doctor Moe that the indiscriminate use of calcium and vitamin D in pregnancy is neither desirable nor necessary. It is equally true, however, that the calcium requirements of every pregnant or nursing mother cannot be met by the classic dole of one quart of milk daily. The need for extra amounts of calcium is indicated by definite clinical signs. So, also, are the needs for extra amounts of iodine, or of iron.

The protein requirements of the pregnant, and especially the nursing mother, are of great importance. Meat and eggs should be included on an equal plane with milk, and there is no great urgency in curtailing them too drastically at the first sign of toxemia.

The response of individuals to pregnancy, as we all know, is exceedingly variable. This variability extends to their nutritional needs, and we must be ready to recognize this variability and to adjust our patients to such a standard as will be optimum in individual cases.

INFLAMMATORY LESIONS OF THE CERVIX AND VAGINA*

LEE W. BARRY, M.D.

Saint Paul, Minnesota

TO the physician, the different inflammatory lesions of the cervix and vagina are oftentimes of minor importance. This is not the viewpoint of the patient. The resulting pelvic discomfort and especially the leukorrhea drive her from doctor to doctor in search of a cure. The constant vaginal discharge violates her ideals of cleanliness. She longs for the day when she can dispense with douches and the constant wearing of a sanitary napkin. The physician who affects a cure renders a worth-while service by restoring her health and happiness as well as her waning confidence in the medical profession.

The inflammatory lesions of the cervix, which will be considered, are cervicitis and endocervicitis (acute and chronic), the various erosions, cystic changes, lacerations, eversions, ulcerations, polypi and hypertrophy.

Injuries to the cervix during childbirth and gonorrhea are the two greatest causes of cervicitis and endocervicitis. Inflammation of the cervix may be classified as acute, sub-acute and chronic. In acute cervicitis, treatment should be restricted to a minimum, reliance being placed mainly upon cleanliness. Treatment with strong chemical solutions or with a thermal cautery should never be attempted. The cervical canal should not be invaded, because of danger of carrying infection into the uterine cavity with subsequent tubal, ovarian, or peritoneal involvement.

At the present writing, sulfanilamide is popular in the treatment of acute gonorrhea. Orr[13] treated thirty females with sulfanilamide, with cures in 26, or 86.6 per cent, of the cases. No local treatment of any kind was given. For the first four days, eighty grains of sulfanilamide were given in twenty grain doses, every four hours, from 8 a. m. to 8 p. m.; forty grains daily were given for the next four days, and the doses were then reduced to twenty grains daily for the following seven days. The total dosage of sulfanilamide given to each patient was 620 grains during a period of fifteen days. In all the cured cases, smears became negative within two weeks. Many other writers have reported similar results, which would seem to indicate that sulfanilamide is a very valuable drug in the treatment of acute gonorrhea in the adult female.

The use of the Ferry-Corbus filtrate[3] is still an unsettled procedure. The hyperpyrexia of Bierman and Horowitz,[2] Desjardins,[6] Stuhler,[16] et al, has cured gonorrheal cervicitis, in 45 to 86 per cent of the cases, but the treatment is not without danger and requires a corps of well trained attendants to constantly watch the patient while a rectal temperature of 106 to 107 degrees is maintained for four to six hours. To obtain a cure the treatment must be repeated four or five times, at intervals of three to four days, at the end of which time the patient begins to wonder which is worse, the disease or cure.

Just what proportion of acute cervical infections become chronic is difficult of determination. However, it may be stated that practically a third of the women who visit the gynecologist do so because of a chronic endocervicitis.

Chronic cervicitis, endocervicitis, the chronic cervical erosions of whatever variety, and the cervical ectropions, may be treated with 50 per cent phenol, 5 to 30 per cent silver nitrate solution, zinc sulphate, either in a strong solution or by means of a zinc sulphate saturated porous pencil introduced into the cervix. All of the above treatments, result in a fair percentage of cures. Tincture of iodine, mercurochrome, argryol and

*Read before the Annual Meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

ichthyol have been proved to be practically worthless.

In the last decade the treatment of the above conditions has been fairly well standardized in nearly all the large gynecological clinics. This standard treatment consists in linear cauterization of the cervix with a fine nasal tipped electro-thermal cautery. Incisions are made in the cervix with a cautery tip about one-fourth of an inch apart. The incision is begun in the cervical canal, one-half inch from the internal os, and is prolonged well over the outside of the cervical lip until it reaches the normal vaginal epithelium. If properly performed, one cauterization results in a cure in approximately 80 percent of the cases. Surgical diathermy with its more expensive equipment and more complicated technic gives about the same percentage of cures. After cauterization, the cervix should be observed at weekly intervals for about three months. Cervical stenosis may be prevented by keeping the cervix dilated up to 4 mm. at monthly intervals for one year after cauterization. The first one or two menstrual periods after cauterization may be very profuse, but this rarely ever results in any serious consequences. Cauterization of the cervix is contra-indicated: (1) where there is an acute infection of the cervix; (2) immediately before or immediately following a supra-vaginal hysterectomy; (3) in the presence of an acute or sub-acute salpingitis; (4) during pregnancy or within six weeks following delivery.

Nabothian cysts are best treated by puncturing the cyst with the cautery tip, pressure being exerted until the whole cyst cavity is thoroughly cauterized.

Lacerations of the cervix should not be repaired in the presence of an existing inflammation; too often, the diseased portion of the cervix is rendered inaccessible to treatment as a result of the surgical repair. Cure the cervicitis first and repair the cervix later.

Ulcerations of the cervix are simple, chancroidal, syphilitic, tuberculous, and malignant. Simple ulcers are rather obscure as to their origin and a cure is usually spontaneous without treatment. The chancroidal ulcer, due to Ducrey's bacillus, is usually multiple; the margins are ragged and undermined. Treatment with pure formalin is a specific.

Primary syphilitic ulceration of the cervix occurs more frequently than is generally suspected. The ulcer is round, slightly depressed, and is surrounded by a white wheal-like area at the periphery. Leutic secondaries cause shallow ulcerations of the cervix which are very fleeting in character. They often disappear spontaneously in the course of a week or ten days. Tertiary syphilitic ulceration of the cervix may occur from five to forty years or more after the primary lesion, resulting frequently in a massive sloughing of the cervix and surrounding tissues. Diagnosis is best confirmed by finding the spirochetæ pallida in any of the above lesions. In the presence of the primary and tertiary ulcers the Wassermann reaction is usually negative. If the lesion is syphilitic, constitutional anti-leutic treatment should be instituted at once.

Tuberculosis of the cervix is rare and is usually secondary to tuberculosis elsewhere in the genital tract. The four forms of cervical tuberculosis are: the miliary, ulcerative, papillary, and interstitial. Diagnosis is confirmed by biopsy. Treatment by cautery or surgical removal of the lesion results in a cure in about two-thirds of the cases. Radium and x-ray have been used with considerable success. Many clinicians, however, maintain that in tuberculosis of the cervix panhysterectomy is still the treatment of choice.

A biopsy is indicated in any cervical ulcer which fails to react to treatment. Many ulcers apparently inflammatory in character are proved by the microscope to be malignant. The microscope is many times more accurate than the most accomplished clinician.

Cervical polypi occur in the cervical canal at any age. They usually result from a chronic cervical discharge. Quite frequently they are multiple. When removed, their bases should be cauterized. All polypi should be examined microscopically, as a certain proportion are malignant. The incidence of malignancy increases with the age of the patient. To rule out malignancy, absolutely, it is a good policy to curette the uterus after the removal of a polypus, and have the curettings examined by a competent pathologist.

Hypertrophy of the cervix results from a chronic cystic and interstitial inflammation of the cervix. The cervix may reach enormous proportions, at times almost filling the vagina. Treatment is by electrical conization or surgical

amputation. In conization, one may employ either Hyams'[11] or Crossen's[4] technic. In amputating, one may use the Sturmdorf or the Schroeder operation. Sloughing and alarming postoperative hemorrhage are not uncommon after the latter operation. These complications may be minimized by using non-absorbable sutures, cutting them long, and delaying their removal until the fifteenth to the twentieth postoperative day.

Inflammation of the vagina may occur in a localized, acute or chronic form, giving the mucosa a spotted or mottled appearance; or the process may be diffuse. Although containing no glands (excepting Bartholin's and Skene's glands), the vaginal mucosa, when inflamed, exudes an acid transudate varying in amount and consistency.

Considering the proximity of the vagina to the irritating discharges from the urethra and rectum, and also the trauma to which it is subjected in childbirth, coitus, surgical procedures, and discharge from the cervix and uterus, one wonders that vaginitis is not more frequent. This immunity to infection is largely dependent upon the nature of the lining epithelium and its acid secretion.

Vaginitis may be caused by the various pyogenic cocci and bacilli, the micrococcus catarrhalis, Vincent's bacillus, Ducrey's bacillus, the tubercle bacillus, the diphtheria bacillus, various saprophytes and yeasts, and at least one protozoan, the trichomonas vaginalis.

In adults, the vaginal mucosa is strongly resistant to gonorrheal infection. This is not true in young girls up to ten years of age, in whom the gonococcus is the most common cause of vaginitis. In schools and institutions, gonorrheal vaginitis frequently assumes epidemic proportions. Sporadic cases are also frequent.

Hess,[7] in 1916, Stein, Leventhal and Sered,[15] in 1929, and Reichert,[14] in 1937, found an involvement of the cervix in these young girls in as high as 98 per cent of the cases, and suggest that the condition be termed cervicovaginitis rather than the commonly used vulvovaginitis, but TeLinde,[17] in a recent paper, claims that involvement of the endocervix is comparatively rare clinically.

Local treatment with 1 per cent of silver nitrate in equal parts of vaseline and lanolin injected into the vagina affords a high percentage of cures; 1/1000 merthiolate cream has been used with a great deal of success. If the cervix is involved, metaphen 1/500, 2 per cent acriflavine, or 1 per cent silver nitrate solution may be applied through a Kelly cystoscope.

Estrogenic hormones in doses of 1,000 international units, hypodermically, tri-weekly, give good results. Vaginal estrin suppositories containing 1,000 I.U. of amniotin have been found superior to the hypodermic injections, according to TeLinde.[17] Some clinicians think the cure results from a thickening of the vaginal mucosa; others, to an increase in the acidity of the vagina. Excellent results have been obtained by Karnaky[12] with the use of Floraquin-Searle tablets. Daily introduction of two or three tablets into the child's vagina can be done by the mother at home. This necessitates only weekly visits on the part of the child to the doctor's office. Good results are attributed to the maintenance of the vaginal pH at 4, which acidity favors the growth of Döderlein's bacillus and inhibits the growth of the gonococcus.

Hoffman, et al,[10] at the Cook County General Hospital, treated a group of twenty-five children, suffering from acute vulvovaginitis with sulfanilamide in daily dosage of ¾ grain per pound of body weight, in four equally divided doses every six hours for two days, after which the dosage was gradually diminished. They report seven of the twenty-five cured in an average of 17.3 days, and nine in an average of 42.9 days. Only two of the nine remaining patients were cured by further administration of the drug. None of the children (aged three months to ten years) suffered any toxic reactions.

In the last fifteen years, the trichomonas vaginalis has assumed an important rôle as the cause of vaginitis. It has been variously estimated that from 15 to 40 per cent of the cases of vaginitis are caused by this protozoan. Considerable controversy exists as to the exact causative agent and its origin. Clinically, with a trichomonas vaginalis infection, the discharge is foamy, bubbling, and greenish yellow in color and has a sweet odor. There are small reddened punctate areas throughout the vagina, and the cervix is reddened to such an extent as to be designated as a strawberry cervix. Probably, no other genital infection has been treated with such a multitude of remedies. Hesseltine[14] has recently studied the curative effect of three arsenical, one silver picrate, and two lactose preparations, and found that cures resulted from any of the preparations, in 85 to 90 per cent of

the cases. He claims superior results in a series of his cases from the introduction of one tablespoon of a powder, consisting of 95 per cent lactose and 5 per cent citric acid into the vagina after it has been wiped dry. The patient is instructed to insert a 30 grain tablet of this mixture into the vagina each night upon retiring.

At the University of Minnesota Health Service the routine followed in the treatment of trichomonas vaginalis consists of 5 grams of silver picrate powder (Wyeth) insufflated into the vagina after a thorough cleansing with hydrogen peroxide solution. The patient is instructed to insert a 2 grain suppository of silver picrate into the vagina each night for six consecutive nights. The patient then returns for another insufflation, again followed by suppositories for six nights. Winther[18] reports a cure in all of the twenty cases studied, with no recurrence for six months following treatment.

To Hesseltine, Borts, and Plass[9] must be given credit for calling our attention to the frequency of mycotic infections of the vagina. Perhaps 10 per cent of the cases of vaginitis are due to the two yeast organisms: the oidium albicans and the monilia. Yeast infections are very common in diabetes and in pregnancy and may persist for some time after delivery. The discharge is scanty and there are areas of involvement of the vaginal wall which have the appearance of cottage cheese. Itching is intractable and is the predominant symptom. Painting the vagina with Lugol's iodine solution in 0.25 to 0.5 of 1 per cent solution is almost a specific; a 1 per cent solution of gentian or crystal violet also yields excellent results.

Senile vaginitis develops after the menopause. The cause is unknown. The vagina is chronically inflamed. The walls bleed easily, and ulceration with adhesions often exist. Davis[5] has treated this condition with hypodermic injections of 100 rat units of estrogenic hormone two to three times a week, together with an additional 75 units, introduced daily in the form of vaginal suppositories. A cure usually results in two to four months. Adair and Hesseltine[1] report similar results with 95 per cent lactose and 5 per cent citric acid powder treatments given in the office at intervals of one to three weeks, together with the daily introduction at home by the patient of 1 to 2 gram pills of the same preparation.

Conclusions

1. The two most common causes of cervicitis and endocervicitis are injuries during childbirth and gonorrhea.

2. Sulfanilamide in appropriate dosage apparently effects a cure in acute gonorrheal cervicitis and vulvovaginitis in a high percentage of cases.

3. Hyperpyrexia effects a cure in 45 to 86 per cent of the cases in acute gonorrhea. The objections to this form of treatment are the danger of collapse on the part of the patient, the expense of the apparatus used, and the number of attendants necessary.

4. About one-third of the patients who visit the gynecologist do so because of chronic cervicitis. Cure is best obtained by linear cauterization of the cervix. Tincture of iodine, mercurochrome, argyrol and ichthyol have been proved to be practically worthless.

5. Lacerations of the cervix should never be repaired in the presence of existing inflammation.

6. Hypertrophy of the cervix may be treated by conization or amputation.

7. Estrogenic hormones in doses of 1,000 I.U. in vaginal suppositories, introduced daily, have been found to be superior to hypodermic injections of the same substance in the treatment of vulvovaginitis. Maintaining the vagina acidity at a pH of 4 or less, with Floroquin-Searle, as recommended by Karnaky, also gives good results.

8. Trichomonas vaginitis responds to treatment with citric acid and lactose preparation, or to silver picrate.

9. Iodine in the form of Lugol's solution is a specific for the monilia and oidium albicans infections of the vagina.

10. Senile vaginitis, may be treated with estrogenic hormones or citric acid-lactose preparations.

Discussion

Dr. W. F. Mercil, Crookston: On entering into the discussion of Dr. Barry's paper, one feels that his admonition to concern ourselves very definitely with the causation and proper treatment of leukorrhea is a timely one. The mere suggestion to the female to "take a douche for your discharge" is not satisfactory to the more exacting woman of this day. Certainly, a thorough investigation, the determination of the etiology, and the proper applications of the new and old principles of therapy are essential factors in maintaining the proper confidence of the laity in our profession.

Acute gonococcal cervicitis and endocervicitis is not commonly seen in the early stage. Most patients seek medical attention after a six weeks period, when smears are usually negative. The incidence of this acute disease in the female has been reduced markedly in the past ten years in our locality. The high doses of sulphanilimide seem to be the most effective. The use of local applications in chronic cervicitis, endocervicitis, and eversions of the cervix has been quite disappointing. Linear cauterization with the thin nasal cautery tip has been routinely employed with good results. One must bear in mind the possibility of lesions higher up in the female genital tract, and not treat too readily the more obvious cervical lesion. Crossen leans to the idea that conization will be the accepted method of treatment in the more intensive cervical lesions.

In the diagnosis of various inflammations of the cervix and vagina, the appearance of the local lesions may be quite similar and our clinical impressions do not coincide with the laboratory findings. I believe this to be especially true in the cases of trichomonas vaginitis. One sees a patient with the symptoms of burning and itching and an irritating odorous discharge. On inspection, one may see the chafing of the inner thigh regions and vulva, and further, the typical, foamy, yellowish discharge, with redness of the vaginal wall, and fail to find the trichomona on repeated hanging drop preparations. Douches taken as early as twenty-four hours before examination will often be the cause of our failures in establishing a microscopic diagnosis. Repeated infections, or reinfections, may be due to poor hygiene. We instruct our patients to wipe the anus from front to back in an effort to prevent reinfection of the vagina from the anus. The growing number of reports in the literature of trichomonas in the male genital tract of interest, and reinfection from that source should not be overlooked. The urinary bladder is also to be considered as a possible source. Catheterized specimens of urine have been shown to contain the trichomonas in as high as 10 per cent of cases.

This brings us to the problem of curability of this disease. We can assure our patient of relief from symptoms temporarily, and in some cases get seemingly permanent benefits; but, in my experience, in the great majority of cases there is either a reinfection or a return of the previous infection. One hesitates to assure the patient of a permanent cure on the basis of the present methods of therapy. Insufflation with silver picrate, or Devegan powders, have been most effective. Care should be exercised to avoid too strenuous insufflations during pregnancy.

Yeast infestations are more common in pregnancy. The intense itching, if not due to the trichomonas, can usually be traced to the monilia infection. In our series, 1 per cent solution of gentian or crystal violet were applied locally with good results. In two cases, no definite benefit was obtained until local water-cooled ultra-violet applications were used, and with three treatments all symptoms and local inflammatory reactions subsided. This method of therapy would seem to be of benefit in certain highly resistant forms of yeast infections.

In the treatment of senile vaginitis, we prefer the local instillation of estrogenic suppositories, rather than its hypodermic use as this seems to be sufficient in most cases.

OBSTETRIC HEMORRHAGE*

ROY E. SWANSON, Ph.D., M.D.

Assistant Professor of Obstetrics and Gynecology, University of Minnesota

Minneapolis, Minnesota

IN the last few years, both the medical profession and the lay people have shown an ever increasing interest in maternal mortality. The recent excellent maternal mortality rates reported for Minnesota are to be taken, we hope, as a measure of better and more conservative obstetric practice in this state. It can be said, without fear of contradiction, that much of the credit for this trend is due to the type of teaching given by our retiring chief, Jennings Crawford Litzenberg. For many years, he has taught a most conservative type of obstetrics; and nothing could be more fitting than to have his last year at the University marked by the lowest maternal mortality rate in the history of the state.

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

Among the outstanding causes of death in pregnancy, labor and the puerperium are sepsis, toxemia and hemorrhage. Hemorrhage and sepsis are very closely correlated in many cases, since the factors causing hemorrhage are many times factors in fatal sepsis. Sepsis which otherwise would not have resulted fatally may, if preceded by severe hemorrhage, lead to death. Sepsis so often results from meddlesome interference or major operative procedure with consequent abnormal blood loss and trauma, and so often follows toxemia, that it is difficult to evaluate the part each one plays in many deaths.

The recent and at times brilliant results that sulfanilamide has given in the treatment of puerperal sepsis will probably reduce the fatalities from this cause and will give hemorrhage a higher rate as a cause of death in labor.

The prevention and prompt treatment of hemorrhage should help to reduce maternal mortality. All procedures which are associated with the possibility of obstetric hemorrhage should be approached with the greatest caution even though methods for its treatment are immediately at hand.

Obstetric hemorrhage can most easily be discussed under the following headings: abortion, ectopic pregnancy, placenta previa, ablatio placentæ, and postpartum hemorrhage.

Abortion

Approximately 25 per cent of all maternal deaths are due to abortion. The criminal abortionist plays a large part in this with the introduction of infection and his refusal to take part in the treatment of subsequent hemorrhage. Sepsis, of course, plays a leading rôle. Death from hemorrhage following abortion should be rare, yet it causes about 10 per cent of deaths due to abortion. Prompt reporting of any bleeding in early pregnancy will save many lives. Facilities for curettage, packing the uterus and blood transfusions are essential. A firm stand on the part of the medical and legal professions in opposition to the professional abortionist would reduce maternal mortality in the United States by thousands yearly. Recent advances in the teaching of birth control will do much to avoid unwanted pregnancy. In time, it will cause a marked reduction in induced abortion. Spontaneous abortions are much better cared for since these patients are in most instances under adequate care. In the criminal abortion, however, the patient is as a rule away from home and friends, and is in no position to get good medical care until she is in extremis.

Litzenberg's classification of abortions into the decidual stage of pregnancy; the attachment stage of the placenta; and third, the placental stage, offers help in the treatment of this condition. In the decidual stage, present during the first six weeks of pregnancy, an abortion is likely to be complete with little bleeding, and curettage is rarely indicated. During the second six weeks, good attachment has taken place and an abortion at this time often causes hemorrhage and pain, and placental remnants are apt to remain. In the third type, after the third month, the abortion is more like a normal labor and the placenta is usually expelled completely. There is not much danger of hemorrhage unless the placenta fails to separate completely.

Ectopic Pregnancy

Death from ectopic pregnancy is due chiefly to neglect on the part of the patient, and errors in diagnosis. Approximately 60 per cent of these deaths are due to hemorrhage. Any bleeding in pregnancy, at any stage, must be considered of sufficient importance to warrant prompt investigation and diagnosis. Where a diagnosis is doubtful, sharing of the responsibility can easily be had through consultation. With the history of a missed menstrual period, moderate vaginal bleeding and abdominal pain, ectopic pregnancy must be considered. The patient should preferably be sent to a hospital for careful observation. When the diagnosis is established, prompt operation is indicated and transfusion may be necessary. The replacement of blood loss by saline, glucose, acacia, or, better, blood transfusion is not to be neglected before, during, or after the control of internal bleeding. Since 60 per cent of deaths in this condition is due to hemorrhage, it is obvious that this procedure must have been neglected. It is not usual for a patient to die at the first rupture. This fact gives us, as a rule, adequate time to prepare for operation. Fewer deaths should occur from hemorrhage in ectopic pregnancy.

Placenta Previa

Any bleeding in the third trimester of pregnancy should be considered serious until a diagnosis is made. The diagnosis should be possible

placenta previa until proven wrong. This attitude should necessitate immediate hospitalization except under unusual circumstances. No extensive examination should be made until this is done and all preliminary preparations for transfusion, bag or section are made. This diagnosis is not always easy. Usually the only symptom is painless bleeding which is frequently negligible at the onset. The presenting part is usually not engaged except in the marginal type. The rectal finger should feel a mass in front of the presenting part, and this examination usually should cause more blood loss. X-ray assistance may be had in vertex presentations by injecting silver iodide into the bladder. One may, by this means, especially in central attachment of the placenta, show the placenta between the bladder and the fetal head. This test is by no means pathognomonic and should only be used as an additional aid in the diagnosis.

The treatment of placenta previa has been more or less standardized. Williams taught that when such a diagnosis is made, the uterus should be emptied at once. At the University, Litzenberg allows time for observation and preparation of the patient, depending, of course, on the severity of the case. In central attachment, cesarean section is the procedure of choice. In partial or lateral attachment, this is also the most acceptable, especially in the primigravida. In marginal types, if the patient's condition permits, vaginal delivery may be the wisest choice where the head is engaged. Either the membranes may be ruptured or a bag inserted, and version performed later if necessary. Packing before delivery should be condemned except in rare instances. Braxton Hicks version is rarely resorted to in well trained communities. The uterus is best packed when delivery has been accomplished. In many instances the placenta must be manually removed in the presence of brisk post-partum hemorrhage. The mortality rate in the babies is high both because of blood loss and prematurity as well as from trauma. Since this is true, most of our efforts are expended in the interest of the mother. Prompt diagnosis, well planned treatment in a hospital, and blood transfusion will save many mothers in this serious condition. The prognosis is always serious. Even under good management the mortality varies between 3 and 10 per cent, and as high as 40 per cent in those poorly managed. The mortality rate can be reduced by prompt recognition of the dangers of blood loss, hospitalization and courageous treatment.

Ablatio Placentæ

Ablatio placentæ or premature separation of the normally placed placenta is the accidental hemorrhage of our fathers. This term, accidental hemorrhage, was used to designate a condition in contradistinction to that seen in placenta previa. It represents hemorrhage from a normally placed placenta, the hemorrhage being either concealed or visible. It results in the frequent death of the baby and premature labor. The concealed type, characterized by a uterus of board-like consistency, is the most dangerous and usually requires cesarean section with hysterectomy if the uterus is apoplectic. In these severe cases the uterus fails to contract and the mother may die in spite of packs, pituitrin and blood transfusions. The milder types may be treated by bag and version if labor is not already in progress. Ablatio placentæ occurs late in pregnancy or during labor. There may be a great blood loss with acute anemia and shock, especially in the concealed type. When one finds a firm board-like enlarging uterus with signs of shock, the diagnosis is simple and the treatment is section. The prognosis for the mother is grave, the death rate running from 35 to 50 per cent in the severe type. The fetal mortality runs from 80 to 95 per cent. Here again hospitalization and prompt treatment are essential. Blood transfusions are extremely important in the severe concealed types.

Postpartum Hemorrhage

Postpartum or postnatal hemorrhage usually occurs during, or immediately after, the third stage of labor. It may be divided into primary hemorrhage occurring during the first twenty-four hours, secondary from twenty-four hours to two weeks, and puerperal from two to six weeks postpartum. Hemorrhage postnatally may be considered to exist when more than 500 c.c. of blood is lost. The normal blood loss should not exceed 300 c.c. The danger does not always lie in the amount of blood loss, but the condition of the patient before the blood loss. The predisposing causes are usually listed as due to blood diseases, anemias, cardiac disease, debility, malnutrition, multiple pregnancy, repeated pregnan-

cies, atony, and certain types of women such as blonds and redheads.

The immediate and local causes are, in general, excess use of pituitrin, prolonged anesthesia or labor, atony, overdistension of the uterus, lacerations, operative delivery, improper conduct of the delivery of the placenta before its normal separation, and retained placenta.

The best treatment for postpartum hemorrhage is its prevention. Be on the lookout for it and treat it promptly. Give plenty of rest and fluid in long, fatiguing labors. Avoid the excessive use of oxytoxic drugs during labor. In operative deliveries, do not use too much haste, and avoid trauma. Do not attempt to deliver the placenta, if possible, until it is separated. Look the placenta over carefully to rule out retained portions. Use ergot and pituitrin by hypo immediately after the birth of the baby in difficult and fatiguing labors. Watch the uterus after delivery and hold it, if possible, for one hour after delivery. Have a speculum and big pack always available for packing the uterus. In patients who have had antepartum bleeding, always be prepared for postpartum hemorrhage. Hemorrhage in the presence of a well contracted uterus calls for inspection of the cervix and ligation of bleeding vessels. The essential treatment for the hemorrhage is blood transfusions, fluids, morphine, and good nursing.

Discussion

Dr. A. K. Stratte, Pine City: Dr. Swanson has covered the subject very completely, and there is very little to add. I wish to emphasize a few points he has mentioned, especially as they affect the general practitioner, namely, adequate prenatal care, conservative use of instruments and oxytoxics, and the proper diagnosis of emergencies when they arise. As he stated, there has been a marked improvement in maternal mortality rates, especially in this section; but fewer deaths should occur from obstetrical hemorrhages. During the past few years, perhaps more spectacular advancement has been made in other branches of medicine than in methods employed in the treatment of these conditions. Were all the available knowledge put into common usage, the mortality rate would be appreciably reduced. For example, in reference to placenta previa, Dr. Swanson states, "The mortality rate varies between 3 and 10 per cent and as high as 40 per cent if poorly managed."

Wherein lies this great discrepancy and where can the blame be placed? First, failure to recognize or heed the warning of third trimester bleeding, which is usually not severe at the onset. Second, failure to place the patient in a hospital under the care of a man capable of handling the case. Some general practitioners who willingly refer cases to specialists in other branches of medicine, do not call in an obstetrician even though it is clearly indicated. How else can the large variance of 3 to 40 per cent mortality rates in placenta previa be explained? The average general practitioner cannot be expected to carry the equipment, nor have the training necessary to care properly for these emergencies in the home.

The final diagnosis of bleeding in the third trimester should never be attempted in the home, because of the increased hemorrhage which usually follows examination. However, certain signs might give you a fairly accurate opinion of the cause.

In placenta previa, hemorrhage is apparent, intermittent and painless. The uterus is normal in size, shape, and consistency. On the other hand, in premature separation of a normally implanted placenta, hemorrhage, though usually apparent, may be concealed, the pain is sudden in onset, severe and continuous in nature, and the uterus is often larger than normal, hard and sensitive.

The initial hemorrhage usually being slight, morphine may be administered and removal to a hospital can usually be safely accomplished. Packing should be avoided unless the hemorrhage is excessive. Prevention of obstetrical hemorrhages begins with thorough painstaking prenatal care. Harris states that premature separation of the placenta occurs four times as frequently in toxemic patients as in those in which toxic manifestations are absent. Bleeding, no matter how slight, during any of the three trimesters should not be regarded lightly.

Postpartum hemorrhages are chiefly of two types, traumatic and atonic. If the uterus is hard, the bleeding comes from laceration, which should be searched for with the aid of a speculum, and repaired.

In the absence of trauma, the bleeding is usually atonic. Normally, bleeding is controlled by three factors: (1) contraction of the uterine muscle fibers; (2) retraction of uterine muscle fibers; (3) clotting which occurs in the vessels.

The contraction and retraction of the muscle fibers of the uterus produce a compression and kinking of the arteries, and this controls the bleeding. Conditions which prevent these normal functions are toxemias, uterine exhaustion, and adherence of the placenta to the uterine wall with a partial separation. Prophylactic treatment consists in proper prenatal care, to avoid or detect toxemias which predispose to the atonicity of the uterus. Exhaustion during labor should be avoided by rest and intravenous glucose. Avoidance of haste in expressing the placenta, conservative use of instruments and oxytocis will reduce postpartum traumatic hemorrhages. More accurate clinical diagnosis would necessitate fewer retrospective diagnoses on the death certificate.

CASE REPORT

RUPTURE OF DUODENUM IN A THREE-YEAR-OLD CHILD

O. S. WYATT, M.D.

Assistant Professor of Surgery, University of Minnesota

Minneapolis, Minnesota

BEING unable to find a report in the literature of a rupture of the duodenum in a child so young, I felt that this case warranted reporting.

This three-year-old boy was first seen by Dr. Lane Arey of Excelsior, Minnesota, about 5 p. m., May 9, 1938. The history obtained was that the lad, while climbing up the side of a large flower urn, pulled it over on top of himself, so that it struck him across the upper abdomen and lower rib margin on the right side. He ran at once to his mother complaining of pain in the "tummy." He was seen by Dr. Arey within fifteen minutes and complained only of abdominal pain. His appearance, pulse, and blood pressure were normal. He was taken home and put to bed. At 8 p. m., three hours after the accident, he was again seen by his attending physician. He was complaining of severe abdominal pain, presented a picture of severe shock, and the right half of his abdomen was rigid. His blood pressure was 112 systolic and pulse rate 140 per minute. He was taken at once to Janney Children's Hospital, and I had the privilege of seeing him about 9:30 p. m., four and one-half hours after the accident. He was very apprehensive and alert. He presented a typical shock facies, abdominal pain was severe, B.P. 100 systolic, pulse 160. Examination of the chest was negative. Examination of the abdomen revealed a mild contusion across the lower rib margin on the right side. The abdomen, moderately distended in the epigastrium, was otherwise normal in appearance.

Percussion revealed no fluid level and liver dullness was questionable.

Palpation revealed marked rigidity of the entire right abdomen, and moderate rigidity of the left. He was extremely tender in the right upper quadrant, moderately so in the right lower quadrant, and no tenderness was elicited in the left abdomen.

Flat plates were made of the abdomen but they revealed no gas beneath the diaphragm.

Our impressions were that this boy had a ruptured liver, with the possibility of a ruptured hollow viscus.

Operation.—After transfusion had been started, an upper right rectus incision was made under ether anesthesia.

Upon opening the peritoneal cavity no free blood was encountered, but a copious amount of dirty serous fluid. After aspiration of the free fluid, inspection of the liver revealed that it was normal. However, a great deal of plastic exudate was found in the region of the hepatic flexure, along the entire ascending colon, and down into the right lower quadrant. Even the appendix was covered with a plastic exudate.

Upon exploring in the region of the gallbladder, free bile was encountered and a large hematoma was noted on the anterior surface of the duodenum. There was also a large hematoma on the hepatic flexure of the colon, and in the retroperitoneal tissues. It was quite evident that the trauma was limited to this region.

Exploration of the duodenum for the possibility of a rupture revealed that bile was escaping into the peritoneal cavity. The duodenum was mobilized as much as possible and on the lateral surface of its second portion a longitudinal rent about 1.5 cm. in length was found through which bile was escaping. The mucosa was puckering through the opening. The tear was closed by whipping over Duloc sutures, and I was unable to express any more bile through it. Further examination of the duodenum revealed no more lacerations, and I could not express any bile from the lesser peritoneal cavity.

Inspection of the stomach, transverse colon, and terminal ileum revealed no other perforations. The omentum and mesentery were normal.

Soft rubber drains were placed in the region of the gallbladder and right lower quadrant. Closure of the abdominal wall was done in layers.

While the operation was going on the boy received between 350 and 400 c.c. of his father's blood. He left the table in good condition.

Naso-duodenal suction was employed on this boy for seventy-two hours, during which time he received intravenous feedings. His abdomen remained flat and at no time did he ever present any distention. On the fourth day the naso-duodenal tube was removed and feeding commenced by mouth. The convalescence was smooth with the exception of a slight wound infection, which healed by secondary intention in about eighteen days.

The patient was discharged on the twenty-fifth day. When seen three months after the accident he was in perfect health, and the mother states that she would never know that anything had ever happened to him.

Discussion.—This case is reported because of the interest it created, and likewise because the child in the case is probably the youngest on record.

Rupture of the duodenum is extremely rare following trauma to the abdomen. Rowlands reported only twenty-three cases of ruptured duodenum in 381 cases of ruptured intestines. Probably the reason that we see so few ruptures of the duodenum is because it is so well protected except where it crosses the vertebral column.

The symptoms in this case surely indicated an acute surgical abdomen, but because free gas was absent or undemonstrable in the peritoneal cavity, rupture of a hollow viscus could not definitely be diagnosed. The presence of free bile in the peritoneal cavity led us at once to suspect injury to the biliary apparatus or duodenum. We were fortunate in having a laceration which could easily be taken care of, and likewise fortunate that none were overlooked.

I consider it a privilege to be able to report this case and wish to express my sincere thanks to Dr. Lane Arey for his helpful assistance and suggestions.

HISTORY OF MEDICINE IN RAMSEY COUNTY

BY J. M. ARMSTRONG, M.D.

(Continued from October issue)

In the *Pioneer* for February 13, we note the following satirical squib:

"Dr. Charles M. Berg has slid off down the river. Berg was one of the large number of nice young men who flocked into Saint Paul last summer for office, but, like the majority, was disappointed. For several weeks past he has patronized the hotels, oyster shops, barbers, livery stables, and washwomen of Stillwater. It is said that he got into debt to about the amount of $1,000.00. Some ten days ago, the Doctor joined a trouting party to Rush river. Professing to have some business a short distance farther down the river, he left the party with somebody's horse and cutter and went down. The Doctor appears to have lost all command over the horse; for instead of returning to the fishing party next morning, a company of surveyors coming up the river reported that they met the Doctor near the foot of Lake Pepin, with his horse's head turned southward and under full speed. If the Doctor ever returns, he will probably sue the owner of the horse for the damage of running away with him."

It seems that the doctor, horse, cutter, and baggage went through an air hole in the river, but the doctor managed to extricate himself (*Pioneer,* March 13):

"The river below soon after opened and the ice commenced running. The Doctor acts like Croton oil and is bound to have a free passage through the world."

He sold his plunder at Prairie du Chien and when last heard of had reached Galena on his way to Philadelphia. Nothing further concerning Dr. Berg can be learned except that he was one of the organizers of the first Masonic lodge instituted in Saint Paul in 1849.

Both Dr. Potts and Dr. Day came to Saint Paul, as said before, in 1849, though Potts may possibly have been there previously, as he was married at Fort Snelling in 1847. In the *Pioneer,* under date of May 19, his professional card appears as follows:

Dr. T. R. Potts

Having made Saint Paul his permanent residence will attend to all calls in his profession in the town and county. He may be found at the store of Mrs. W. H. Forbes.*

Drs. Potts and Day apparently got an early hold on the community for we find them among the managers of a ball held July 4. Dr. Carli of Stillwater was also on the committee. This same year Dr. Day was appointed Register of Deeds for the newly organized county, and he recorded the first deed in Ramsey County. Dr. Potts was elected president of the Board of Trustees of the town. We may say he was Saint Paul's first mayor.

It is recorded also in the annals of Saint Paul that Dr. Day drew the plans for the first courthouse, for which he received the sum of ten dollars. This seems to be more of an exploit than the bare statement may indicate, as bids for plans

*Forbes represented the American Fur Company in Saint Paul and his store was known as the "Saint Paul Outfit." The store was on Bench Street (2nd Street) near Jackson.

were not advertised for till January 16, 1850, and had to be in the hands of the Commissioners by noon on the 20th. It is possible no others were able to compete on such short notice. Dr. Day was also one of the commission which built the court house, the construction of which was begun in 1885. His duties as Register of Deeds apparently were not strenuous. To correct the erroneous rumor that he had given up his practice, he published the following card:

"Dr. Day continues the practice of his profession at Saint Paul and will be found at his office on Third Street."

Dr. Dewey was not behind Drs. Day and Potts in social and political standing. In 1849, he was elected to represent Ramsey County in the first territorial legislature and served as a member of the executive committee of the Territorial Temperance Society, organized on October 30. At the same time that Governor Ramsey appointed Dr. Day Register of Deeds, he appointed Charles Bazille Coroner for the county. Judge Bazille, his son, stated that there were many offices to fill and few reliable men to fill them. When the appointment of coroner came up, someone remarked, "Give it to Bazille, he's the only white man left." There was some truth in the jest, as Bazille could not read or write. This same year the first dentist came to Saint Paul, though he did not become a permanent resident till 1851. His announcement under date of May 9, 1850, is curious. It reads as follows:

Dr. Jarvis

Dentist and Daguerrean

Will arrive in a few days and respectfully solicits from the citizens of Saint Paul, Stillwater, and The Falls of St. Anthony their patronage and support. He would particularly call their attention to the fact that he comes to stay and make Minnesota his home for life. His stock of materials, both in the Dentist and Daguerrean line, is most extensive and complete. Pictures taken in superior style in clear and cloudy weather.

5th Street near Jackson

This was Dr. William H. Jarvis, not only our first dentist but our first photographer. He was not the army surgeon of the same name stationed at Fort Snelling in 1836. In January, 1851, he opened a small drug store and advertised as a homeopathist; in August of the same year he opened a dental office in St. Anthony, intending to divide his time between the two places. In the spring of 1852 he closed out his daguerreotype business, and enlarged his drug store with capital furnished by Dr. J. H. Day, calling it "The Multum in Parvo Drug Store." After a number of years he gave up the drug business and opened a nursery on the west side of the river, raising vegetables and small fruit. He died in Saint Paul in the eighties. He is said to have been an Englishman and was born about 1828.

During the year 1849 a man whose name is still well known to the local medical profession located at St. Anthony and began the practice of medicine there. He received his diploma from Rush Medical College in 1850, and moved to Saint Paul in 1863. He is included here at this time because St. Anthony was then part of Ramsey County and his later activities were in Saint Paul. His name was John Henry Murphy.

John Henry Murphy was born January 2, 1826, at New Brunswick, N. J. He received part of his education at Quincy, Illinois, and boarded for a time with the parents of William W. Sweney while he and young Sweney studied medicine together under Dr. Abraham B. Hull of Marietta, Illinois. Following the custom of the day he established his practice before receiving his diploma, settling at St. Anthony. In 1850, he returned to Rush Medical College and completed his course. He practiced medicine at St. Anthony for ten years until the Civil War broke out

and he went into the army. His family then moved to Saint Paul, and to the latter city he returned upon his discharge in 1863, to continue his practice until his death January 31, 1894. He was a member of the state constitutional convention and of the state legislature, and served for many years as Surgeon General of the state. He was also at one time president of the Association of Railway Surgeons, president of the Board of Pension Surgeons, and a member of the Saint Paul school board.

He was a large, uncouth man, uneducated, and possessed of a rather broad sense of humor. He had the reputation of being a great surgeon, and he firmly believed it himself. Although he did curious and bizarre things in surgery, his patients never seemed to hold it against him. He would do anything in a rough and ready way except eye surgery, and he firmly believed that all surgical patients in the community belonged to him by right, particularly fracture cases. It mattered not to him who their physician might be, or whether or not he was sent for. In many cases the ethics of practice as generally understood seemed to be absolutely incomprehensible to him. When a fellow doctor complained to him of a breach of etiquette such as stealing a surgical patient, he would make apologies, only to do the same thing again the next day, naively unaware that he had done anything wrong. In many ways he was a most lovable man, greatly liked and widely known. Probably there have been more curious stories told about Dr. Murphy than about any physician who ever lived in Saint Paul. Many young men, notably Edson Wait, James J. Dewey, Henry F. Hoyt, Ed. Whitcomb, James A. Quinn, and Clinton C. Miller, studied in his office. For many years in the early days he was the only physician in Minnesota who belonged to the American Medical Association. He served at different times as surgeon in the First, Fourth, and Eighth Minnesota Regiments and also was Division Surgeon. He was president of the Ramsey County Medical Society in 1874. At the time of his death he had perhaps a wider acquaintance than any man in the city.

Another physician came to Saint Paul with Governor Ramsey in 1849, Dr. Thomas Foster. He had practiced medicine in Pennsylvania but probably did not practice in Saint Paul. He came there as secretary to the governor, being at that time thirty-one years of age. In 1852 he was appointed physician to the Sioux Indians and later engaged in the drug business. As part owner and editor of the *Daily Minnesotian,* during the years 1857-61, he was one of the early newspaper men in the state. He served in the Civil War, attaining the rank of captain in the commissary department. In 1869 he established the Duluth *Minnesotian,* the first newspaper to be published in that city. He was born in Philadelphia, May 18, 1818, and died in San Francisco, March 31, 1903. He is said to have coined the phrase "The Zenith City of the Unsalted Seas" as descriptive of Duluth.

During this year cholera made its first appearance in Saint Paul. One of those who died was L. B. Larpenteur, the grandfather of the late A. L. Larpenteur. He was buried at the head of Jackson Street, about where the city market is now. Later his remains were removed first to a cemetery situated at the present location of St. Josph's Academy, and still later from there to Calvary Cemetery.

The year 1850 found a surgeon-dentist, Dr. A. G. Stiphers, announcing his skill in making artificial dentures:

> "Scurvy and all other diseases of the gums, mouth and teeth cured, charges moderate, all work warranted."

Just how frequent scurvy was at that time is not known; but presumably it was not infrequent, as fresh vegetables were difficult to secure in the winter, and it was thought Minnesota was too cold for the raising of potatoes. Furs,

cranberries, and pine lumber were the only products exported from the territory. In contrast to the difficulty of securing fresh provisions, whisky was cheap enough, twenty-five cents a gallon "and a better quality for twenty-eight cents." During this year also, Drs. Lee and Reynolds, both dentists of Dubuque, announced that one of them would spend a few weeks in Saint Paul and do dental work. A Dr. Todd who appears as a resident of Saint Paul and a member of a river excursion on July fourth was probably a clergyman, not a doctor of medicine. Although the town was but one year old, political squabbles and animosities were already rife, as is instanced by this note on the editorial page of the *Pioneer* for March 6:

"It is gratifying to learn that T. R. Potts, M.D., late of Galena, has been promoted to the office of Sioux doctor and Chief Surgeon to his Majesty Little Crow. It is a sphere for which he is better adapted than any other he has heretofore occupied."

What it was that excited this sarcastic tribute from the acid pen of James M. Goodhue, the paper does not state. Dr. Potts held this appointment till late in 1850, when Dr. Williamson was reappointed. Dr. David Day became the examining physician for the National Loan Fund Life Assurance Society of London and New York, the first life insurance company to establish an agency in Saint Paul. Late in December Dr. C. Rich opened an office in the building formerly occupied by Dr. Barbour's store on Third and Minnesota Streets. By 1850 Barbour had moved to another town, having sold his store to Wm. W. Hichcox. Sometime during the year Dr. William Wilson Sweney came to Saint Paul. He had been studying medicine under a preceptor for three years but had not as yet received a diploma. Dr. Sweney's activities are recorded in the section of this book relating to the medical history of Red Wing.

It may be of interest to insert here the deaths occurring in the "District of the County of Ramsey, Minnesota Territory," for the year ending June 1, 1850, as they appear in the census of 1850.*

Name	*Age*	*Place of Birth*	*Days Ill*	*Cause of Death*
Pierre Gervais	8	Minn. Territory	42	unknown
Magdeline Donna	60	Canada	15	fever

Francis Robert	25	Missouri	90	consumption
James Goodhue, Jr.	2	Wisconsin	20	teething

In the manuscript division of the Minnesota Historical Society may be found the early account books of Dr. Potts. The first entry is dated May 20, 1849, the day after he arrived in Saint Paul. It seems worth while to give here some of the entries in his books. It should be noted that in all instances he gives the

*It is probable that the deaths from cholera occurred in the summer of 1849 rather than in 1850, at least John Lumley (not Lurmley) who worked for Larpenteur died in 1849. Barber should be spelled Barbour in the above.

names of his patients and the fee charged, but no case histories. His books are a veritable directory of Saint Paul at that time.

1849 June 11—Blister .50
July 24—E. Rice—to obstet. 20.00
Sept. 8—Visit to the Falls 9.00
Sept. 27—Visit to Ft. Snelling 7.00
Dec. 5—Visit & Med. 80.00 Sauk Rapids

1850 Jan. 29—Obstet & detention 35.00
Feb. 28—to advice & med syphilis 25.00
March 14—to visit and scarifying gums 1.00
May 20—visit and consultation Dr. Day 5.00
May 24—visit at night 2.00
May 30—v. & opening abscess 3.00
June 10—to visit & med (Falls) Smallpox 10.00
July 20—obstet 10.00
Aug. 6—obstet 5.00
Aug. 6—extracting mote from eye 1.00
Sept. 29—visit and Mendota 6.00
Oct. 12—dressing wound 2.00
Oct. 25—visit and blister 1.25
Nov. 3—visit and consultation (Falls) 10.00
Nov. 8—reducing luxation 10.00

1851 Jan. 15—J. M. Goodhue—to dressing wound 10.00
April 25—D. A. Robertson—to visit and chloroform 1.00
May 28—J. R. Brown—to extracting bone from throat 1.00
Nov. 15—setting fracture 5.00

1852 Jan. 23—visit and cupping 1.00
May 23—visit & setting arm 10.00
July 25—E. Rice—consultation Dr. Day 5.00
Oct. 29—Setting fracture 10.00

1853 Feb. 27—reducing hernia 5.00
May 31—reducing fracture 10.00
Sept 5—C. W. Borup—reducing fracture 20.00
Oct. 28—reducing dislocation 5.00

1854 Jan. 4—Post Mortem of Philip Hull 20.00 (chg. County)
June 26—to operation of trephining 10.00
July 1—to consultation Dr. Day 5.00
15.00
Aug. 10—D. C. Dustin—to att'd & detent on self (cholera) 10.00

1855 Jan. 25—Consultation Dr. Goodrich 5.00
March 15—Consultation Dr. Morton 5.00
March 26—Consultation Dr. Wren 5.00
April 3—tapping hydrocele 5.00
April 4—to Morrison (Hospital) with Dr. Marsh 1.00
May 16—Consultation Dr. Marsh 5.00
July 12—Haskin (Winslow House) consultation Dr. Stewart 5.00
Nov. 17—Seager
To att. on wife 20.00
By cash 10.00
By copy of Shakespear 10.00
Nov. 20—Introducing catheter 5.00

His ordinary fee for a visit was $1.00. Sometimes a small amount, as 28 cents, was added for medicine; night visits were $2.00. The word "detention" means that he was detained for a long time. In the case of Dustin he spent the entire day with his patient. Mileage was charged for visits to St. Anthony, Fort Snelling, Mendota, and Sauk Rapids. This last visit evidently occupied three or four days

as there are no entries on his books for one day before and two days after. It is interesting also to note that he never received his fee for this trip. The mention of chloroform in 1851 is rather early for this part of the country. The total of his charges for the year 1850 amounted to $1,224.53. He received during that period $69.80 in cash, a cupboard, one load of wood, and one dozen chickens. He seems to have made no particular effort to collect his accounts during the years 1849 and 1850, and his ledger was made up in 1851, probably by his wife. It is interesting to attempt to compare his book charges with those of today. The overhead charges in practicing medicine today are from 37 to 40 per cent, while his at that time could have been but a fraction of that. If one knew what percentage of his accounts he was able to collect and what was then the cost of living, one could arrive at a figure indicating the financial status of a physician in Saint Paul at that time. From the names on his books, only a few of which have been given, it appears that he had the best practice of any Saint Paul doctor during those years. During the months of June and July, 1850, are many charges for vaccination at one dollar each. It is also noted that on March 5, 1855, the writer's grandfather paid him $53.00 for attendance on his wife, who suffered from an attack of typhoid fever in the autumn of 1854.

1851

In April Dr. Barbour returned to Saint Paul and began again to solicit "a share of public patronage," announcing "he will practice upon the Eclectic Reform Principle, discarding mercury in all its forms." The name of the coroner for this year is not known, but a notice of an inquest to be held May 22 was signed Orlando Simons, Acting Coroner. Simons was not a physician. On May 29 Dr. Sweney returned to Saint Paul, after receiving his diploma from Rush Medical College. He opened his office on St. Anthony Street (West Kellogg Boulevard) next door below Mr. J. Irvine's (between Washington and Franklin Streets). Lee and Reynolds, the traveling dentists, again visited Saint Paul, and Dr. I. B. Branch, a Galena dentist, made a trip up the river and advertised he would be at the American House (N. E. corner Kellogg Boulevard and Exchange Streets) for a few days. Some time during the latter part of the autumn, Dr. Charles Rich moved from Saint Paul to Dubuque. He was evidently employed at some time during his stay in Saint Paul as county physician, for on one occasion he collected a bill from a patient, and also received $5.90 from the county for the same case.

The *Pioneer* of September 4 makes the following comment regarding him:

"Dr. C. Rich and family left by the Nominee last week, being in debt to many people in St. Paul and especially to the printer. This reminds us of the old maxim 'Riches take to themselves wings and fly away' and we cannot help heartily and meekly responding 'Give us, Oh Lord, neither Poverty nor Riches.'"

The rapid growth of Saint Paul and the neighboring country is evidenced by the arrival of six more physicians later in the year. These men were Dr. James D. Goodrich (Sept. 25), Dr. John Harvey Day (Oct. 9), Dr. Albert G. Brisbine (Oct. 16), Dr. O. E. French (Oct.), Dr. R. Babbitt and Dr. Carlios (Nov.). Dr. Goodrich opened an office in the "Democrat Building, Wabashaw and Third Streets"; Dr. Day, "Office on Bench Street" (now 2nd Street); and Dr. Babbitt "in the rear of Levi Sloan's Store" (Kellogg Boulevard between Franklin and and Washington Sts.). Goodrich, Brisbine, Day, and Babbitt had simple cards in the paper announcing their arrival and where they might be found. Dr. French's announcement, however, is worth giving in full, as is also that inserted by Dr. Carlios. They are as follows:

O. E. French, M.D.
Surgeon and Physician

Graduate of Harvard University, Cambridge, Mass. Dr. F. believes it is a duty, as a stranger, he owes himself and the community, as he intends to make Saint Paul his permanent residence, to state that he has had many years' experience in the hospitals and practice of the Eastern Cities, and also of the diseases of the Mississippi Valley,—is a graduate of the oldest and first University of the country, and was for a number of years the private pupil of the most eminent surgeons and physicians of New York, Boston and Philadelphia. Dr. French will give particular attention to diseases of women and children, and respectfully offers his services in the practice of Surgery, Medicine, and Midwifery to the citizens of Saint Paul and vicinity.

References

Drs. Crow, Ray, Robertson, Kittoe, etc., Galena; Messrs. Hollingshead, Rice, and Becker, Mr. Roberts, J. W. Simpson, S. H. Sargent, Gen. McBoal, St. Paul.

Dr. Carlios
Surgeon, Physician, and Accoucheur

A graduate of the Paris and Turin Universities has taken his residence in Saint Paul. He will take pleasure in exhibiting his diploma to anyone who desires to see it. Dr. C. will have his office at Mr. Turpin's on Fourth Street, Saint Paul; where he can be found and will promptly attend to every call.

N. B.—Dr. C. has instruments of the most approved kind for every surgical operation ever required.

It is interesting to compare these announcements with the modest professional cards of Goodrich, Babbitt, Brisbine, and Day. The claim of Dr. French that he was a Harvard graduate is verified by the catalogue of that university. He led a rather peripatetic existence, as shown by the attached biography. As to Carlios, Paris and Turin Universities are too far away to make the search for his name. In October, at the county election, P. T. Reid, a merchant, was elected coroner over W. Chapman, receiving 288 out of 534 votes.

One of the principal events of the year 1851 was the encounter between James M. Goodhue and Joseph Cooper, which occurred on January 15. Both men were wounded. The latter lived for a short time; the former died on August 27, 1852. Although his political friends asserted that his death was occasioned by the wounds he received, his survival for a year and a half makes such a statement ridiculous. Dr. Potts, who attended Goodhue, has left us the following statement of the case:

"You will see by the papers an account of a fight between Goodhue and young Cooper. The *Chronicle* today gives a long one sided account of the affair, and as old Jim is on his back and unable to write an account of the affray himself, some of his friends intend writing a short description of the affair and support it by a few affidavits. He shot Cooper above the bone of the pelvis and Cooper stabbed him in two places, one far back on the left side and the other about a half inch from the navel. Both wounds bled a great deal and gave people the impression that he was mortally wounded, and indeed he was under that conviction himself even after I had told him that neither of the wounds had penetrated any of the cavities. The morning after the affray he took a small dose of oil, and anxiously waited for the operation of it to find out whether the communication had been cut off. After it had operated he said, 'he was satisfied now that there was a communication between both ends yet' . . ."

(Dr. Potts to H. H. Sibley, then in Washington, Jan. 21, 1851.)

Reference may here be made to another misstatement concerning Goodhue. It is said in most accounts of him that he was buried somewhere on Dayton's Bluff. Actually, he was buried in Oak Hill Cemetery, which was organized the year of his death, and was situated between the present Mackubin and Western Avenues, on the west and east, and between Front and Maryland Streets on the north and south. This cemetery was soon abandoned and his remains were transferred in 1857 to Oakland Cemetery.

1852

There were now eleven physicians in Saint Paul. Dr. Sweney in January had associated with him a Dr. Abraham Hull, and the two men opened an office on St. Anthony Street over Sloan and Farrington's store (between Franklin and Washington). They advertised their services and also "an assortment of pure medicines for sale." Dr. Goodrich moved his office to the Saint Paul Drug Store (3rd and Cedar). Dr. Potts' announcement remained the same as it was in 1849. Either he was satisfied with Forbes' store for an office or he was careless in not changing his card in the paper. In the *Pioneer* under date of March 19 appears the following item:

"Hospital—In the rear of the American House, Mr. Rey, firm of Rey and Farmer, and Dr. Carlios, an eminent Medical and Surgical Practitioner from Paris, are laying the foundation of an extensive Hospital, upon ground given for the purpose by H. M. Rice, Esq."

This was the first promise of a hospital, but the plan seems not to have been executed. The records of the Abstract Office do not show that the land in question was ever transferred to the aforesaid gentlemen, and it is unlikely that the hospital was ever built, although Carlios rented Vital Guerin's house for his patients pending the completion of it. In May Drs. Hull and Sweney withdrew their card from the paper; presumably Hull left town. He may have been Dr. Abraham B. Hull, of Marietta, Ill., who was the preceptor of both Dr. Sweney and Dr. J. H. Murphy. There was no divorce law in Minnesota at this time. The legislature passed a bill granting A. Hull a divorce from his wife, Julia A. Hull. Governor Ramsey vetoed the bill on February 2, 1852. Presumably this was Dr. Hull. Late in the year Dr. Sweney went to Red Wing, where he remained till his death, August 12, 1882. In July Dr. Charles Ludwig Vicchers came to Saint Paul and opened an office on the corner of Fourth and Robert Streets, over Cathcart's and Tyson's store. In June Dr. French's advertisement was withdrawn. In May there were unclaimed letters in the post office for Dr. Hendee and Dr. Wm. Lewis. Probably they were connected with Owen's Geological Survey; at least there were unclaimed letters at Fort Snelling in 1849 for Dr. Lewis and Dr. B. E. Shumard, both of whom were connected with the survey. Shumard became a professor of obstetrics in a medical school in St. Louis, and in later years attained fame both as a geologist and as a physician.

Another dentist, G. W. Biddle, of Pittsburgh, located in Saint Paul in May, and Mrs. Biddle announced she would give instruction on the pianoforte. They established themselves at Hill and St. Anthony Streets. Biddle later bought some land above the present Seven Corners that had been preëmpted before the land was released by the government. Complications arose when someone staked out a claim on the property. This same predicament occurred to others; and they therefore organized for mutual protection to keep newcomers off. The organization was known as the Fort Snelling Claim Association. Biddle later located in Springfield, Illinois, and numbered among his patients Abraham Lincoln and his family. After several changes of residence and occupation he settled in Sparta, Illinois, where he was living in 1904, aged seventy-five years. In August, 1852, Dr. McLaren of Fort Snelling was ordered to Jefferson Barracks at St. Louis, and Dr. Ames, "a physician of excellent repute" of "All Saints" (Minneapolis), took his place as contract surgeon. In August, also, the Common Council of Saint Paul appointed a committee "for the purpose of investigating the facts connected with the appearance and progress of the smallpox in our city." The committee called in Drs. J. H. Day and Carlios, and made a canvass of all cases. They reported that the disease had made its appearance about two months previously, but that it was mild in form, and was not to be considered epidemic. There had been no new

cases, they said, for two weeks. Of the twelve cases, eleven were now convalescing satisfactorily; one death was recorded, of "an infant previously afflicted with the measles." The Committee recommended care in the reporting of cases and stated that "a suitable place has been secured by the Board for the reception of patients." This place is said to have been a house at some place toward Fort Snelling from the present Seven Corners, but definite facts are not now available.

In August, or early September, Dr. Thomas Theodore Mann arrived from La Pointe, Wisconsin. He travelled by canoe through the Brule and St. Croix rivers to Stillwater, the immemorial route of the Indians from the Great Lakes to the Mississippi. An elaborate announcement of his intention to practice in Saint Paul appeared in the *Pioneer* for October 7, 1852:

Dr. Mann

Of Philadelphia offers his services, professionally to the citizens of Saint Paul. Residence at Mrs. Ford's, Fort Street, near the residence of the governor. Being a stranger in Saint Paul, Dr. M. bespeaks a share of their confidence, by presenting the following cards from men of eminence and distinction, furnished some years since in reference to a surgeoncy in the U. S. Army.

* * *

From Governor Shunk:

Hon. W. L. Marcy—Sir: Permit me to join his other friends in commending to your consideration the application of Dr. T. T. Mann for appointment of Surgeon. Dr. Mann's private worth and professional skill are amply sustained and show that his appointment will be a just recognition of his merits.

Yours very respectfully

Harrisburg, Nov. 23, 1846 (Signed) F. R. Shunk

* * *

From Col. James Page, Col. W. E. Patterson and others:

To the Hon. W. L. Marcy, Secretary of War: Dear Sir: We the undersigned being fully convinced that the professional standing of Dr. T. T. Mann, richly qualifies him for the commission of a Surgeoncy to one of the volunteer regiments, raised under Act of Congress passed at the last session, do most cordially unite in recommending him to your favorable notice as a gentleman of skill and experience, and who we believe would make an efficient medical officer. We shall be most happy to hear of his appointment.

(Signed) James Page — Richard Vaux — H. S. Patterson, M.D.
W. E. Patterson — Geo. McClellan, M.D. — Washington Atlee, M.D.
W. R. Grant, M.D.

* * *

From Prof. Geo. McClellan, the most distinguished of American Surgeons:

From a long personal acquaintance I feel great pleasure in uniting with the above gentlemen in recommending Dr. Mann to the Commission he solicits.

(Signed) Geo. McClellan, M.D.

This announcement appeared again one week later (October 14). Anyone familiar with the history of Philadelphia will recognize the names of these men as very prominent either socially or professionally. Richard Vaux, known as "Dickie" Vaux, is said to have been the only American civilian who ever danced with Queen Victoria. In the late autumn Dr. Carlios' notice disappeared from the paper. In the same month Dr. Samuel Willey arrived in Saint Paul and almost immediately went into partnership with Dr. Brisbine; both were from Ohio. Their office was on St. Anthony Street, three doors below the American House.

Two physicians were married in Saint Paul during the year. Dr. Pugsley of Wisconsin, perhaps the first physician to be married in Saint Paul, took as his bride Miss Emeline Brewster. The service was held on June 10, 1852. On November 10 the Rev. Timothy Wilcoxson united in marriage Dr. C. L. Vicchers, a German physician, and Miss Anna Coulter.

The Significance of the Apical Systolic Murmur

A SYSTOLIC murmur heard at the heart apex is not an uncommon finding in routine examination. Few physicians find them as frequently as Reid and Fahr, who have reported an incidence of 20 and 35 per cent in normal youthful patients.

At the turn of the century and even as late as the onset of the World War this finding was generally considered indicative of valvular heart disease and a student was frequently prohibited from strenuous athletics or a recruit was refused enlistment on this account alone.

Mackenzie was among the first to emphasize the importance of the functional capacity of the heart rather than the presence of murmurs and expressed the opinion that the presence of a systolic apical murmur in a normally functioning heart without enlargement or arrhythmia did not indicate organic valvular disease.

Cabot called attention to the rarity of uncomplicated mitral regurgitation in routine autopsies and does not believe that pure mitral insufficiency can be diagnosed during life. Personally we question the possibility of absolutely ruling out the presence of a slight leak in the mitral valve by autopsy examination.

Gradually the profession has come to accept Mackenzie's view of the significance of the apical systolic murmur. However, other factors than just the heart findings should be taken into consideration in evaluating a given case.

An analysis by Finberg and Steuer* of 100 youthful patients presenting a systolic apical murmur and observed over a period of years, is of interest. These were normal individuals except for the presence of the systolic murmur and except that 30 per cent of them showed a heart shadow over 50 per cent of the chest diameter on orthodiagraphic examination. Without going into details of the analysis, they concluded that the presence of the murmur in children under five years of age is not significant; that in youngsters with a systolic murmur and a history of rheumatic fever or chorea there is a 50 per cent chance of the development of mitral stenosis, aortic regurgitation or both; that in the 30 per cent showing heart enlargement some 40 per cent developed later serious valvular trouble; that a slight elevation of temperature (99 to 100) occurred in 70 per cent of the cases and proved of no prognostic value as to the later development of serious heart disease; that mitral stenosis or aortic regurgitation appeared on the average three or four years after first observation; and that in only eight instances did the murmur disappear. Recently the same authors† reported the observation for over ten years of thirty-five of the original 100 patients without the discovery

*Finberg, M. H., and Steuer, L. G.: Apical Systolic Murmurs in Children. Am. Heart Jour., 7:553, (June) 1932.

†Steuer, L. G., and Finberg, M. H.: Further Observations on Apical Systolic Murmurs in Children. Am. Heart Jour., 16:351, (Sept.) 1938.

of any new cases of mitral stenosis or aortic regurgitation.

The development of twenty-nine cases of mitral stenosis or aortic regurgitation or both in these 100 observed patients proves definitely that the group was not a normal one to begin with. Disregarding the twelve of the thirty patients with fluoroscopic evidence of heart enlargement who eventually developed mitral stenosis or aortic regurgitation or both, the number (17 per cent) that developed severe heart disease is still much too high for a normal group.

The conclusions drawn by the authors from this study are that as a group children with systolic apical murmurs are more likely to develop serious valvular disease. The statistical source of these authors might explain the apparent importance of a physical finding not commonly regarded as significant.

Biographic Data

PERUSAL of the files of most county medical societies would disclose a dearth of recorded information regarding present and past members. Attention is called to the situation in an article by Dr. Monte C. Piper entitled Authentic Biographical Data, which appears in this issue. Dr. Piper is the author of a new application for membership form which has been adopted by the Council of the State Association for use by all new members. This form is much more complete than the forms usually used by county societies, and its adoption gives uniformity to the information tabulated in all counties in the state. The form is made out in duplicate, one copy being filed by the local county and the other by the state office. Some counties have sent this form out to all county society members with the request that they be filled out for record purposes. Strange to say, many have neglected and some have even declined to fill out and return the forms. This is a thoughtless attitude when one considers the good reasons for the request.

We think Dr. Piper's suggestion that supplementary blanks be filled out periodically, is a good one. There is little space in the new application forms for information regarding a member's activities since graduation. If every five years a supplementary form were filled out giving information such as teaching positions, articles published, society and staff membership, postgraduate studies, specialization, additions to the family, children studying or practicing medicine, there would be on file a gold mine of authentic information which would be available for various purposes.

One of the minor uses of such a file would be its use in the preparation of life sketches for publication on the death of a member. Too often the information available is a newspaper clipping or very scanty information supplied by a relative.

How scant is the available information about most of the pioneers. Such a store of reliable information would be of inestimable value to future medical historians.

One does not have to have any particular flare for medical history in order to derive considerable pleasure from looking over what meager biographical information is to be found in the files of the county societies.

It is to be hoped that a systematic effort is going to be made to obtain these supplementary reports and that members will coöperate by filling out the blanks already sent them, and any that may be sent them in the future.

The Saint Paul Profession and City Council

THE City of Saint Paul acts as its own insurance company in complying with the provisions of the Workman's Compensation Law regarding injuries sustained by its employes. On the grounds that certain members of the Ramsey County Society have rendered excessive bills for professional services to injured employes a threat was made a year ago by the Corporation Counsel to appoint one surgeon on a salary basis to care for all injured city employes. As a result, a committee of the Ramsey County Medical Society has been conferring with city authorities for several months in an effort to promote fair dealing and coöperation between the local profession and the city authorities. The committee offered to investigate any medical bills considered by the city to be excessive and attempt unofficially to adjust fees to the satisfaction of surgeons and city officials alike. Several bills were subsequently referred to the doctors' committee and the reductions recommended in certain cases after conference with the surgeons were as a rule agreed to.

Matters were apparently proceeding smoothly until October 4, when out of a clear sky the Council of the City of Saint Paul voted to appoint five Saint Paul surgeons to care for city accident cases on a fee basis—against the known wishes of the Saint Paul profession and also against the wishes of the city employes. Both these bodies wanted to maintain the free choice of surgeon for the individual employe.

At a special meeting of the Ramsey County Medical Society held October 12 to consider the action of the City Council a resolution was passed calling attention to the fact that this action of the City Council attempted to deprive 99 per cent of the physicians and surgeons in Saint Paul from rendering services to their patients who are city employes; that this action is not in accord with laws of the State of Minnesota, whereby an employe "should have the option or unquestioned right to choose his medical attendant or accept the one tendered him by the employer—" or as the State Supreme Court has held "the statute contains no language unconditionally requiring the latter (employe) to accept the physician tendered him or relinquish the right of reimbursement altogether. . . . The fact that the employer in this case is a municipal corporation and employs a physician for all such cases, paying him a fixed salary, cannot alter the construction given the statute." The resolution further calls attention to the fact that the Central Council of Public Service Employes has gone on record as being almost unanimously opposed to the action taken by the Council; that the members of the Ramsey County Medical Society are taxpayers and in addition furnish at no expense to the taxpayers the entire medical staff of the Ancker Hospital and the resolution declares the society opposed to such an un-American and undemocratic action that aims at the destruction of the principle of free choice of physician. It was further resolved that no member accept the appointment by the city; that the individual society members pledge themselves to continue to render services to city employes and use the services of the proper tribunals to collect fees if necessary; and that the society continue to coöperate with the city to eliminate abuses on the part of members and others in furnishing medical and surgical attention on the basis of free choice of physician by the employe.

Five surgeons were appointed by the Corporation Counsel and printed cards were distributed to employes with the names of the surgeons and instructions to patronize only the surgeons named if the employe expected his medical fees to be paid. Some, perhaps all, of the surgeons have declined the appointment and there the matter rests at the present time.

Charts prepared by the Children's Bureau at Washington showing the infant mortality in the various states for 1936, show Connecticut heading the list with 42 per 1,000 live births and Minnesota, Oregon, Nebraska and New Jersey tied for second place with 44. The rates are as a whole lower for the northern states, and Arizona, New Mexico and South Carolina had the highest mortality, 120, 122 and 81 respectively.

MEDICAL ECONOMICS

LETTERS FROM NEEDY PATIENTS

SOME of the most illuminating and valuable information secured in the course of the Minnesota State Medical Association's Survey on Need and Supply of Medical Care has reached the State Office as a result of a newspaper appeal for information to all Minnesota newspapers, September 21.

This appeal was approved at the special meeting of county officers and delegates held in Saint Paul September 10 and released to all Minnesota newspapers September 21.

To date 200 responses have reached the State Association and each mail brings additions.

Text of News Appeal

Following is the text of the appeal:

Have you ever been deprived of a doctor's care when you needed it? What was the reason?

The Minnesota State Medical Association is now engaged in a state-wide study of medical needs in Minnesota and, in a statement issued today, asked the cooperation of patients themselves in an effort to make the study useful and complete.

Anyone who has any complaint to make or who has had any difficulty in securing medical care is asked to take part in the study by answering the above questions in a letter addressed direct to the Minnesota State Medical Association.

Communications will be kept confidential if the writer wishes and the Association will investigate the complaint and give whatever assistance is possible to the writers.

In addition, the data thus gathered will be used to round out the most complete study ever made of this much discussed problem. Upon findings, the doctors plan, according to the statement, to base recommendations for changes and improvements wherever they may seem to be needed, to the end that nobody in Minnesota may be deprived of good medical care.

Replies should be sent to the Minnesota State Medical Association, Saint Paul.

Between Restrictions

It was to be expected, of course, that a certain number of these letters would come from the chronic complainers and those who embrace all opportunities to describe their symptoms.

The great majority, however, give concrete instances of a condition suspected for some time by physicians but never before so impressively backed up by names, dates and details.

This is the condition: While people on the direct relief rolls are provided with the medical service they need — letters are conspicuously missing from recipients of direct relief—the people who are on WPA and those who are on the Old Age Assistance rolls are much too often caught between the restrictions.

In the case of Old Age Assistance, a definite provision is made in the regulations for budgeting an allowance for medical service for illnesses of a chronic or recurring nature. For emergencies the regulations definitely assign responsibility to the County Welfare Board. These regulations are clearly not recognized in a considerable number of Minnesota counties, nor are they understood by the recipients of aid.

Provided in the Law

There is, of course, no reason why these elderly people should lack medical aid in Minnesota. The law was carefully written to provide for it and the regulations adopted by the State Board of Control are explicit on the subject. It is clear, however, that missionary work is needed with county commissioners and other members of the welfare boards in a number of counties to show them their responsibility and explain to them the regulations.

The problem of medical care for WPA workers may be more difficult to solve under present regulations, but a determined effort on the part of doctors and local officials in each community should serve to create a definite understanding and a plan by which medical care can be supplied universally to these workers.

For Glasses, Dental Care

Need for glasses and dental care bulks very large in all these complaints. It is clearly very difficult for many County Welfare Boards to find funds for such non-emergent needs as these. This is a special problem for physicians, dentists, welfare boards and representatives of optical houses to work out together in each community.

In addition to the letters from those who are already recipients to some degree of some form of aid, there is a residum of letters from people who are not on the public rolls; who fear to run up doctors' bills and who are actually in serious need of medical attention. In several cases these people warmly praise their doctors, acknowledge readily that the doctor would give them the service they need if they were to apply to him regardless of their ability to pay. Nevertheless, they cannot bring themselves to ask more of that already overburdened friend.

These letters are in the minority, of course, but they should have the careful consideration of medical society representatives who investigate all these cases.

Procedure

The procedure to be followed in this investigation was outlined definitely at the special Council meeting held in Minneapolis, October 15.

Copies of the letters from each councilor district will be sent to the respective councilors and by the councilor to the officers or contact committees of the county or district society concerned.

These officers will be asked to investigate and report on each case to the councilor. Wherever advice as to official procedure would help, then the local physician will be asked to find a way to give that advice and assist the writer of the letter.

The importance of careful, sympathetic, well-considered action on each case cannot be overestimated.

Reputation at Stake

The request for information was officially ordered at the special meeting of county officers and delegates in Saint Paul, September 10. As a result, many honest appeals for aid have been made. They must be carefully and honestly answered. The reputation and honor of the Minnesota State Medical Association and its members is at stake.

GROUP HOSPITALIZATION IN MINNESOTA

Group Hospital insurance was approved in principle at the special House of Delegates meeting in Chicago. It is, of course, already established and working successfully in a good many cities, notably in Minneapolis, St. Paul and Duluth.

Requests for extension of the service have been received by the Minnesota Hospital Service Association from a number of Minnesota communities.

The question of whether or not group hospitalization can be organized and operated with equal success in the rural districts was discussed at length at a joint meeting of the Council, the Council Committee to Study Group Hospitalization and a committee from the Minnesota Hospital Service Association in Minneapolis, October 15.

No definite action was taken by the assembled group, but the hospital service representatives indicated that they will make a further study of plans for extension into rural communities and report the results to the joint committees.

Any plan of organization that may be agreed upon will be submitted to the local county or district medical society concerned before action is taken.

REACHING THE STUDENTS

The Minnesota State Medical Association will continue the college lecture courses carried on in former years under the joint auspices of the medical association and the Minnesota Public Health Association.

The importance of reaching the college group prompted arrangement of the new courses by which, at the direction of the Council, two lectures will be offered to each college each year.

A carefully selected list of subjects has been prepared under the direction of the Committee on Public Health Education and four speakers have been chosen to present each subject. College authorities will thus have the opportunity of a wide range of subjects and speakers from which to make selections.

Reaching college students who will become the teachers, professional men and leaders of the next generation, is one of the most important parts of the health education program. Lectures to students are regarded by the Council as essential to this program.

SECOND CONGRESS

Dates for the 86th Annual Meeting of the Minnesota State Medical Association are May 31, June 1 and 2.

The place is the Minneapolis Auditorium and preliminary plans outlined by the Committee on Scientific Assembly provide for a program of unique proportions.

In addition to the usual fine scientific program there will be a Second Congress of Allied Professions occupying a full day of program time. All of the allied professions including dentistry, nursing, pharmacy, social welfare, hospital administration, will participate in this program which takes on a vital importance this year, in view of new programs now under discussion for medical care.

Specific Objective

The First Congress, held in Saint Paul three years ago, provided opportunity for expression of varying points of view toward the general problems of medical care. The 1939 Congress will have a more specific objective.

The theme of the meeting as outlined at a recent gathering of the Committee on Scientific Assembly is as follows: What has Minnesota accomplished to date in each of the fields of public health and medicine? Where does each program need improvement and what form should that improvement take?

Whatever enabling legislation Congress may pass at Washington this winter, the extent and character of the program in Minnesota will depend upon the legislative and health authorities in Minnesota. Official policies are certain to be greatly influenced by the discussions at this Congress.

Health Show

A second unique feature of the Minneapolis meeting will be an extensive health show. This show will occupy the entire basement of the Auditorium and will be open to the public for the entire three days of the meeting. During the daytime, groups of children from the Minneapolis schools will be escorted through the show by arrangement with the hygiene department of the schools and Minneapolis Board of Health.

The assistance of all of the health and welfare agencies in the state is being solicited to make the show complete.

STATISTICS OR SOUND JUDGMENT

(Monthly Editorial Prepared by the Medical Advisory Committee)

Happy is the medical man who never has trouble of any kind, who is always sure of his ground, who never makes a mistake in diagnosis, and whose patients always make a 100 per cent recovery. He has either to see his first day of practice or is in retirement. Every conscientious man in active work has periods of mental depression because of his failures.

Action recently brought against a surgeon in this state and reviewed by the Medical Advisory Committee brings out the following pertinent facts:

First.—A chronic lesion can become an acute one and conversely an acute one can become chronic.

Second.—In all conditions, acute or chronic, careful taking of a history of both past and present illnesses is essential before an operation.

Third.—Examination and confirmatory diagnosis should be made by the operating surgeon within the twenty-four hours preceding surgical treatment. Even though he has full confidence in the ability of the referring physician, the consulting surgeon should make his own diagnosis in order to plan his operative procedures.

If one remembers these three facts fewer operations will be performed without justification. Moreover, less censure will be meted out to the profession because of poor results following surgical intervention.

Statistics and numbers of cases should not be a substitute for sound judgment.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Sheriff Beihoffer, Strong Foe of Quacks, Dies Suddenly

Alfred T. Beihoffer, sheriff of McLeod county, Minnesota, for the past twelve years, died suddenly Sunday, October 17, 1938, while pheasant hunting near Wood Lake with a number of friends. Sheriff Beihoffer, while not enjoying the best of health, the past few months, was active in his office the day before his death. He suffered a heart attack while sitting in his car and died in a few moments.

Sheriff Beihoffer was known throughout his county as a sincere, hard-working and courageous law enforcement officer. He was best known to the medical profession for the splendid coöperation he gave the Minnesota State Board of Medical Examiners in the arrest and prosecution of quacks in his county. Two of his most notable cases were the cases of State of Minne-

sota vs. Robert McGraw and State of Minnesota vs. Herman Feenstra. McGraw was a well known Negro quack who was twice prosecuted at Glenwood and escaped conviction both times. McGraw was fined and sent to jail at Glencoe and left the state after serving his jail sentence. Feenstra was arrested by Sheriff Beihoffer in August, this year, after he had disappeared and forfeited a $2,500 cash bond at Brookings, South Dakota. He was sentenced to four years at Glencoe on a charge of criminal abortion.

Sheriff Beihoffer was born July 17, 1882, in Glencoe township, McLeod county. He spent his entire life in his home county. He is survived by his widow, Mrs. Alice Beihoffer, a son, Arnold, his 85-year-old father, one brother and four sisters, including Mrs. S. E. Allen, welfare worker for McLeod county.

In addition to the tragic loss suffered by his family, the people of McLeod county and the state of Minnesota have lost a faithful public servant, and the medical profession a loyal friend, in the death of Sheriff Beihoffer.

Minneapolis Woman Found Not Guilty of Obtaining Morphine from Physicians by Fraud and Deceit

Re: State of Minnesota vs. Helen Genevieve Rudd

After deliberating more than nineteen hours, a jury in the court of the Honorable Mathias Baldwin, Judge of the District Court, Minneapolis, found Helen Genevieve Rudd not guilty of obtaining morphine by fraud, deceit and misrepresentation under the new 1937 Minnesota Uniform Narcotic Drug Act.

The defendant was arrested July 7, 1938, following a joint investigation of the matter by the Federal Bureau of Narcotics and the State Board of Medical Examiners. The defendant has been in the Hennepin county jail since that time in default of bail. About a week before her trial began, she entered a plea of guilty to the charge before Judge Day, but upon being questioned by the Court prior to being sentenced stated she was unable to state the circumstances surrounding the obtaining of the two prescriptions that were the basis of the charge. Thereupon the Court ordered the plea of guilty stricken and the case set for trial.

The case was well tried for the state by Mr. Arthur Markve, assistant county attorney. The evidence offered by the State showed that the defendant had been attended by six Minneapolis physicians from the middle of April, 1938, and June 30, 1938, a period of six weeks. She was complaining of pain that indicated to each of the physicians called that she had a kidney stone. From five of these physicians she received morphine either in the form of hypos or by prescription. She received twelve prescriptions for morphine from four different physicians in thirteen days, May 6 to May 19, also one on June 30, a total of 78¼ gr. One physician testified that he wrote a prescription on May 6 and another on May 7 after the defendant had stated to him that she had lost the first one. This was denied by the defendant; she admitted getting the prescription but denied she stated she had lost the first one.

The defendant was convicted in Federal court in Minneapolis in December, 1934, on a charge of forging and altering narcotic prescriptions. She served fourteen months in the Federal Industrial Institution for Women at Alderson, West Virginia, on that charge. She is married and lives with her husband and one daughter. At the time of her arrest this year her address was 2527 First Avenue South, Minneapolis. She is thirty-nine years of age, about 5 feet 2 inches in height and weighs about 155 pounds. She appears to be older than the age stated.

The State Board of Medical Examiners urges every physician to refrain from administering, furnishing or prescribing morphine for this woman. If a call is made for a physician, he should insist on a complete examination, including x-ray, and hospitalization, if necessary, before any narcotic is given.

ALCOHOL IN RELATION TO TRAFFIC ACCIDENTS

Richard L. Holcomb, Evanston, Ill. (*Journal A. M. A.*, Sept. 17, 1938), reports the results of a study of the drinking of drivers involved in personal injury accidents and of the drinking of drivers in the general population. The second study served as a control of the first, allowing conclusions to be drawn as to the part alcohol plays in accidents. A total of 270 persons were tested in the first study. Drivers involved in personal injury accidents who accompanied the persons injured to a hospital or drivers who themselves were injured were tested by urinalysis for alcohol. A total of 1,750 persons were tested in the second study. Drivers were chosen at random from an area comparable to that of the first study. A complete testing laboratory, with the Harger "drunkometer," was set up in a trailer, allowing breath tests for alcohol to be made immediately. 1. The highest percentage of drinking drivers occurs in the early morning hours and over the week-end. 2. The largest number of drinking drivers occurs in the early evening and over the week-end. 3. The peak age for drinking drivers is from 25 to 30. 4. Women drink and drive as much as men when the number of women driving at various hours of the day is considered. 5. The percentage of drinking drivers in the general population varies as does the percentage of drinking drivers in the personal injury accident group but falls considerably lower at all times. 6. The percentage or number of drivers involved in personal injury accidents varies as does the percentage or number of drinking drivers. 7. As the blood alcohol content increases, the number of drivers appearing in the personal injury accident group increases out of all proportion over that in the general driving population. 8. As alcohol increases, accidents increase and at a rate somewhat proportionate to the increase in alcohol. 9. Equal percentages of drinking drivers are found in the accident group and in the general population group at a point near 0.5 part of alcohol per thousand parts of blood, indicating that alcohol in that amount is not necessarily a significant cause of accidents. 10. The data gathered in this study confirms a self-evident fact, that alcohol is a major cause of automobile accidents.

OF GENERAL INTEREST

Dr. Roy A. Hoffman of Minneapolis was married on October 16 to Miss Lolita B. Wilkinson of Cloquet.

* * *

Dr. John C. Fueling of Bovey is taking a postgraduate course at Columbia University.

* * *

Dr. A. R. Ellingson of Detroit Lakes was recently elected a fellow of the American College of Surgeons.

* * *

Dr. O. F. Mellby of Thief River Falls has been named chief of staff at Mercy Hospital.

* * *

Dr. Stanley Peters of Virginia has moved to Silver Creek, N. Y.

* * *

Dr. O. H. Jones has opened offices in Madison Lake for the practice of medicine. He recently completed his interneship at St. Mary's Hospital, Minneapolis.

* * *

Dr. Carl G. Wingquist has opened offices at Crosby. He formerly practiced at Carlton, Minnesota, and Los Angeles, California.

* * *

Dr. Harold Hullsiek of Saint Paul has resumed practice following an absence of four months from his office.

* * *

Dr. George Kaiser of Saint Paul has become associated with Dr. W. E. Macklin of Litchfield. Dr. Kaiser is a recent graduate of the University of Minnesota medical school.

* * *

Dr. E. H. Hansen, formerly of Minneapolis, has opened offices in Marshall. Dr. Hansen graduated from Tulane University, and served his interneship at the City and County Hospital in San Francisco.

* * *

Dr. W. E. Richardson of Philip, South Dakota, has opened an office at Rushford, for the practice of medicine. Dr. Richardson practiced at Slayton and Pipestone, before going to Philip, South Dakota.

* * *

Dr. L. F. Hawkinson, who has been associated with the Brainerd Clinic at Brainerd, Minnesota, will leave November 15 for Oakland, California, where he will establish practice.

* * *

Dr. I. L. Oliver of Graceville was recently elected to the American College of Surgeons and attended the meeting in New York City, where he received his fellowship.

* * *

Dr. John East has located in Northome for the practice of medicine. He is a graduate of the school of medicine of the University of Oklahoma, and served his interneship at Ancker Hospital, Saint Paul.

Dr. L. J. Hoyer, formerly of Howard Lake, has located at Windom. Dr. Hoyer recently completed a postgraduate course in surgery and bone fracture at the Cook County Graduate School of Medicine at the Mayo Clinic.

* * *

Dr. D. J. Jacobson, formerly of Blackduck, has located at Bemidji, where he will continue the practice of medicine. Before leaving Blackduck, Dr. Jacobson was the guest of honor at a dinner given by the Blackduck Community Club.

* * *

Dr. Harlow B. Thompson has opened offices at Ada for the practice of medicine. He is a graduate of the medical school of the University of Oregon, and served his interneship at the Tacoma General Hospital and Pierce County Hospital at Tacoma, Washington.

* * *

Dr. Samuel T. Sandell has become associated with Dr. H. E. Binet of Grand Rapids. Dr. Sandell is a graduate of the medical school of the University of Minnesota and served interneships at Ancker Hospital in Saint Paul, and the Glen Lake Sanatorium in Hennepin County.

* * *

The American Medical Association and the National Broadcasting Company are broadcasting at 1 p. m. each Wednesday, over the Blue Network, a radio program entitled "Your Health." The program is not one of health talks, but of dramatization written and produced by radio artists prepared from information furnished by the Bureau of Health Education of the American Medical Association.

* * *

Graduate Fellowships in Anesthesiology have been established by the Medical School and Graduate School of the University of Minnesota for physicians who desire to prepare themselves for the practice of this specialty. The fellowships offer an abundance of clinical training in all types of local, regional and general anesthesia and gas therapy, and also adequate related graduate work in chemistry, anatomy, physiology, pharmacology. Applicants must have served at least one year in a rotating interneship.

* * *

The Squibb Institute for Medical Research, a new $750,000 modern building especially adapted for research, at New Brunswick, New Jersey, was dedicated with appropriate ceremonies October 11, 1938. Air conditioning and accurate control of temperature and humidity will make research possible the year around. The aim of the founders of the Institute is to create in the medical and biological fields an industry-supported research enterprise analogous to the Bell Telephone and General Electric laboratories in the sphere of physics.

Dr. Litzenberg Honored

An appreciation dinner was given in honor of Dr. Jennings C. Litzenberg on the evening of October 14, 1938, at the Minikahda Club, Minneapolis, by some 200 former pupils and friends in celebration of his completion of twenty-five years as chief of the Department of Obstetrics and Gynecology of the University of Minnesota.

Following his gradution from the University of Minnesota medical school in 1899, Dr. Litzenberg acted as assistant to Dr. L. J. Cooke, the medical director of athletics, before he specialized in obstetrics and gynecology. It was fitting that Dr. Cooke should act as Master of Ceremonies at the testimonial dinner, which he did with much display of wit and humor. After-dinner speeches were made by Dr. Lee W. Barry of Saint Paul, who outlined changes in obstetrical procedures which have taken place in the past twenty-five years; by Dr. William A. O'Brien, who wittily described a picture of Dr. Litzenberg projected on a screen and purported to be the portrait of the honored guest to be presented to the University; by Dr. John L. McKelvey, who is Dr. Litzenberg's successor as chief of the department, in which he paid graceful tribute to his predecessor, giving him a large share of the credit for the low infant and maternal mortality in Minnesota. Although not appearing on the printed program, Mr. John Powell, a life-long friend, contributed a nice tribute to Dr. Litzenberg, and all those present were amused by the witty remarks of Dr. Litzenberg's son, Carl, a professor of English at the University of Wisconsin. In responding, Dr. Litzenberg disclaimed credit for the high standing of obstetrics in Minnesota, and gave credit to the ability of his departmental staff.

The dinner, sponsored by a committee of which Dr. S. B. Solhaug was chairman, was a great success and all who attended derived great satisfaction from being able to show their appreciation of "Litz."

Dedication of Mayo Foundation House

On September 23, at Fourth Street and Seventh Avenue Southwest in Rochester, in the stone house which had been their home since 1917, Dr. and Mrs. William J. Mayo received members of the staffs of The Mayo Clinic and The Mayo Foundation in order formally to dedicate the building and grounds as Mayo Foundation House.

On the occasion, short addresses were delivered by representatives of The Mayo Foundation, The Mayo Clinic and The Mayo Properties Association. Dr. Mayo responded in part as follows:

"When my brother and I built our homes, we built them not merely for the purpose of living in them ourselves, but with the idea that they should be of such character as would make them suitable gathering places where the staff of the Clinic and the fellowship men might meet men of science from this country and abroad and cultivate those social contacts which are so important a part of professional life.

"And so with this Foundation House, which we have given over to be used for continuation and extension of educational and related social functions which are in

(Continued on Page 812)

In Memoriam

Martin C. Bergheim

1886-1938

DR. Martin C. Bergheim, Hawley, Minnesota, died October 4, 1938, of bronchopneumonia, at the age of fifty-two.

Dr. Bergheim was born in Madison, South Dakota, January 23, 1886. He graduated from St. Olaf College in 1912. The following three years he acted as principal and athletic coach at Lamberton, Minnesota. In 1916 he entered the University of Minnesota medical school and graduated in 1919, serving as interne at the Providence Hospital at Detroit, Michigan. He was a member of the Phi Beta Pi medical fraternity.

Dr. Bergheim practiced medicine at Raymond, Minnesota, for a year before locating in 1921 at Hawley, where he had since practiced. In 1922 he contracted scarlet fever and his health was permanently impaired as a result although he carried on an active practice.

A member of the Lutheran Church, Dr. Bergheim also belonged to the Masonic and Eastern Star lodges. He was a member of the Clay-Becker County Society, the Minnesota State and American Medical Associations.

Dr. Bergheim is survived by his widow; two daughters, Gail Marie and Jeanne Marie; his father, C. N. Bergheim; two brothers, Richard and Nordahl of Madison, South Dakota; and six sisters.

Dr. Bergheim's kindness and patience in dealing with his many patients will long be remembered in the community in which he lived.

F. C. Bowman

1849-1938

DR. F. C. Bowman, of Duluth, passed away on October 4, 1938, at the age of eighty-nine.

Dr. Bowman was born on a farm at Hebron, Maine, and in 1857 came to Minnesota, attending high school in Litchfield, Minnesota. In 1875 he began the study of architecture at the University of Minnesota, earning his way by working as a janitor, carpenter, assistant chemist and contractor. In 1879 he began the study of medicine at the Hahnemann Medical School.

Dr. Bowman arrived in Duluth in March, 1881, having had to pawn his watch to finance the price of a railway ticket to Minnesota. The first few months of practice in Duluth were difficult and it was only through the assistance of Luther Mendenhall, a pioneer Duluth banker, that he was able to continue practice.

During the more than half century of practice in Duluth, Dr. Bowman was active in civic affairs. In the late 1880's he was a member of the Board of Education of Duluth, and in the 1890's was a member of the State Board of Medical Examiners.

Dr. Bowman was a member of the First Methodist Church and of the Scottish Rite of Duluth, and also

of the Golden Fleece lodge, A. F. and A. M. of Litchfield. For many years he was a member of the Saturday Lunch Club also. He is survived by his widow; a daughter, Mrs. L. H. Jones of Coral Gables, Florida; two sons, Lawrence and Leslie, of Duluth.

Henry Martyn Bracken

1854-1938

DR. Henry Martyn Bracken, former Secretary of the Minnesota State Board of Health and a resident of Minneapolis from 1885 until 1923, died at his home in Claremont, California, September 25, 1938, at the age of eighty-four.

Dr. Bracken was born February 27, 1854, the son of a physician and as a boy lived in Jersey, Ohio, where he received his preliminary education except for a year at Elders Ridge Academy. He taught in a summer school at the age of seventeen and then returned to the Academy, where he graduated in 1872, delivering a Greek oration. His father died the same year and he returned to teaching at Boonton, New Jersey, but in 1874 entered the medical department of the University of Michigan for a year. After teaching another year he entered the College of Physicians and Surgeons, New York, where he graduated in 1877.

Following graduation Dr. Bracken went to Venezuela as mine surgeon, but shortly left for Edinburgh for further medical study and in 1879 passed the examination of the Royal College of Surgeons. After spending the summer as physician in a boys' boarding school at Uppingham-by-the-Sea, he sailed as ship surgeon on the "Moselle" to Central and South America and the West Indies. During the three years as ship surgeon he contracted both yellow fever and malaria.

In the fall of 1882, Dr. Bracken returned to practice in a New England town, but being dissatisfied went to Sonora, Mexico, in 1884, as camp surgeon in a mining camp. Owing to the activities of the Apaches under Geronimo, the mines closed in 1885 and Dr. Bracken returned to New York for more postgraduate study. In December, 1885, he came to Minneapolis with his wife whom he had married in 1884 before going to Mexico.

Upon organization of the Medical School of the University of Minnesota in 1887, Dr. Bracken was appointed Professor of Materia Medica and Therapeutics and lectured also on Public Health and Preventive Medicine. He remained on the faculty until 1907 when he resigned to devote his time to the State Board of Health. He was elected to this board in 1895 and became its Secretary and Executive Officer in 1897, succeeding Dr. Charles N. Hewitt. During his incumbency, which lasted until 1919, the present divisions of the board, with the exception of the Division of Child Hygiene, were created. The mortality from typhoid, diphtheria, and the other contagious diseases of childhood and also from tuberculosis were unbelievably high at the turn of the century and proved a serious problem in State Board activities. Dr. Bracken was particularly concerned with the care of lepers in Minnesota and was instrumental in the establishment of a national leprosarium. He took a leading part in national health affairs and in 1912 was president of the Conference of State and Provincial Health Authorities of North America.

In 1916, Dr. Bracken volunteered his services to the medical corps of the British Navy but was not accepted on account of his age. Again in 1917, he volunteered his services to the Medical Corps of the United States Army, but was considered of much greater value in his official position. On September, 1919, he retired as State Health Officer and was commissioned as surgeon in the Reserve Corps of the United States Public Health Service and was assigned to the Veterans' Bureau. In 1923, he resigned and moved to Claremont, California, where he maintained his interest in Public Health, lecturing at Pomona College, and making a thorough review of the official records of the Minnesota State Board of Health from 1872 through 1936.

Dr. Bracken took an active part in the American Medical Association's public health program, was a member of the first Board of Directors of the National Tuberculosis Association, and in 1906 organized the Minnesota's Association for the Prevention and Relief of Tuberculosis, now the Minnesota Public Health Association. He also organized the Minnesota State Sanitary Conference and was its secretary.

A few years ago Dr. Bracken returned for a visit with his nephew, Dr. William Henry Condit of Minneapolis. At this time he appeared hale and hearty, attended with Dr. Chesley, present secretary of the State Board of Health, several county society meetings, and enjoyed meeting many of his old friends. Besides his nephew, Dr. Condit, Dr. Bracken is survived by his widow.

John Folta

1901-1938

DR. John Folta of Ceylon, Minnesota, died suddenly from coronary thrombosis at the home of his brother, Andrew Folta, in Minneapolis, on October 14, 1938.

Dr. Folta was born in Morrison County, Minnesota, in 1901, the son of Adam and Anna Folta, his parents being natives of Austria. At the age of sixteen he entered Baldwin-Wallace College near Cleveland, Ohio, and later Berea College, where he received his B.A. degree in 1923. He received his M.D. degree at the University of Minnesota Medical School in 1929, and after serving one year as interne in St. Luke's Hospital, Duluth, he became associated with Dr. Arnt G. Anderson, Minneapolis, for a year.

Dr. Folta began practice at Ceylon in 1930 and the

following year purchased the practice and hospital of Dr. Bailey when the latter moved to Fairmont. Since July, 1937, Dr. I. Fisher had been associated with him in practice.

In 1930 Dr. Folta married Dorothy Thompson of Duluth. He is survived by his widow; two sons, Russell, aged 6, and Richard, aged 3; his father, three brothers and a sister.

Dr. Folta was keenly interested in athletics, having played football in his student days, and had gone to Minneapolis chiefly to attend the Minnesota-Michigan game. He was a member of the Masonic Lodge of Sherburn, the Blue Earth Valley Medical Society, Minnesota State and American Medical Associations.

Albert Henry Parks

1880-1938

DR. Albert Henry Parks was born in Battle Creek, Michigan, April 15, 1880, the son of Reuben B. and Celia Burr Parks. He was graduated from the Battle Creek High School in 1898 and after two years at Albion College he entered the University of Michigan, where he graduated June 25, 1904, receiving a Bachelor of Arts degree. He received his M.A. and M.D. degrees from Northwestern University in 1906. After serving his internship in St. Luke's Hospital, Chicago, he was licensed to practice in the State of Minnesota on April 12, 1907 and in California, February 23, 1922.

Dr. Parks was a member of the Hennepin County Medical Society, Minnesota State Medical Association, American Medical Association, Sigma Chi Fraternity, and the Phi Beta Pi Fraternity.

During the period from 1908 to 1915 when Dr. Parks was assistant city physician, Hopewell Hospital for tuberculous patients was opened and he was put in charge of the medical treatment of these patients, also acting as superintendent of the institution.

He was a founder and first president of the Lake Harriet Commercial Club, a founder and first president of the Lake Harriet Lodge A. F. and A. M. 277; and from 1910 to 1911 was national president of the Phi Beta Pi medical fraternity.

In 1913 and 1914 he served as alderman of the 13th Ward, resigning in 1915 to give his attention to practice.

In June 1917 he was appointed a member of the local draft board of the 13th Ward of Minneapolis. In June 1918 he resigned and on August 1 was commissioned captain in the Medical Section of the Officers' Reserve Corps, receiving his honorable discharge on April 15, 1919.

Dr. Parks was appointed chief of the Surgical Service, Division "B" of the General Hospital Staff, Minneapolis, January 14, 1918. He was a member of the Staff of St. Barnabas Hospital for five years and was a member of the Surgical Staff of Asbury Hospital from the beginning of his practice until his retirement, serving as Chief of Staff during the year 1932. The last years of his surgical practice were spent here, where he endeared himself to the hospital personnel and to the staff of doctors. He was appointed a member of the Board of Public Welfare during the year 1923.

The following articles were written by him:

Among his written contributions may be listed: The Medico Legal Expert, written for the Medico Legal Journal; Brotherhood, written for the Phi Beta Pi Quarterly; and Economic Therapeutics, read before the Asbury Hospital Staff and the Hennepin County Medical Society and published in Minnesota Medicine in 1932.

Dr. Parks was married to Katherine Barrett, a graduate nurse from Abbott Hospital, Minneapolis, on September 1, 1909. Their only child is a daughter, Mrs. Jean Parks Forrest of Minneapolis.

Dr. Parks used unusual foresight in preparing himself for his profession, obtaining his B.A., M.A., and M.D. degrees and serving his internship in one of the leading hospitals. When he began to practice in the City of Minneapolis he continued to reëducate himself by his association with the General Hospital. He carried out a program for the young physician that was ideal. In his private practice from the very beginning there was ample evidence of his good preparation and that he was applying the highest ethical principles of medical practice.

Dr. Parks felt, also, a civic duty which was shown by his willingness to serve the public hospitals, the public welfare board, and the city council.

He was devoted to his family and knowing that the condition of his health might separate them without warning, he, as long ago as 1929, wrote and sealed a farewell message to his wife and daughter, paying beautiful and well deserved tribute to them both. He died August 30, 1938, after an illness of five years.

One of Dr. Parks' outstanding characteristics was his praise of others and his personal modesty. Another virtue was his great generosity. He will be remembered for his gracious manner, his thoughtfulness of others, and his pleasant companionship, as well as for his painstaking care of his patients and his scientific attainments.

Dr. Parks was a colorful figure in his profession, a clever surgeon, an astute diagnostician, and an ideal consultant. My association with him in surgery at Asbury Hospital during his last active years was an inspiration.

CLAUDE C. KENNEDY.

OF GENERAL INTEREST

Mayo Foundation House

(Continued from Page 810)

the best interest of the purposes of the Foundation. This house was built with the intention of such ultimate use: fireproof, of large size, suitable for the development of the opportunities which we hope will be realized."

The donors have provided a sufficient endowment for maintenance of the house and garden and have taken up their residence in a new and smaller dwelling. Their former home, now Mayo Foundation House, already is in daily use as a meeting place for seminars and for other groups engaged in educational activities.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR NOVEMBER

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis (810 kilocycles or 370.2 meters) and Station WLB, University of Minnesota (760 kilocycles or 395 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

November 5 Good Posture.
November 12 Gall Bladder Disease.
November 19 Sinusitis
November 26 Development of Teeth.

SCIENTIFIC EXHIBIT AMERICAN MEDICAL ASSOCIATION

Application blanks are now available for space in the Scientific Exhibit at the St. Louis Session of the American Medical Association, May 15-19, 1939. Attention is called to the fact that the meeting is a month earlier than usual, and applications close January 5, 1939. Blanks will be sent on request to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn St., Chicago, Ill.

PAN-PACIFIC SURGICAL ASSOCIATION

The third Congress of the Association will be held in Honolulu, September 15 to 28, 1939. An invitation is extended to all surgeons in the State Association to take part in this meeting, which will be attended by outstanding surgeons from Australia, New Zealand, China, Japan, Java, Canada and the United States. There will be sections on fractures and orthopedics, general surgery, gynecology, neurosurgery, ophthalmology, otolaryngology, plastic surgery, thoracic surgery and roentgenology. A visit to the "Paradise of the Pacific" is an additional attraction. Dr. Forrest J. Pinkerton, Young Building, Honolulu, is secretary of the Association.

NORTH DAKOTA SOCIETY OF OBSTETRICIANS AND GYNECOLOGISTS

The biannual meeting of the North Dakota Society of Obstetricians and Gynecologists was held Friday, October 28, at the Fargo Country Club, Fargo, North Dakota.

Dr. W. F. Mengert, of the University of Iowa Medical School, spoke on "Toxemias of Pregnancy" and Dr. J. C. Litzenberg, Emeritus Professor of the Department of Obstetrics and Gynecology of the University of Minnesota, addressed the meeting. Case reports were presented by Drs. J. F. Hanna, G. W. Hunter, B. M. Urenn and J. R. Dillard.

Officers for the ensuing year are: Dr. J. F. Hannar, Fargo, president; Dr. John H. Moore, Grand Forks, vice pesident; and Dr. A. C. Orr, Bismarck, secretary-teasurer.

SCOTT-CARVER SOCIETY

At the Scott-Carver Medical Society meeting held in Montgomery, October 11, Dr. George Eitel, Minneapolis, spoke on "Traumatic Surgical Emergencies," and Dr. Ernest Meland, Minneapolis, talked on "Urological Emergencies."

WABASHA COUNTY SOCIETY

The seventieth annual meeting of the Wabasha County Medical Society was held at Wabasha, Thursday afternoon and evening, October 6, 1938.

At the business session, the following officers were elected for the coming year:

President—Dr. B. J. Bouquet, Wabasha
Vice President—Dr. E. W. Ellis, Elgin
Secretary-Treasurer—Dr. W. F. Wilson, Lake City
Delegate to State Association—Dr. E. C. Bayley, Lake City
Alternate—Dr. R. H. Frost, Wabasha
Censor for three years—Dr. G. W. Holt, Wabasha
Censors continuing in office—Dr. J. R. Slocumb, Plainview, and Dr. B. A. Flesche, Lake City.

One new member was received into the society, Dr. Robert A. Glabe of Plainview.

Dinner was served at Hotel Anderson through the courtesy of the Wabasha members. Among the guests were Dr. A. J. Chesley and Dr. R. N. Barr of the Minnesota Department of Health, and Dr. Roy Flannagan, of Richmond, Virginia, liaison officer of the relief forces of that state. Upon invitation, each of these guests made a few appropriate remarks.

At the scientific session in the evening, the following program was presented:

President's Address—"Coöperation Within the Society"—Dr. H. T. Sherman, Plainview.
"Epidemic Encephalitis"—Dr. Gordon R. Kamman, Saint Paul.
"Granulocytopenia, With Case Reports"—Dr. B. A. Flesche, Lake City.
"Practical Points in Pediatric Practice"—Dr. Edward Dyer Anderson, Minneapolis.
"Roentgen Therapy in Malignant Disease"—Dr. W. C. Popp, Mayo Clinic, Rochester.

The Women's Auxiliary held their sessions in connection with this meeting. Entertainment for the ladies was provided at the home of Dr. and Mrs. Ochsner.

In all, there were thirty-two in attendance, including nineteen physicians, three dentists and ten doctors' wives.

WASHINGTON COUNTY

The regular meeting of the Society was held September 13. A report was given by Dr. E. V. Strand,

Bayport, and by the secretary of the State House of Delegates meeting held in Saint Paul, September 11.

The scientific program was given by Dr. Gordon R. Kamman, Saint Paul, who devoted most of his time to a consideration of vitamins and then discussed some recent experiences with acute encephalitis.

Dr. Leo James Conlin, Lake Elmo, was elected to society membership.

* * *

The guest speaker at the meeting held on October 11 was Dr. Raymond N. Bieter of the Medical School, who spoke on "The Chemistry and Therapeutic Use of Sulfanilamide."

The booklet on Maternal Care and Complications edited by Dr. Fred Adair and distributed by the Minnesota State Department of Health through Dr. Chesley, was given to the society members.

Mr. Manley Brist of Saint Paul was a welcome guest.

WOMAN'S AUXILIARY

Mrs. W. B. Roberts, President
2735 Irving Avenue South, Minneapolis.
Mrs. E. V. Goltz, Press and Publicity, St. Paul, Minn.

Mrs. William B. Roberts, State President of the Women's Auxiliary of the Minnesota State Medical Association, was the guest delegate of the Auxiliary to the northern Minnesota district August 29 and 30, which was held in Crookston. The Northern Minnesota District Medical Society met at that time and members of the Auxiliary were entertained delightfully by the members of the Auxiliary of the Red River Valley Medical Association. Women from various parts of the northern territory of Minnesota attended and special guests besides Mrs. Roberts were Mrs. E. M. Hammes and Mrs. George Earl of Saint Paul. Mrs. Roberts was the house guest of Mrs. J. F. Norman, past president of the State Auxiliary. An attractive luncheon was held at the Hotel Crookston for the visitors, and Mrs. Roberts addressed the group. Following the luncheon a tour was arranged for the visitors, taking in the interesting points of the city and community. Later in the afternoon a bridge-tea was held at the home of Mrs. O. E. Locken. Honors in bridge were won by Mrs. Clarence Jacobson, Mrs. H. H. Hodgson and Mrs. Roberts. Presiding at the tea table, which was attractively arranged with zinnias, were Mrs. C. L. Oppegaard and Mrs. B. Borreson of Thief River Falls. Mrs. C. L. Oppegaard was the social chairman and was assisted by Mrs. G. A. Morley and Mrs. C. G. Uhley (registration); Mrs. O. L. Bertelson and Mrs. M. O. Oppegaard (transportation); Mesdames Hodgson, L. L. Brown, O. K. Behr, R. O. Sather and B. Borreson of Thief River Falls (luncheon); and Mesdames J. F. Norman, W. G. Paradis, W. F. Mercil, S. H. Stuurmanns of Erskine and Mrs. O. E. Locken of Crookston (bridge-tea). In the evening the doctors and their wives enjoyed a dinner together. The Red River Valley Auxiliary is noted for its hospitality and sociability, and Mrs. Roberts reports a most interesting and enjoyable meeting.

The members of the Woman's Auxiliary to the Clay-Becker Medical Society had their regular summer meeting, August 15, when the Clay-Becker Medical Society convened. A joint dinner was held at the Pettibone Lodge, which was followed by a talk by Dr. J. M. Hayes, who spoke of the work done by the organization, and also on the technical subject "Gallbladder Diseases." The business session of the Auxiliary was devoted mainly to philanthropic plans for the coming winter. Attending from Detroit Lakes were Mrs. L. H. Flancher, Mrs. Arnold Larson, Mrs. O. O. Larsen and Mrs. A. R. Ellingson; from Hawley, Mrs. C. W. Simison, Mrs. V. D. Thysell and Mrs. M. C. Bergheim. After the business session cards were enjoyed by the members.

Mrs. Roy Andrews, a member of the Blue Earth County Auxiliary, attended the annual American Medical Association meeting in San Francisco.

On September 26 the Woman's Auxiliary of the Minnesota State Medical Association held its first Executive Board meeting at the Minikahda Club, Minneapolis, at 10:30 a. m. Mrs. William Roberts, the president, presided. Reports of the county presidents were read and the activities for the year discussed. Following the meeting a luncheon was served at the club with Mrs. Charles C. Tomlinson of Omaha, Nebraska, president of the Women's Auxiliary of the American Medical Association, the honored guest. Dr. J. M. Hayes, president of the Minnesota Medical Association, spoke. Following the luncheon Mrs. J. M. Hayes was hostess at a beautifully arranged tea for the visitor, at her home, 2821 Benton Boulevard. Mrs. Martin Nordland of Minneapolis was the social chairman.

The Woman's Auxiliary of the Mower County Medical Society held its fall meeting October 3 at the Austin Country Club. Thirteen members and four guests were present and luncheon was served at one o'clock followed by a business meeting. Mrs. Paul Robertson, president, presided and gave a report of the state board meeting held in Minneapolis September 25. Bridge followed and prizes were won by Mrs. Paul Leck and Mrs. G. E. Hertel. Out-of-town guests were Mrs. A. E. Henslin of LeRoy and Mrs. J. M. Thomson of Brownsdale The next meeting will be October 31.

A tea held at the home of Mrs. Edward Schons, Saint Paul, September 26, honored the national president of the Woman's Auxiliary, Mrs. Charles C. Tomlinson of Omaha. The tea was given by the members of the Ramsey County Women's Auxiliary.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

YOU CAN SLEEP WELL. Edmund Jacobson, M.D. 269 pages. Illus. Price, cloth, $2.00. New York: McGraw-Hill Book Co., Whittlesey House, 1938.

CANCER OF THE BREAST AND CANCER OF THE UTERUS. By Marion Ellsworth Anderson, M.D. 63 pages. Illus. Paper cover. Clinton, Iowa: Franklin Press, 1938.

EXPERIENCES IN THE MANAGEMENT OF FRACTURES AND DISLOCATIONS. Based on an analysis of 4,390 cases. By the Staff of the Fracture Service of the Massachusetts General Hospital. Philip D. Wilson, M.D., General Editor. 1036 pages. Illus. Price, cloth, $15.00. Philadelphia: J. B. Lippincott & Co., 1938.

ANUS, RECTUM, SIGMOID COLON. Diagnosis and Treatment. By Harry Ellicott Bacon, B.S., M.D., F.A.C.S., F.A.P.S. Assistant Professor of Proctology, Temple University School of Medicine; Assistant Professor of Proctology, Graduate School of Medicine, University of Pennsylvania; Visiting Proctologist, St. Luke's and Children's Hospitals, etc. 855 pages. Illus. Price, cloth, $8.50. Philadelphia: J. B. Lippincott & Co., 1938.

A HISTORICAL CHRONOLOGY OF TUBERCULOSIS. Richard M. Burke, M.D., State Veterans Hospital, Sulphur, Okla. 84 pages. Price $1.50, cloth. Springfield, Illinois: Charles C. Thomas, 1938.

THE 1938 YEAR BOOK OF PHYSICAL THERAPY. Richard Kovacs, M.D., Editor. Clinical Professor and Director of Physical Therapy of New York Polyclinic Medical School and Hospital; Attending Physical Therapist Manhattan State, Harlem Valley State and West Side Hospitals, etc. 486 pages. Illus. Price, $2.50, cloth. Chicago: Year Book Publishers, 1938.

PRACTICAL MICROBIOLOGY AND PUBLIC HEALTH. William Barnard Sharp, S.M., M.D., Ph.D. Professor of Bacteriology and Preventive Medicine, Medical Department of the University of Texas; Visiting Bacteriologist John Sealy Hospital, Galveston, etc. 492 pages. Illus. Price $4.50, cloth. St. Louis: C. V. Mosby Co., 1938.

ENDOCRINE THERAPY IN GENERAL PRACTICE. Elmer L. Sevringhaus, M.D., F.A.C.P. Professor of Medicine, University of Wisconsin; Editor Department of Endocrinology, Year Book of Neurology, Psychiatry and Endocrinology. 192 pages. Illus. Price, $2.75, cloth. Chicago: Year Book Publishers, 1938.

ALLERGIC DISEASES: THEIR DIAGNOSIS AND TREATMENT. By Ray M. Balyeat, assisted by Ralph Bowen. Illustrated with 132 engravings, including 8 in colors. 4th ed., rev. and enl. $6.00. Philadelphia: F. A. Davis Co., 1936.

In writing this book the author seems to have had in mind a manual for allergic patients. However, much of the text seems to be more scientific and more specialized than most laymen would be able to understand. For the professional man the book contains a large fund of information, but there is much of it that is simpler than a physician needs. There is a wealth of information in this book, but it is not as available as it should be either for the doctor or for the patient. Many of the points are illustrated with case histories, which is not good for laymen, as it serves as a patent medicine advertisement. There is advice given in this book which does not seem in agreement with the feeling of the profession as a whole; i.e., birth control is recommended for people with migraine as a means of preventing it in the offspring. This seems to a reviewer as radical treatment for a condition that is an inconvenience rather than a disease. On the whole this volume is not particularly recommended either for the patient or for the professional man.

DIABETES; A MODERN MANUAL. Anthony M. Sindoni, Jr., M.D. 240 p. charts, $2.00. New York: Whittlesey House, 1937.

This book is put out primarily to teach the diabetic patient how to take care of himself while under a physician's care. The material is well written and in simple language so that the intelligent diabetic individual can understand it. The section containing answers to typical questions asked of physicians should be a great help to the patient in having a better understanding of the disease and what is required of him to remain in good health. The section on diet including menus and recipes is very complete and well written. The book is one that is not only valuable for the patient, but is also of value to the physician who needs all the assistance he can get in handling the problem of diabetes.

JOHN R. MEADE, M.D.

A MANUAL OF OPERATING ROOM PROCEDURES. Alvina W. Hoppe, Science Instructor, Jewish Hospital, St. Louis, and Lucile M. Halverson, Supervisor of Operating Rooms, University of Minnesota Hospitals, Minneapolis. The University of Minnesota Press (Humphrey Milford, Oxford University Press, London), 1937. Price $2.00.

As the title indicates, this volume is intended for the surgical nurse in the operating room. The supervision of a modern operating room requires much attention to detail if an operation is to proceed smoothly. The duties of the operating room personnel are outlined in detail, the care of materials, the preparation of patients, tray set-ups and, under separate headings, instructions for practically all operations are given in

minute detail. Representing, as it does, the technic used in two outstanding hospitals, its pages reflect the careful thought given by the authoresses. The volume should be of great value to surgical nurses, particularly those in charge of operating rooms.

C. B. D.

MATERIA MEDICA AND PHARMACOLOGY. H. A. McGuigan and E. P. Brodie. 580 p. Illus. $2.75. St. Louis, Mosby, 1936.

This book is an outgrowth of Brodie's Materia Medica for Nurses, but is much more complete. It has left out many of the older drugs which were used without any basis, but which have been handed down as being of value. The book is well written and the subject matter well classified. The sections on the action of drugs on the nervous system and on the vascular system are very complete. The illustrations make it easier for the students to understand the actions of drugs. The book should make a very good textbook for both medical students and nurses.

JOHN R. MEADE, M.D.

ENDOCRINE THERAPY IN GENERAL PRACTICE. 192 p. illus., $2.75. E. L. Sevringhaus, M.D., F.A.C.P. Chicago: Year Book Publ. Co., 1938.

This small book does not attempt to cover the entire field of endocrine literature but manages, in an easy-to-read form, to simplify and correlate the most important fundamental facts to serve as a background for intelligent endocrine therapy by the general practitioner. The author fully understands that any book written about glandular therapy is quickly outdated.

One of the most likely criticisms of this volume will undoubtedly be that the handling of the material is too elementary. This criticism is valid; but nevertheless the same criticism will recommend the book to those practitioners who on looking up references in the field of endocrine therapy are likely to become perplexed by the confusion that exists in terms, nomenclature, indications, and dosages. A careful reading may well result in a better understanding of indications and avoid the dangers of enthusiastic overtreatment as a result of commercial exploitation of endocrine products.—M. L. STRAUS, M.D.

A PEDIATRICIAN IN SEARCH OF MENTAL HYGIENE. Bronson Crothers, M.D., New York, $2.00. The Commonwealth Fund, Oxford University Press, 1937.

The fascinating title of this small volume recommends it at once. Anyone—pediatrician or other—whose resurgent hopes send him forth on so commendable a search deserves company.

The author "starts with a general survey of the situation as it relates to the practice of medicine and then goes on in a rather casual way to discuss the medical school and the teaching hospital." He closes with a description of a scheme for coöperation between psychologist and pediatrician as worked out at the Children's Hospital in Boston. That the author has achieved a sympathy with the psychologist may be surmised from his comment on the enterprise: "With full expectation of harmony on both sides, friction became evident almost from the start. Since this friction has, we both now believe, led us to an adequate and effective measure of coöperation, it is I think worth considering."—E. C. HARTLEY, M.D.

GLASSES OF HIGHEST QUALITY

With Careful Attention Given to Correct Styling

N. P. Benson Optical Co., Inc.

Established 1913

Main Office: Minneapolis, Minn.

CLASSIFIED ADVERTISING

FOR SALE—X-ray machine in perfect order; has Coolidge tube and Bucky diaphragm. Will have x-ray man make installation. Complete for $295.00. Address A-51, care MINNESOTA MEDICINE.

FOR SALE—Quartz sun lamp with new burner. This lamp looks and operates like new. Will sacrifice for $95.00. Address A-52, care MINNESOTA MEDICINE.

FOR SALE—Medical and surgical library including Tice's Practice of Medicine, Callander's Surgical Anatomy, Crossen's Operative Gynecology. Also microscope and surgical instruments. Address Mrs. H. W. Froehlich, 1112 Eighth Avenue S. E., Minneapolis. Telephone—Gladstone 7729.

FOR SALE—Beautifully equipped doctor's office; records kept for years of a tremendous practice in most progressive small town in state. Lovely home for sale—optional. Reason for selling—doctor's death. Address A-53, care MINNESOTA MEDICINE.

PHYSICIAN'S ASSISTANT desires position. Eight years' experience, including therapy, laboratory, typing and collections. References. Address J. G. Ford, 934 Grand Avenue, Saint Paul. Telephone: Elkhurst 3045.

FOR SALE—Practice and office equipment of physician recently deceased. Southwestern Minnesota town in rich agricultural section. Excellent opportunity. Address A-45, care MINNESOTA MEDICINE.

GOOD LOCATION—Southern Minnesota town, population 1300. Nothing to purchase. Address A-54, care MINNESOTA MEDICINE.

WHY PAY HIGH OFFICE RENT when you can get more space and better accommodations for less money in the Elliot Building, 8th Street and 8th Avenue South, Minneapolis. Centrally located; convenient to hospitals and outside restricted parking zone. Equipped with x-ray and clinical laboratory. H. W. Quist, M.D., 732 Eighth Ave. So., Minneapolis, Minn.

Volume 21 DECEMBER, 1938 No. 12

THE ROLE OF INSECTS AND ALLIED FORMS IN THE TRANSMISSION OF DISEASES DUE TO FILTERABLE VIRUSES*

WM. A. RILEY, Ph.D.
Chief of the Division of Entomology, University of Minnesota
Saint Paul, Minnesota

THE fact that there exists among horses in Minnesota an epizoötic disease known technically as equine encephalomyelitis and that during the five summers preceding 1938 it affected approximately 50,000 of these animals and killed 10,000 of them on farms in this state is a matter of very serious concern for our farmers and through them it affects all of us as an economic problem.

Repeatedly during the course of the epizoötic in Minnesota and elsewhere the question has been raised as to whether this disease was transmissible to man. There have been a number of instances in which this seemed clearly indicated and Eklund and Blumstein (1938) report on six cases of "an unusual encephalitis occurring among farmers in Minnesota localities where equine encephalomyelitis was prevalent." The blood serum of one of three patients was shown by Dr. Ten Broeck, of the Rockefeller Institute, to neutralize the western strain of equine encephalomyelitis. Within the last few weeks there have been additional clear-cut demonstrations of this relationship. First, Fothergill, Dingle, Farber and Connerley reported that they had recovered the virus of the equine disease from the brain of a Massachusetts child who had succumbed to a case of encephalitis, during a period when there was an unprecedented outbreak of the horse disease. This finding was promptly confirmed by Webster and Wright, who described positive findings in four additional cases. They report that the virus from the brain tissue of human cases is highly infectious for mice by the nasal route and by injection. And now, Schoening, Giltner and Shahan, using virus originally obtained by Fothergill from the brain of a child, have infected two horses, and through failure to infect one which was immune to the so-called eastern virus, have shown that the Massachusetts cases in man are of the eastern type. Incidentally, they report that all five strains recovered by the Bureau of Animal Industry from Massachusetts horses during the outbreak of 1938 were definitely of this same eastern type.

This brings again to the foreground the question as to the method, or methods, of transfer of this and related diseases. There is general agreement today that these infections are due to filterable viruses and there are many workers who are convinced that they are transmitted in nature primarily or even solely by insects and allied forms. To what extent has this arthropod transmission been demonstrated and what species may be regarded as clearly under suspicion in this region?

It must be recognized at the outset that the problem is not a simple one. The fact that an insect is a blood sucker does no more than place it in a list of forms to be considered. The abundance of the species, its seasonal distribution in relation to the outbreaks of the disease, its ready access to diseased and healthy animals, frequency of blood meals and longevity, the ability of the virus to exist in the insect, and its particular host specificity are among the points which must be considered.

Laboratory experiments, important as they

*A paper presented before the Minnesota State Sanitary Conference, November 4, 1938.

may be, are by no means sufficient to demonstrate that a given disease is commonly transmitted by an insect in nature. Indeed, the results obtained may be sufficient to blind workers to the possibility of other, and more important methods of spread of the disease. The type of so-called experiment which consists merely of grinding up insects which have fed on diseased animals and injecting a suspension into healthy animals, *unless supported by other conclusive evidence,* proves no more than that the minute quantity of blood which the insect may have sucked up is infective. One ten thousandths of a c.c. of blood from an animal with South African horse sickness was shown by Theiler to be sufficient to infect a healthy horse. A fully fed mosquito may contain twenty times that amount.

The studies on the method of spread of yellow fever will long remain the outstanding illustration of the development of our knowledge regarding the insect transmission of a virus disease. As far back as 1853 the French physician, Louis Daniel Beauperthuy, though believing in the telluric origin of the disease, argued in the most explicit manner that it was transmitted by mosquitoes. Thirty-eight years later, Carlos Finlay postulated the existence of "something tangible, which requires to be conveyed from the sick to the healthy before the disease can be propagated" and reached the conclusion that the carrier of yellow fever was the mosquito known today as *Ædes ægypti.* We all know how brilliantly this work was supported and placed on a firm foundation by the American Army Commission. For more than a quarter of a century following, it was a dogma of preventive medicine that only through the agency of mosquitoes of this species could yellow fever be transmitted. Today we know that eighteen different species of mosquitoes are efficient transmitters of the virus under experimental conditions and that some of these, or others as yet unidentified, are responsible for transmitting in nature the yellow fever which lurks in the jungles. They are not only the close relatives of *Ædes ægypti* but include anopheline and culicine, as well as ædine mosquitoes. The latest reported addition to the group is *Ædes triseriatus,* a species occurring in this state and through the northeastern United States.

It must not be overlooked that Bauer (1928) demonstrated that the virus was able to penetrate the unbroken skin of a macacus monkey. In several instances in recent years investigators have contracted the disease in the course of autopsies or of laboratory work with the virus, in the absence of infective mosquitoes.

Following quickly after the work of the Army Commission came Graham's conclusive demonstration that dengue, or "break-bone" fever, is mosquito borne. Later investigations showed that, as in the case of yellow fever, the patient was infective to the insect only during the first three or four days of the disease and that there must be an incubation period of at least eight days before the mosquito could transmit it. Graham thought that it was carried by *Culex quinquefasciatus* but later workers have considered that he was using, at least in part, the *Ædes ægypti.* In all of the subsequent work this species or its very near relative in Asia, *Ædes albopictus,* have been shown to be primarily implicated in the spread of the disease. The trend of the present-day investigations of yellow fever should warn us not to make dogmatic statements regarding other suggested vectors.

In the meantime, Theiler and various other workers turned their attention to the possibility of the dreaded South African horse sickness being transmitted by insects. Pitchford (1903), claimed that he had transmitted it by allowing Anopheles and *Ædes ægypti* to feed on healthy horses forty-eight hours after feeding on diseased animals. Rickmann (1911), and subsequent workers have not been able to confirm this, although it has been widely credited by field workers. Other investigators have reported direct transfer by the bites of stableflies (*Stomoxys calcitrans*), horseflies (Tabanus spp.), "punkies" (Culicoides spp.), and hornflies (Hæmatobia). The question has not yet been settled definitely, despite thirty-five years of intensive study.

In view of the successes which had rewarded the search for insect vectors of various diseases, virus and others, it was inevitable that attention should be directed towards such a transmitter of poliomyelitis. C. W. Howard and Clark (1912) early presented the results of studies on this phase of the problem. They dealt especially with the housefly, bedbug, head and body lice, and mosquitoes. Lice and mosquitoes were found not to take up or maintain the virus but the bedbug took it from infected monkeys and could maintain it in a living state within the body, up to seven days. The housefly was shown

to carry the virus for several days on the surface of its body.

In 1912, Rosenau and Brues announced that they had demonstrated experimentally that the disease could be transmitted from infected to healthy monkeys by the bite of the stablefly, *Stomoxys calcitrans*. Anderson and Frost, of the Public Health Service, very soon announced that they had conclusively confirmed this work and much publicity was given to the results. During the epidemics in New York State and Pennsylvania in 1913-1914, full page headlines in daily newspapers warned the public of the necessity of avoiding and destroying the stablefly.

This work has been criticized on the grounds that sufficient precautions to prevent the accidental transfer of saliva and other possible infectious material had not been taken and more rigid experiments were so uniformly negative that the theory is given little credence today. Several workers have suggested that rat fleas may be vectors under natural conditions but there is no experimental evidence to support this hypothesis and it is generally believed by investigators that poliomyelitis is usually transmitted by contact with carriers or with those patently diseased. The possibility of insects being implicated under some conditions is by no means excluded.

Still fresh in the minds of even the layman is the St. Louis epidemic of meningo-encephalitis, in 1933. According to Bredick, there were 1,065 cases with 197 deaths, or twenty per cent, up to the tenth of October. City, state and federal agencies united in an intensive study of methods of spread of the infection.

The distribution of the cases was such that water, milk and food were early excluded and control measures were based on the belief that it was a virus disease transmitted through nasal secretions. Nevertheless, very serious attention was given to the theory that it was mosquito borne for, paradoxical as it seems at first thought, the worst drought in the history of St. Louis County had resulted in a veritable plague of mosquitoes. The explanation was that the numerous small rivers and streams of the region nearly dried up and not only created unusually favorable pools and sluggish currents, but reduced the natural enemies of the insects. The investigation of the possible rôle of mosquitoes in transmission was further stimulated by the results already obtained in experimental studies of equine encephalomyelitis.

All attempts to implicate mosquitoes, stableflies, houseflies, fleas or other blood-sucking insects were negative.* It cannot be claimed that the conclusions were final but there is little reason to suppose that arthropod transmission plays a significant, if any, rôle in the spread of meningo-encephalitis in man.

When it comes to the problem of equine encephalomyelitis there is tangible evidence that mosquitoes and, possibly, other arthropods, must be considered as incubators and potential carriers of the infection. This evidence we shall review briefly and then consider more particularly the local situation as regards possible vectors and their control.

Haring, Howarth and Meyer (1931), the first to definitely describe the disease, mention the possibility of its being spread by insects, and Meyer (1932), noting that the virus circulates in the blood, says: "Hence the rôle of biting insects deserves consideration." He also, at this early date, mentions three suspected cases in men handling infected horses but did not have available brain tissues for testing for the virus.

In connection with this pioneer work, Herms, Wheeler and Herms undertook studies of possible arthropod vectors. In a very carefully planned series of experiments they tested the hornfly, *Hæmatobia serrata* (= *Lyperosia irritans*), a horsefly, *Tabanus punctifer*, the stablefly, *Stomoxys calcitrans*, and two species of common mosquitoes, *Ædes dorsalis* and *Anopheles maculipennis*. Only negative results were obtained.

Except for the work with mosquitoes, the tests by Herms, Wheeler and Herms were conducted in 1932, though not published before October, 1934. In the meantime Kelser, in 1933, had announced that he had succeeded in transmitting the virus of equine encephalomyelitis from an inoculated guinea pig to a horse by the bites of *Ædes ægypti*. Mosquitoes fed on the horse during the period of high temperature and subsequently fed on a normal animal likewise produced the disease. The mosquitoes were infectious as early as the sixth day after feeding on the diseased animal.

An important contribution by Giltner and Shahan (1933) showed that there were two strains

*The epidemiological study of St. Louis encephalitis by Casey and Broun (*Science*, November 11, 1938) concludes that "Every known feature of its epidemiology is common to mosquito borne diseases." Experimental evidence is not educed.

of the virus, a western and an eastern one, which were serologically and immunologically distinct. The eastern type is much the more virulent and is rather narrowly limited, but the western type has spread eastward.

In 1934 Merrill, Lacaillade and Ten Broeck reported that both strains were transmissible by the salt marsh mosquito, *Ædes sollicitans,* and the western strain by *Ædes cantator.* Ten Broeck and his associates followed this with a series of papers in which they presented critical data relative to the period of infectivity of the horse and the multiplication and persistence of the virus within the insect host, and Madsen and Knowlton (1935), working in Utah, demonstrated that two species of native mosquitoes, *Ædes nigromaculis* and *Ædes dorsalis* were capable of transmitting the western type of virus from infected to healthy mosquitoes.

Of special interest to residents of Minnesota is the fact that Kelser, in 1935, was able to infect one of three guinea pigs by bites of *Ædes vexans.* Unfortunately, this work was interrupted by removal to Panama, where experiments were continued with another species, *Ædes tæniorhynchus,* which proved capable of transmitting the western, but probably not the eastern, strain of the virus. A single mosquito biting a normal guinea pig but once, produced encephalomyelitis and death of the pig in five days.

In the meantime Simmons, Reynolds and Cornell (1936) reported successful transmission to guinea pigs of the western type virus by *Ædes albopictus,* an Asiatic species closely related to *Ædes ægypti.*

To date, then, we have proof that at least eight species of Ædine mosquitoes are able to take up, incubate, and convey, under laboratory conditions, the virus of equine encephalomyelitis. These are *Ædes ægypti* ("Stegomyia"), *A. albopictus, A. cantator, A. dorsalis, A. nigromaculis, A. sollicitans, A. tæniorhynchus* and *Ædes vexans.* That several of these play an important rôle in nature cannot be doubted, although it is far from established that mosquito transmission is the only, or even the most important method of spread of encephalomyelitis to animals or to man.

Of the eight species listed, *Ædes vexans, Ædes dorsalis* and *Ædes nigromaculis* occur commonly in Minnesota. Overwhelmingly dominant in most parts of the state is *Ædes vexans,* a marsh-breeding species, which is noted for its migratory habits. In the course of studies aided by WPA on the pest mosquito problem of the Minneapolis-Metropolitan Area this past spring and summer, we found 98.28 per cent of the 337,960 mosquitoes trapped and identified were of this species. *Ædes dorsalis* was represented only to the extent of 0.26 of one per cent and *Ædes nigromaculis* by 0.01 of one per cent. These figures would vary, dependent on local conditions, but the great dominance of *vexans* remains as great in the regions where the three species are common.

Ædes vexans is known to deposit its eggs in low-lying ground where they may lie dormant not only for the remainder of the year but even for several years, until heavy rains create temporary pools which persist until the developmental cycle is completed. In warm weather this period may be as brief as four or five days. On emergence, the adults readily migrate for a distance of fifteen miles or more.

The vast areas of low-lying ground suitable for breeding places but not readily identifiable as such until there come periods of excessive rains, the value of the marsh hay and other crops of such areas, the expense of extensive drainage operations and the conflicting interests of various groups, make the problem of control of this and related species a difficult one which cannot be considered in detail at this time. In our urban areas a considerable reduction of pest mosquitoes will result from normal growth and from careful consideration of the problem in connection with planning for parks, lakes and streams, reservoirs and similar developments.

To the present no mention has been made of other possible vectors of the disease, though many insects have been submitted to us with the inquiry as to whether they are of importance in this respect. Some of them such as plant feeding leaf-hoppers, or spittle insects, could be immediately dismissed because of their habits and their distribution. Horseflies cannot be regarded as unworthy of consideration. They have been shown definitely to be direct carriers of anthrax and of several protozoal infections, but there is no experimental evidence incriminating them in the case of encephalomyelitis.

Some species of Simulium flies, commonly known as buffalo gnats, turkey gnats, or blackflies, are vicious blood suckers and there are notable instances of their attacks resulting in the

death of large numbers of horses, mules, cattle and hogs in the Mississippi Valley. Whenever they are abundant, many young chickens and turkeys succumb to their attacks. In spite of numerous suggestions that the deaths of these various animals are due to a virus transmitted by the Simulium, the whole picture is such as to support the view that the fatalities are due to the poisonous saliva injected by enormous hordes of attacking insects. The distribution of the species attacking horses does not in anywise correspond with the geographic distribution or observed characteristics of the spread of equine encephalomyelitis.

In view of the ease with which the infection is transferred experimentally by nasal secretions, one cannot entirely rule out the possibility of mechanical carriage by houseflies, stableflies and similar insects, but if it occurs, it must be exceptional.

Syverton and Berry (1936) report the transmission of the western strain of the virus to Richardson's ground squirrel by ticks which had engorged as nymphs for forty-eight hours on infected guinea pigs. The evidence is altogether too scant to justify drawing conclusions from these results but they raise anew the question as to whether there is a reservoir host which maintains the virus in nature. Certainly this transmission cannot account for the spread of the disease in a more direct manner.

By way of summary, it may be said:

1. That the epidemiological evidence indicates that arthropod vectors play a rôle in the spread of encephalomyelitis to animals and to man.

2. Mosquitoes of the genus *Ædes* most nearly meet the requirements for this transmission and there is conclusive experimental evidence that they are capable of taking up, incubating and increasing the virus, and then transmitting it to healthy laboratory animals and to horses.

3. There is no satisfactory evidence that other arthropods are implicated, unless under very exceptional conditions.

Difficulties in the way of accepting the theory that ædine mosquitoes are the most important carriers are:

1. In spite of numerous attempts, infective mosquitoes have never been found under natural conditions.

2. Our native ædine mosquitoes, and specifically, those shown to be potential carriers, do not winter as adults. Since diseased horses are infective to mosquitoes only in the first few days, there must be some explanation of the survival of the infection over winter.

3. The possibility of ticks being effective transmitters under natural conditions is very remote.

4. The readiness with which the virus is transmitted by the nasal route suggests that in the case of encephalomyelitis as in that of poliomyelitis, there are important methods of spread, other than by arthropods, even though mosquito transfer is clearly possible.

INFLUENZA, RABIES, AND ENCEPHALITIS*

CARL M. EKLUND, M.D.
Epidemiologist, Division of Preventable Diseases,
Minnesota Department of Health
Minneapolis, Minnesota

DURING the past decade great advances have been made in the study of virus diseases. Quantitative methods of studying immunity and physical methods such as the use of the ultra centrifuge and ultra filtration have been introduced.

Growth of virus in tissue cultures and on the chorio-allantoic membranes of the developing chick is receiving much study and is used both for isolation and preparation of virus for vaccine. This latter point is of great interest. Vaccine used for immunization against virus diseases at present contains much foreign material, and growth of virus in tissue culture cuts this to a minimum.

During the past year the State Board of Health has been especially interested in three of the virus diseases: influenza, rabies and encephalitis.

*Read at the Minnesota State Sanitary Conference, November 4, 1938, Minneapolis, Minnesota.

Influenza

About a year ago an influenza research laboratory was established in the State Department of Health.

The history of influenza virus research is very recent.

In 1931, Shope reported isolation of a virus which, in conjunction with H. influenzæ, suis, has caused influenza in swine in the middle west each fall since 1918.

In 1933, Laidlaw, Smith, and Andrewes reported isolation of a virus from human cases of influenza by means of intranasal inoculation of ferrets. They showed it to be closely related to the swine influenza virus.

In 1934, Francis reported isolation of the same virus from human influenza patients in Philadelphia and Puerto Rico.

In 1936, human influenza virus was transmitted to man accidentally from a ferret and produced clinical influenza. Russian human volunteers were infected by the human influenza virus. Influenza virus has been isolated in Russia, Germany, Australia, Alaska, and various parts of the U. S. A.

Strains of virus, while very closely related, do show a difference. Many problems need study:

1. There is the question of the existence of different strains which is of great importance in the production of vaccines.
2. Not all influenza-like diseases yield, on study, an influenza virus, yet some resemble influenza so closely in every respect that it seems certain they must be due to a virus, which, however, may be different from the influenza virus now known.
3. Clinically, it would be desirable, if possible, to differentiate the members of the influenza group from which it is possible to isolate a virus, from the rest of the group. Careful clinical studies are needed in association with influenza virus studies.
4. The whole group of respiratory diseases, included under the term "cold" and upper respiratory infection, need study from virus standpoint.

Present studies here are limited to those carried on in institutions since it is possible to study the clinical side better in such surroundings.

Rabies

We have been free from rabies since 1931 with the exception of one case in 1933 in a dog imported from Texas. This year, since May 4, positive diagnosis of rabies has been made in 105 dogs and 2 cattle. One hundred and sixty-nine people who have been in contact with the animals have taken rabies vaccine, and of these, thirty-one are said to have been bitten or scratched. In the lay mind, rabies causes greater apprehension than any other disease, and because of this, treatment is often demanded where degree of exposure does not justify treatment. Before giving antirabic treatment, the physician should question the patient carefully as to the type of exposure and type of lesion and examine the patient for lesions through which saliva may have entered. Risk of serious reactions from rabies vaccine, while not great, should be borne in mind when considering the use of antirabic vaccine in cases where exposure is slight.

Although rabies is a disease long studied, problems in connection with the disease still require study:

1. The evidence of various strains and the question of various clinical forms of rabies in different outbreaks in dogs.
2. Incidence in various wild animals, and question of reservoir in wild animals.
3. Use of mice makes possible a study of immunity following the use of various types of vaccine, both in men and animals. Over 200 people have had rabies vaccine. Opportunity exists for study of immunity in them. A better vaccine is still desired, one which gives higher immunity and less reactions. It is hoped that it will be possible to study some of these problems here.

Encephalitis

During the past five years, great advances have been made in the study of encephalitis. Up to 1933 the diagnosis of encephalitis of the non-suppurative type was clinical and pathological. The history of encephalitis is quite recent.

In 1917, Economo reported clinical and pathological findings in cases of encephalitis occurring in Austria. The disease has been often named after him although epidemic or lethargic encephalitis is the usual name now used. In 1918 and 1919 and the early '20's, there was a

great deal of this type of encephalitis reported. The disease has tended to occur sporadically since this time. This type of encephalitis has its greatest incidence in winter and spring and affects the younger age groups, fifteen to forty-five years of age. The disease is of slow onset, with low fever. It has a protracted course and numerous sequelæ. Eye muscle paralyses are common. Mortality is uncertain because of the existence of mild or questionable cases but is probably about 20 per cent. At the time the disease first appeared there were reports of transmission to animals and that it was due to a filterable virus. No further work was done.

In Japan, epidemics of another type of encephalitis have been occurring since 1871. The greatest epidemic occurred in 1924. It has been called summer encephalitis, because it occurred when the hot months were drawing to a close. It is acute in onset and short in course. The cranial nerve paralyses, so common in the Economo type, are rare in this type. Mortality has been, however, 60 to 90 per cent in various epidemics. The incidence and mortality increased directly with age. Sequelæ were few. The Japanese suggested that Economo encephalitis be called Type A, and that this be called Type B.

In 1933, an outbreak of encephalitis occurred in Missouri in St. Louis County and City. Over one thousand cases were reported. It started in July and the peak of incidence of disease occurred in late August. It resembled the Japanese type closely in time of appearance, age incidence and clinical course. There was sudden onset with headache, nausea or vomiting, and a temperature of 104-105°. Then there was drowsiness which might proceed to coma, or instead there might be delirium or restlessness. There was usually a short course, and the mortality was about 20 per cent. The sequelæ were few. Neurological findings outside of stiff neck and positive Kernig were not striking. There may have been absent abdominal reflexes, positive Babinski, or changed tendon reflexes. Paralysis of cranial nerves was uncommon.

A virus was soon isolated by Muckenfuss, Armstrong, and McCordock, and shortly after by Webster at the Rockefeller Institute. Monkeys and mice were found susceptible. It was shown that protective antibodies were present against the virus in blood obtained from convalescents.

In 1937 a similar epidemic occurred in St. Louis, and the same virus was again isolated.

In 1934 and 1935 other epidemics occurred in Japan and a virus was isolated that was shown to be distinct from the St. Louis type.

Equine Encephalomyelitis

Western Strain.—In 1931, Meyer, Haring, and Howitt reported the discovery of a virus as the cause of an epizoötic of encephalomyelitis among horses and mules in the San Joaquin Valley of California during the summer of 1930.

In 1933 the disease appeared along the eastern seaboard. In this year, TenBroeck and Merrill, and Biltner and Shahan reported the isolation of an eastern strain of equine encephalomyelitis virus which, though similar to the western strain, differed serologically. The disease in horses was more acute and fatal and the virus appeared to be more virulent for laboratory animals than the human strain.

The viruses of equine encephalomyelitis differ immunologically from the viruses of lymphocytic chorio-meningitis, the St. Louis type of encephalitis, Borna disease, vesicular stomatitis and poliomyelitis.

Present epidemiological and experimental evidence points to spread by an insect vector and not by contact. Experimentally, mosquitoes can be infected and transmit the virus to laboratory animals and horses. A. ægypti, A. sollicitans, A. nigromaculis, A. dorsalis, A. albopictus Skuze, A. vexans, and A. tæniorhynchus, can transmit the western strain; A. cantator and A. sollicitans, the eastern strain. To date no one has found infected mosquitoes in localities where equine encephalomyelitis is prevalent.

Meyer, in 1932, suggested the possibility of human infection from the equine strain. He briefly reported three cases of encephalitis occurring in men closely associated with horses having encephalomyelitis. No virus was isolated or protective antibodies demonstrated.

Equine encephalomyelitis was very prevalent in Minnesota during the summer of 1937. During the last week of August and the first two weeks of September 1937, six cases of human encephalitis, all farmers, were reported from a county in Northwestern Minnesota. Five had had contact with sick horses. The sixth had had no contact with sick horses at the time of onset of his illness. He drove a tractor on a farm

in North Dakota not far from the Minnesota border. There was much equine encephalomyelitis in this locality.

Blood was collected from three of the recovered patients during January 1938. Dr. C. TenBroeck of the Rockefeller Institute demonstrated neutralization of the Western strain of equine encephalomyelitis virus by one of the sera. Blood was collected again in May 1938 from this patient and neutralization again demonstrated by Dr. TenBroeck. This was the patient who had had no contact with sick horses and had been sick about three weeks.

Four mosquitoes shown to transmit the western strain occur in Minnesota: A. vexans, A. nigromaculis, A. dorsalis, and A. tæniorhynchus. Of these only A. vexans is a common mosquito.

Eastern Strain.—In late August and early September 1938, equine encephalomyelitis invaded southwestern Massachusetts for the first time. At the same time a highly fatal encephalitis among children appeared. Only meager clinical reports have been made to date. Drs. Fothergill, Dingle, Farber, and Connerly at Harvard isolated the eastern type of equine encephalomyelitis virus from the brain of a patient. Drs. Webster and Wright at the Rockefeller Institute confirmed this, and in addition isolated the virus from the brains of four other patients. In addition, virus was sent to the Division of Animal Husbandry at Washington, D. C., and the above work was confirmed, using horses as experimental animals.

Summary

In summary, under the infectious non-suppurative type of encephalitis, the following known types of virus may be listed:

1. Economo or lethargic encephalitis, probably caused by virus.
2. Japanese type, virus isolated, protective bodies present against it in the serum of recovered patients.
3. St. Louis type, virus isolated, protective bodies present against it in the serum of recovered patients.
4. Encephalitis caused by eastern and western strains of equine encephalomyelitis virus, protective bodies present against them in the serum of recovered patients.

NOTE: After presentation of the above paper, isolation of the Western strain of virus from the brain of a twenty months old child was reported by Dr. B. F. Howitt of California.

EMERGENCY TREATMENT OF INJURIES*

H. M. LEE, M.D.
Minneapolis, Minnesota

THE susceptibility to injury is universal; there is no immunity. The treatment of the injured is chiefly the concern of the medical profession but not of the surgeon alone. This is especially true in smaller towns and rural communities. In the larger cities and industrial centers the major portion of the care of the injured has fallen to the general surgeon. In the last decade or two the industrial injuries at least have passed largely into the hands of the industrial surgeon. Even the laity must assume some responsibility in emergency treatment of injuries. It is not only frequent but almost the rule that some immediate care is rendered by laymen before skilled medical service is available. Many industrial plants and commercial institutions employ a lay person with some instruction in first aid. A nurse is frequently employed for this purpose. I am certain that the morbidity in accidental injuries has thereby been reduced. The public generally has been enlightened along many medical lines, but I believe that with such general and only superficial information as we can broadcast, the importance and necessity of skilled medical care for every type of injury should be stressed. It is often the apparently insignificant but neglected puncture wound which leads to disaster. In my short discussion, I shall make no attempt to describe detailed surgical procedures applicable to the endless number of specific injuries which we encounter. I shall attempt rather to review and discuss certain principles of treatment applicable to types of injury, surgical principles most of which are neither new nor original but which, like a prayer, may bear repetition. For the purpose of this paper, injuries may be classified roughly according to anatomic location such as:

*Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1938.

1. Head injuries
2. Injuries to chest and abdomen.
3. Injuries to the back.
4. Injuries to the extremities.

Injuries to the extremities are by far the most common and therefore of great importance, both from this and an economic standpoint. The symptoms and signs of injury requiring our immediate attention are: pain, hemorrhage, and shock.

Pain naturally varies in degree depending upon the severity and location of the injury, and the susceptibility of the individual to painful stimuli. There are certain portions of the body surface such as the lips, fingers, external genitalia, and the perianal region which are more richly innervated with pain fibers than are others. Likewise, there are some organs more sensitive to pain than others. For instance, bones give rise to pain more readily than do muscles. The sensitivity of the testis and blood vessels forms a tremendous contrast to the relative insensitivity of the fascia, cerebral cortex, and cartilage. The difference in susceptibility to pain in individuals is well recognized. Paralleling this phenomenon there is also the well known fact that there is a marked difference in susceptibility to drugs among individuals.[3]

Hemorrhage may be from the gaping margins of an open wound, into deep structures, or into closed cavities such as the cranial, thoracic, and abdominal. The natural processes which some into play to control and to arrest hemorrhage often do not suffice and then the surgeon must resort to artificial methods of controlling hemorrhage. Intravenous injections of calcium chloride or repeated small transfusions of whole blood may be indicated. At times, there may be troublesome bleeding from arteries which do not permit clamping or transfixing. In such a case a piece of fresh muscle rubbed on a piece of gauze and quickly applied will often promote clotting. Recognition of internal hemorrhage is often difficult. Here, the careful observation of blood pressure is of help. An increasing pulse rate should lead one to suspect bleeding. Pallor, anxiety, restlessness, and thirst are signs of continuing hemorrhage. Obviously, its control is urgent.

Shock is not always easy to differentiate from severe hemorrhage. In shock, however, the onset is usually abrupt. The patient is apathetic, but not unconscious. There is no restlessness or anxiety, but rather, indifference. The temperature is subnormal, and there, too, the blood pressure is low. The treatment is external heat, judicious use of morphine (except in head injuries), elevation of the foot of bed, and blood transfusions.

The emergency treatment of injuries then, generally speaking, resolves itself into: (1) the management of symptoms as they present themselves; and (2) to the more deliberate and planned treatment of the injury itself. This planned treatment must consist of careful examination of the injury by inspection, frequently palpation, demonstration of function or loss thereof, and x-ray examination. The importance of this step is obvious. Many wounds have been sutured leaving severed tendons or nerve trunks unrecognized beneath the sutured skin. Foreign bodies in the depth of the wound are frequently over-looked. Fractured bones may be left unreduced and unsplinted. The next logical step is directed toward the prevention of infection in the clean wound and to combat infection in the contaminated wound. The former is accomplished by strict attention to asepsis, such as the proper preparation of the surgeon's hands, the wearing of a mask covering nose and mouth, a surgeon's cap, and aseptic care of patient's skin surrounding wound. This last is accomplished by careful cleansing of the skin with soap and water,[8] great care being taken not to wash dirt into the open wound. This can be done by carefully covering the wound with sterile dressings, and when an extremity is involved it should be raised as the skin proximal to the wound is cleansed and lowered for the washing of the region distal to the wound. The clean wound is then swabbed with an antiseptic which will not damage the tissue cells by precipitating protein. For this purpose I prefer one of the newer organic mercurial germicides. The wound is then closed not too tightly, loose dressings applied, unless temporary pressure is required to control bleeding.

The contaminated or potentially infected wound must receive the best care the surgeon's skill and experience can muster. How frequently we have seen extensive crushing lacerated wounds tightly sutured and snugly bandaged without proper preparation, and consequent disaster. The proper treatment of such a wound,

after adequate examination, should consist in not only proper preparation of the surgeon as for a major operation but meticulous cleansing of the wound itself as well as the surrounding skin. This is accomplished again by thoroughly cleansing of the wound with neutral white soap and water or normal salt solution,[10] débridement of the devitalized skin and muscles, insertion of Carrel-Dakin tubes, and leaving the wound open or only partially closed, with loose dressings, immobilization, elevation, and irrigation every two hours with Dakin's solution.

Severed tendons and nerves should be sutured as early as possible. For this purpose, fine silk is recommended.[8] This applies at least to reasonably clean wounds or where there is a reasonable likelihood that the wound will heal without any severe infection. In contaminated wounds a secondary suture is advisable. A period of at least three weeks must elapse after the original wound is completely clean and healed. Suture of the extensor tendons on the dorsum of the hand to about the proximal phalanges offer the best prognosis.[11] Here, if the gap is not too great, union may occur even without suture. These tendons are free, isolated, and accessible. In the case of the middle phalanx of the fingers division of the tripartition of the extensor aponeurosis with its different insertion for each partition, causes a quite characteristic and prognostically very unfavorable injury. Injury to the flexor tendons of the hand and fingers offers a worse prognosis due to their ensheathed condition. In addition, the palm of the hand shows a structure very appropriate for the protection of sensitive structures, but very inappropriate surgically. Tendons should be sutured within six hours from time of injury if primary suture is done. The part should be immobilized for ten or twelve days in position to relieve tension, and splinted for three weeks. Essentially, the same rule applies to both severed tendons and nerves.

The treatment of localized infections and frankly infected wounds is not ordinarily considered emergency treatment, but frequently patients with such conditions do not seek any medical care until infection is well established. The treatment may depend somewhat on the location of the infection. In general, a spreading infection should be allowed to localize before any incision is made.[6] Infections about the face, mouth, and neck should be treated very conservatively. Blair has stated that he has never seen a fatality in such a case treated conservatively, that is, where the infection has not been pinched, punctured, or incised or otherwise tramatized. The treatment should consist of application of heat, ultra-violet rays, rest, and fluids. Sulfanilamide may be indicated. Infected wounds and spreading infections in other locations are also best treated by hot packs consisting of light moist dressings kept warm with a heat cradle or lamp, and elevation. The matter of hot packs is of some importance in its application. These are best applied as light moist dressings kept warm with a heat cradle, frequently moistening the dressings with sterile water, normal saline, or boric acid solution. Frequently, hot packs are applied in great bulk. These gradually cool and before long the wound is enveloped in a cold pack. The purpose of the hot pack is to produce active hyperemia and this is facilitated by elevation of the extremity to relieve the passive hyperemia.

Ochsner's solution, properly applied, is of definite therapeutic value in spreading infections with lymphangitis and induration.

X-ray treatment of infections is apparently of real benefit.[4] Koch[6] gives a half erythema dose and has found this to be of definite value.

Localized infections and tendon sheath infections require immediate incision and drainage. Hot packs, as described above, and elevation is indicated.

Recently, Wangensteen at the University of Minnesota, has described treatment of acute infections by rigid immobilization of the extremity in plaster-of-Paris casts holding the extremity in elevation. He has shown that this type of treatment is of definite value.

Burns, especially if at all extensive, are best treated by the so-called tannic acid treatment. This was introduced by Davison about twelve years ago. Bettman has recently modified this treatment to the extent of applying silver nitrate after the application of tannic acid.[5] The technic of this treatment consists, first of opening all blebs, removing all burned and necrotic tissue, cleansing the burned area of grease and dirt, then spraying the burned area with a freshly prepared 5 per cent aqueous solution of tannic acid and following this with application of 10 per cent silver nitrate with cotton pledgets. The patient is then placed on a sterile sheet and a

heat cradle applied over the body. For small burns, I personally prefer nupercainal ointment. This relieves pain promptly, dressings do not stick to the wound, no heavy crusts form, and the wound is easily kept clean.

The emergency treatment of chest and abdominal injuries is an extensive subject in itself and will be discussed only briefly. (A recent article by Karl Meyer is made free use of.) Practically all penetrating wounds of the abdomen should be explored as soon as possible, taking into consideration, of course, the patient's general condition. Hemorrhage and shock must be treated first unless it is apparent that there is rapid and extensive internal hemorrhage which only immediate operation can control. Perforations of the bowel and stomach produced by stab or bullet wounds are closed. The most rapid method of accomplishing this is to make a long paramedian incision and at once eviscerate the intestines into warm wet towels. Small to moderate sized wounds of the liver are best sutured with catgut through pieces of muscle excised from the abdominal wall. Muscle may also be inserted into the wound cleft.

Both surfaces of the liver must be repaired. Large wounds of the liver must be tamponed with gauze, left as a drain, and a snug bandage applied about the abdomen for pressure.[7] Such abdominal wounds are not drained; only the abdominal wall. Wounds of the spleen of any degree are best treated by splenectomy. Wounds of the pancreas are sutured or tamponed and drained. In suspected rupture of the urinary bladder Butler recommends, if the urine contains blood or if no urine is obtained by catheter, the injection of 500 c.c. of 5 per cent sodium iodide solution and x-ray to make a positive diagnosis.[1] Wounds of the urinary bladder are closed with catgut in two layers and the bladder kept empty by means of a retained catheter for six or seven days.

In injuries of the chest it should be kept in mind that half of the ribs cover the abdomen so that penetrating wounds below the fifth rib must lead one to suspect injury to abdominal viscera. The usual policy in penetrating wounds of the lungs is conservative management.

Head injuries may vary from minor lacerations of the scalp to extensive skull fractures with varying degrees of brain injury. Severe head injuries must be treated by bed rest, external heat, intravenous administration of 50 to 150 c.c. of dextrose solution, probably lumbar puncture and drainage reducing the pressure 50 per cent and limitation of fluids.[2]

Craig advises against the use of morphine in severe head injuries.[2] He recommends the use of barbiturates. Sodium amytal intravenously may be given for quieting. The closest observation is indicated. I am omitting from my paper any discussion of back injuries and fractures.

Summary

1. Some general knowledge of first aid treatment of injuries on the part of the public is important.

2. All injuries should receive the most careful care in regard to general cleanliness and asepsis.

3. Skilled surgical care is indicated in all types of injuries.

4. Experience and judgment are important qualifications in determining the type of treatment indicated in infected wounds.

5. Immobilization, elevation, and heat are important therapeutic measures in treating injuries and infections.

Discussion

Dr. Benjamin F. Davis, Duluth: Amidst the avalanche of advice as to what to do, especially in certain classes of industrial emergencies, basic principles of surgery are frequently lost sight of. The demand to *do* something is so great that many times a something is done just because it is the fad of the moment, or worked out well in a previous case, regardless of the indications which a proper analysis of the particular case to be treated would show.

Consider the matter of wound infections. The arguments as to the type of disinfectant, if any, to be used, the type of drainage to be employed, how to apply hot moist dressings and so on are beside the point and of minor importance. The question is, how long an interval has elapsed since this wound was in-

flicted, what is the character of the wound and what is the degree of contamination? Wounds seen within twelve to twenty-four hours of their infliction are in the stage of contamination. The bacteria are on the surface and careful mechanical cleansing of the wound with removal of devitalized tissue very frequently will permit of primary closure and primary union. Wounds seen in the next twelve to twenty-four hours will be in the stage of invasion. Bacteria may have penetrated beneath the surface cells and have been carried into the deepest recesses, and mechanical cleansing, other than complete debridement, may not suffice to remove all such organisms but probably will greatly minimize the degree of subsequent wound infection. Wounds seen after forty-eight to seventy-two hours, will almost certainly be in the stage of established infection. Mechanical cleansing will accomplish little, but adequate drainage, if infection is established, is essential.

The immobilization of infected wounds either by splints or casts is of prime importance and the essayist is to be commended for emphasizing a point which is too often forgotten.

Consider, now, the matter of head injuries, particularly when associated with loss of consciousness. Here, more than in any other field of industrial surgery, the temptation to fit the patient into some special form of treatment rather than to make the treatment fit the patient seems to be well nigh irresistible. Each case of head injury, with loss of consciousness, must be individualized. Frequent observations on the condition of the pulse, the respiration, the rectal temperature and the state of consciousness should be made. In the majority of instances, it will be possible, by this means alone, to estimate the danger of mounting intracranial pressure fairly accurately and to determine when surgical decompression becomes necessary and when less radical measures may suffice. I can best illustrate this idea by the means of two case histories:

Case 1.—This patient fell while in an alcoholic state, and struck his head against a curbstone. He was unconscious for five minutes, but on admission to the hospital his state of consciousness was good, his respiration normal, his temperature by mouth 99.6° F., and his pulse 60. He was discharged on the eighth day after his accident, "feeling fine except for slight headache," with his state of consciousness good, his respiration and temperature normal and his pulse 56. The following morning, however, this patient returned to the hospital, complaining of severe headache and vomiting. His state of consciousness, respiration and temperature were as before, and his pulse rate was 60. After thirty-six hours of rest in bed, the pulse rose to the seventies and the headache and vomiting ceased. This was a case of head injury with concussion, a moderate increase of intracranial pressure, well compensated (note the moderate bradycardia), and required no complicated or radical treatment.

Case 2.—This patient had had a mild headache for one week. Immediately after making a sudden effort, she clasped her hands to her head and complained of a sudden, severe headache. This was immediately followed by a clonic convulsion and unconsciousness. On admission to the hospital, the patient had regained consciousness; her temperature was 97.4° F., her respiration 29, her pulse 64. The spinal fluid was bloody. The patient became drowsy and gradually stuporous, as the pulse dropped to 48 and the respiration to 10. Breathing became of the Cheyne-Stokes type. This condition persisted for approximately 24 hours, when, without other change, the temperature rose to 100, the pulse to 140 and the patient died. Autopsy disclosed hemorrhage from a ruptured aneurysm of the right middle meningeal artery. This was a case in increasing intracranial pressure finally extending beyond the limits of physiologic compensation; the physiologic signs demanded radical treatment, but were disregarded.

I believe that each of these cases is typical of a certain group of head injuries and that in each the clinical story is clearly told by the obvious physiologic changes, which also clearly indicate the treatment demanded.

I am not taking issue with the essayist on any of the points which he has raised in his excellent paper. It is my purpose to stress the necessity for properly analyzing and diagnosing the conditions to be met and making the treatment fit the patient rather than to rely on stereotyped formulæ.

ABDOMINAL INJURIES*

E. MENDELSSOHN JONES, M.D.
Saint Paul, Minnesota

ABDOMINAL injuries caused by penetrating wounds or by contusion of the abdomen with resulting visceral damage are accompanied by a high mortality. In 1890 the mortality rate was about 90 per cent. This figure has gradually dropped until at present the rate for this type of injury throughout the United States is approximately 50 per cent. These patients are most frequently seen in industrial hospitals and in the large city hospitals. A group of seventy-one cases treated at Ancker Hospital in St. Paul were reviewed. This hospital has a large and very active emergency service. Despite the fact that these patients are given immediate treatment and kept under constant observation it is startling to learn the high mortality encountered. What is the reason for this high mortality in an institution adequately equipped to care for such cases?

This group includes thirty-two patients who had received penetrating abdominal wounds, and thirty-nine patients who had abdominal contusions accompanied by visceral injury.

Twenty-eight of the patients with penetrating wounds were operated upon, four having been so badly injured that there was no possibility of giving any surgical relief. Fifteen of this group recovered and seventeen died, a mortality of about

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1938.

TABLE I. ABDOMINAL INJURIES

Total number of cases	71
A. Penetrating wounds with visceral injury	32
Cases operated upon	28
Recovered	15
Died	17
Mortality	53.2%
B. Contused wounds with visceral injury	39
Cases operated upon	14
Recovered	7
Died after operation	7
Died without operation	25
Mortality	82.1%

TABLE II. PENETRATING WOUNDS

Gun shot wounds	27
Stab wounds	5
Cases operated upon	28
Not operated upon	4

Cases not operated upon, all gun shot wounds:

1. Died three hours after admission. Perforation of mesentery and kidney. Severe hemorrhage.
2. Died two hours after admission. Perforation of colon and jejunum. Severe hemorrhage.
3. Died seven hours after admission. Severe wounds of abdomen, chest and head.
4. Died four days after admission. Injury to lung, spleen, stomach, colon and small intestine.

TABLE III. PENETRATING WOUNDS OPERATION DEATHS

Died within six hours	4
Died within twelve hours	3
Died within twenty-four hours	3
Died after forty-eight hours	7
Died following operation	13

This group of patients had the following injuries:

Liver and duodenum	1
Small intestine	1
Small intestine and colon	3
Pancreas, duodenum and liver	1
Small intestine, iliac vein, severe hemorrhage	2
Stomach and small intestine	1
Colon	1
Small intestine and kidney	1
Liver and stomach	1
Colon and spleen	

TABLE IV. PENETRATING WOUNDS. OPERATION RECOVERIES

Cases operated with recovery

Injuries to liver	3
Small intestine, spleen—spleenectomy	1
Small intestine	6
Colon and small intestine	1
Spleen and kidney—splenectomy	2
Stomach and duodenum	1
Stomach and transverse colon	1

53.2 per cent. A brief analysis of this group is shown in Tables I to IV.

It is interesting to note that the highest number of recoveries occurred in the patients in this group in whom the small intestine was the only abdominal viscus injured, and that only one of these died. Furthermore, all but two who died had two or more structures injured, increasing the gravity of the problem and partially explaining the high mortality rate.

TABLE V. CONTUSED WOUNDS OF THE ABDOMEN WITH VISCERAL INJURY

Seven patients recovered. All operated upon. This group had the following injuries:

Rupture of liver	1
Rupture of bladder	2
Rupture of small intestine	3
Rupture of spleen, splenectomy	1

Seven patients died following operation:

Died within six hours	3
Died within twelve hours	1
Died within twenty-four hours	1
Died after forty-eight hours	2

TABLE VI. CONTUSED WOUNDS. INJURIES FOUND IN PATIENTS WHO DIED AFTER OPERATION

Rupture of liver	2
Rupture of spleen, splenectomy	3
Stomach, small intestine and colon	1
Ruptured bladder	1
Died without operation	25
Died within six hours	15
Died within twelve hours	2
Died within twenty-four hours	3
Died within forty-eight hours	5

TABLE VII. CONTUSED WOUNDS. INJURIES FOUND IN NON-OPERATION DEATHS

Ruptured liver	11
Ruptured liver and spleen	3
Ruptured spleen	2
Rupture of small intestine and colon	1
Rupture of small intestine	2
Ruptured bladder	2
Rupture of kidney, spleen and liver	1
Rupture of kidney and liver	1
Retroperitoneal hemorrhage	1

Fourteen patients in this group had one or more complicating fractures.

There were thirty-nine cases of contusion of the abdomen with visceral injury (Tables V to VII). Fourteen of these patients were operated upon with seven recoveries. Twenty-five died without operation and of this group fifteen died within six hours after admission. There were severe liver injuries in eleven instances in the non-operated group. Fourteen of these patients sustained one or more fractures in addition to the abdominal injury, again contributing to the appalling mortality rate. There is no question that many of the injuries we are called upon to treat today are more complicated and severe than those encountered before the advent of the high-speed motor car and the speed mania that has spread

over the country. Many of the automobile injuries are of the crushing type and there is often injury to the liver or spleen with or without injury to any other abdominal viscus. In this group of thirty-nine cases there was either a liver or a spleen injury alone or combined in twenty-six instances. This fact in itself explains a great deal of the high mortality rate in this group.

There are no cases included in this series of simple contusion or concussion of the abdomen. In this type of injury the patient is "knocked out" for a few minutes and recovery is prompt. However, in the more severe cases the picture is more complicated, presenting marked pallor, anxious expression, severe pain in the abdomen, labored, shallow respiration, thin, rapid pulse, low blood pressure, subnormal temperature, and frequently nausea and vomiting. Usually patients with simple contusion recover in a few hours from the state of shock. The picture of shock in these cases is similar to that found when visceral injury is present and it frequently is three or four hours before a positive diagnosis can be made. The shock is likely to be less profound and the recovery is usually more rapid. Because of the difficulty in differentiation, an occasional unnecessary abdominal exploration is carried out.

When there is contusion of the abdomen with visceral injury, the primary shock above described is present and with proper shock treatment, recovery occurs in three to four hours. At this point it is necessary to determine, if possible, the extent of the visceral injury. Very close observation of the patient is absolutely essential and every clinical sign must be carefully observed. In this way the early warning signs following the initial improvement will be detected. An increase in the pulse rate with a decrease in its volume is found in cases of marked hemorrhage. Muscular rigidity is frequently present and tenderness over the injured area may often be found. In injuries to the spleen a severe pain in the left shoulder, with painful respiration and restricted diaphragmatic movement on the left confirmed by x-ray, is of valuable diagnostic importance. If, after careful analysis of all the findings, it is determined that there is severe intra-abdominal bleeding, immediate exploration should be done. However, should the symptoms not indicate a severe hemorrhage there is no immediate operative emergency to deal with and expectant treatment may be followed.

One must, however, bear in mind that in spleen injuries there may be a delayed hemorrhage necessitating surgical treatment. A recent example of this was a young man who was playing basketball and was struck in the abdomen by the head of an opponent. He was able to finish the game but did not feel right. He consulted his physician and was allowed to return to work the next day. About ten days after the injury he was admitted to the Ancker Hospital. He presented the picture of severe intra-abdominal bleeding. His abdomen was explored and a spleen that weighed 760 grams was found fractured. The abdomen contained a great quantity of blood. A splenectomy was done. He developed post-operative pneumonia and after this subsided he was apparently making a good recovery. However, he again began running a high fever and a cause for the temperature was not found. He died about thirty days after admission. On autopsy many ulcerations were found in the intestines and eventually a diagnosis of typhoid fever was made. During the search for the cause of his temperature, a Widal test was made and reported negative.

It is very important to obtain an accurate history to determine if possible the degree of force and the direction of its application. When there is evidence of rupture of a hollow viscus, exploration must be performed as soon as the condition of the patient will permit. It has been shown that under these circumstances the mortality mounts greatly if this is not done within six hours after the injury.

The x-ray is a great aid in making a diagnosis of bowel or stomach perforation as free gas can often be observed under the diaphragm. Examination should be made with the patient in an erect position if possible, but if the patient is too ill he should lie on the right side, as a small amount of gas is more easily detected on the left side. Each case presents a different clinical problem and calls for the keenest clinical analysis by the surgeon. It is conceded that various clinical and laboratory methods are important but they do not replace keen clinical sense and interpretation. A recent experience was that of a man working with a motor-driven circular saw. A small piece of wood about four inches long and an inch wide flew from the saw and struck him in the abdomen. He had severe abdominal pain and was taken to a physician. The incident was treated light-

ly and he was sent home. His employer was not satisfied and wished further investigation. The patient, when admitted to the hospital, was having severe abdominal pain and had slight tenderness over the mid-abdomen. X-ray examination showed no free gas in the abdomen. In spite of this an exploration was done immediately and a laceration was found in the jejunum. This was sutured and the patient made a prompt recovery.

Injuries to the urinary bladder are frequently encountered, especially so in association with a fracture of the pelvis, and the repair should be done as soon as possible. Crushing injuries to the kidney are also common but do not often call for an emergency procedure as the injury is retroperitoneal and the compactness of the structure in this area aids in controlling the hemorrhage. An x-ray picture will sometimes show gas around the kidney and thus indicate rupture of the retroperitoneal portion of the duodenum or retroperitoneal portion of the colon.

Injuries to the gallbladder and bile ducts are not frequently encountered, but when present they must be cared for surgically. In pancreatic injury there may be a complete tear which sets free the pancreatic secretions, and pancreatic digestion and necrosis follow. Unless this damage is repaired and drainage established, the injury is usually fatal. There may be a less severe injury to the pancreas, resulting in the formation of a pancreatic cyst. Not infrequently mesenteric tears occur, resulting in severe hemorrhage demanding early surgical relief. Diaphragmatic hernia is another condition that must be considered in connection with contusion injuries to the abdomen. In a person receiving a severe blow to the abdomen a hernia through one of the diaphragmatic openings, usually the esophageal, may develop. When the abdominal injury is accompanied by a chest injury, there may be a rupture of the right or left hemi-diaphragm.

Bullet wounds or stab wounds of the abdomen may not injure any of the viscera, but if there is a perforating injury to a solid viscus, hemorrhage results, and peritonitis develops if there is perforation of a hollow viscus. Gunshot wounds are prone to give rise to tetanus, gas bacillus and other infections not only of the peritoneal cavity but of the abdominal wall. Unless one is positive that the wound has just grazed the abdominal wall without entering the peritoneal cavity, the abdomen should be explored immediately. Bullet wounds may cause many perforations of the intestines and all the perforations must be closed. It has often been pointed out that in this type of injury there is an even number of perforations, and this is a valuable point to keep in mind. These openings are often very difficult to find. In discussing this point with Dr. John Noble, Pathologist at the Ancker Hospital, he commented on the number of cases that he has seen come to the autopsy table that have died of peritonitis because one intestinal perforation had been overlooked.

I realize the mortality rate of 53.2 per cent in the cases with penetrating abdominal injuries seems high, but it corresponds to other reports for similar cases. As pointed out previously, the highest number of recoveries occurred in the cases receiving only small bowel injury. The high mortality rate of 82.1 per cent in the group of contusions with visceral injury is explained by the severity of the abdominal injuries and also by the other severe injuries frequently sustained.

Summary

1. Abdominal injury complicated by visceral damage is accompanied by a high mortality.

2. Constant observation of these cases is necessary until the extent of the injury is determined.

3. The treatment of shock is the first consideration in cases of abdominal injury.

4. Abdominal exploration should be carried out as soon as possible in cases of severe intra-abdominal hemorrhage and in penetrating wounds of the abdomen.

Discussion

Dr. Wm. C. Bernstein: It has been a pleasure for me to listen to Dr. Jones' very clear and frank discussion of abdominal injuries. Drawing on my limited experience, compared to his, it would be difficult for me to add much of consequence to his paper. However, I would like to discuss several points.

Practicing as I do in rural Southern Minnesota, I am often impressed with the large number of these major abdominal injuries which occur outside the industrial centers. Farm implements and farm animals account for a large number of these accidents but the ever increasing automobile hazard on the highways where strict traffic regulations are not enforced as they are in the cities furnish a great many cases of abdominal injuries. Gun-shot wounds of the abdomen during the hunting season are also becoming quite common. For this reason most small hospitals in rural Minnesota have become equipped to handle these cases as well as they are handled in any larger center. I say this without fear of contradiction.

Dr. Jones has stressed the point that close and undivided attention must be given to these patients during the first hours to determine whether the shock is due to the so-called "abdominal concussion" or to actual visceral damage. This brings up the question of blood transfusion in these cases. So often, we hear of large amounts of blood or other fluids being given to a patient for his hemorrhage where, in fact, the fluid is running out of his torn vessel as fast as it is being introduced into the vein. Many patients would be better benefited if the abdomen were opened, the bleeding vessels tied off, and the introduction of blood or other fluids then started. We must not forget that raising the blood pressure can easily start a vessel bleeding once more.

Finally, I would like to emphasize the point that many a patient's life has been saved by the good judgment of the surgeon in deferring operation. This is especially true in cases of retroperitoneal injury, including rupture of the kidney. Dr. Jones has mentioned the fact that due to the compactness of the structures, hemorrhage here often takes care of itself. I recall one case in point where a man had a ruptured kidney and was brought in in extreme shock. There is no question but what he would have died if we had operated on him. We treated him expectantly and when he was in good shape for operation he refused and has now worked hard for five years without an operation.

INTRACTABLE LOW BACK AND SCIATIC PAIN DUE TO PROTRUDED INTERVERTEBRAL DISKS: DIAGNOSIS AND TREATMENT*

J. GRAFTON LOVE, M.D.
Rochester, Minnesota

THE intervertebral disks act as shock absorbers; they probably were the first hydraulic shock absorbers invented. When one of these disks becomes injured and a portion of it protrudes, the patient may complain of backache or sciatic pain. For years, such patients have received the most varied treatment. The treatment in many cases has run the gamut of pharmacologic, orthopedic and physical therapeutic measures. Manipulations and adjustments by irregular practitioners likewise have been given credit for the relief and, in some cases, even for semimiraculous cures of some of these partially or wholly disabled individuals.

The more or less general use of roentgenography in studying the vertebral columns and sacro-iliac synchondroses of individuals whose chief complaints were backache and sciatica did much to clarify thinking concerning painful conditions of the spinal column. The condition known in the earlier literature as "railway spine" practically disappeared. Physicians and even laymen began to feel that if roentgenograms of the vertebral column gave evidence of a normal condition and no evidence of fracture, there could be no gross change in the skeleton to account for the pains in the back and legs. During the past few years tremendous progress has been made in diagnosis and treatment of many heretofore obscure painful conditions.

It is not my desire to increase the number of already alarmingly high industrial hazards nor to cause men and women to seek compensation that is not their just dessert. It is my desire only to call attention once again to a very common cause of partial or complete chronic invalidism. This cause is notorious for the paucity of objective findings in the course of the usual physical examination. Ordinary roentgenography, likewise, fails in the vast majority of cases to give a clue to the real pathologic condition which underlies the patient's disability.

Although lesions of the intervertebral disks as a cause of intractable sciatic pain have been recognized for many years and Adson, at The Mayo Clinic, in 1922, cured a dentist of intractable sciatica by removing a protrusion of a lumbar disk, it has only been within the last few years that a more general appreciation of the rôle of the intervertebral disks in the causation of compression of the spinal cord and nerve roots, with subsequent development of painful syndromes, has come about.[5]

Prior to the realization of the frequency with which intervertebral disks may be protruded and

*From the Section on Neurologic Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29 to July 1, 1938.

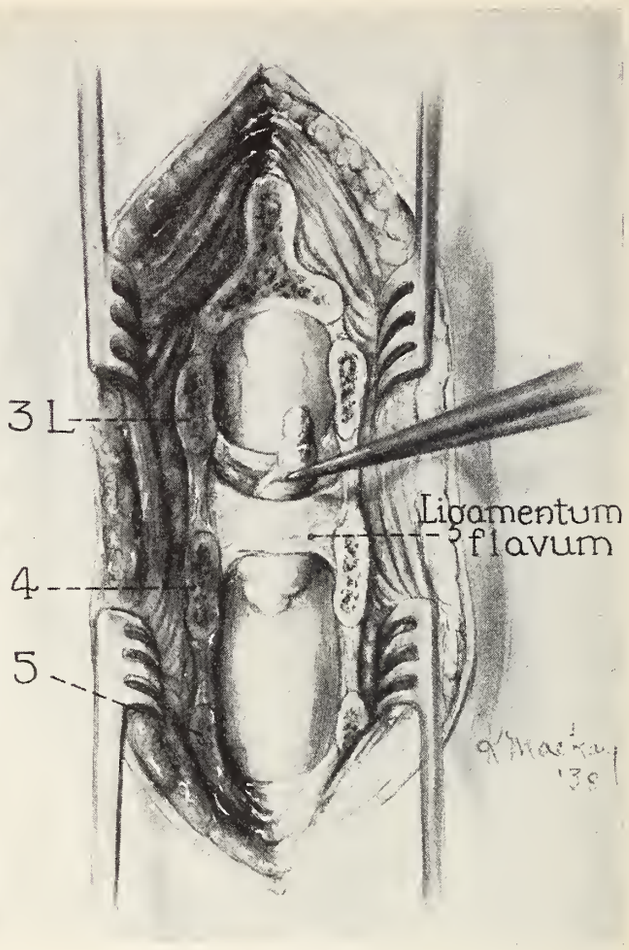
be the cause of low back and sciatic pain, laminectomy for removal of such cartilaginous protrusions was infrequent. Today, laminectomy for removal of protruded disks is one of the commonest of neurosurgical operations performed at The Mayo Clinic.

A clear understanding of the nature of the normal intervertebral disk and of its relationship to the two adjoining vertebral bodies, to the posterior longitudinal ligament, to the intervertebral foramina and to the spinal cord and nerve roots is essential to full appreciation of the rôle which the cartilaginous intervertebral disk plays in the production of chronic continuous or of intermittent and recurring low back and sciatic pain.

The intervertebral disk is composed of two parts: (1) the annulus fibrosus, a rather dense, elastic fibrocartilage, which is intimately attached to the margins of the adjoining vertebral bodies; (2) the nucleus pulposus, a very soft resilient tissue which is enclosed, and in the normal state is maintained by the annulus fibrosus. Normally, the posterior longitudinal ligament, which extends from the second cervical vertebra to the sacrum, and thus forms a part of the anterior wall of the spinal canal, aids in the maintenance of the intervertebral disk within its position. The spinal cord, surrounded by its meninges, lies directly posterior to the posterior longitudinal ligament and the paired spinal nerves emerge from the dural sac and leave the spinal canal at the intervertebral foramina. A more detailed study of the spinal nerves and their relationship to the intervertebral spaces is necessary for a clear understanding of the way in which a particular protruded disk may involve a given nerve root. The fact that the spinal nerves do not come off at right angles and do not immediately leave the spinal canal opens the possibility of considerable variation occurring in the impingement of some of the disks on the nerve roots.

Intervertebral disks occur throughout the spinal column from the space between the second and third cervical vertebræ to the coccyx. Those present in the fixed vertebral segments (sacrum and coccyx) are rudimentary, however, and rarely, if ever, are protruded with the resultant production of low back and sciatic pain.

As far as is known, any of the others may be protruded, although there are certain disks which seem particularly vulnerable.[6] At the clinic we have encountered several protrusions in the cervical and thoracic regions of the spinal column, but by far the largest number of protrusions encountered have been in the lumbar region.



Etiology and Pathology of Protruded Intervertebral Disk

The nucleus pulposus consists of a semisolid substance and when stress or strain is applied to the back the nucleus pulposus may be forced against the elastic annulus fibrosus and cause considerable stretching of this latter structure. When the stress is ended, normally the disk returns to its usual position. When unusual stress or strain is applied to the back the annulus fibrosus may be injured and then a portion of the disk escapes from its normal position between the vertebræ. The portion of the disk which escapes or protrudes may consist of a pea-sized fragment of fibrocartilage, or it may be several centimeters in length and breadth (Fig. 1). The majority of the protrusions, however, are small and their ability to produce symptoms depends on their relationship to nerve roots.

It is my feeling that true protrusions of intervertebral disks are a result of undue stress or strain placed on the fibrocartilaginous annulus fibrosus. The stress may be secondary to the lifting of a heavy object,[2] the cranking of a tractor, forceful unexpected sitting (such as on a slippery pavement) or to a blow on the back. Whether there is one or more than one predisposing cause which makes one individual more susceptible to this lesion than another I am unprepared to say. It is true that many of our patients at the clinic have had congenital anomalies of the spinal column, particularly in the region of the lumbosacral joint. These anomalies have consisted of the presence of four or six lumbar vertebræ instead of the usual five; partial or complete sacralization of the last lumbar vertebra; partial or complete lumbarization of the first sacral vertebra; incomplete fusion of the laminæ posteriorly, with the occurrence of spina bifida occulta and of anomalies of position of the articular facets, particularly of those of the fifth lumbar and first sacral vertebræ. About 25 per cent of our patients have been unable to recall an injury to the back even after a protruded disk has been removed.[7]

The cartilage which protrudes into the spinal canal and encroaches on the spinal cord or on one

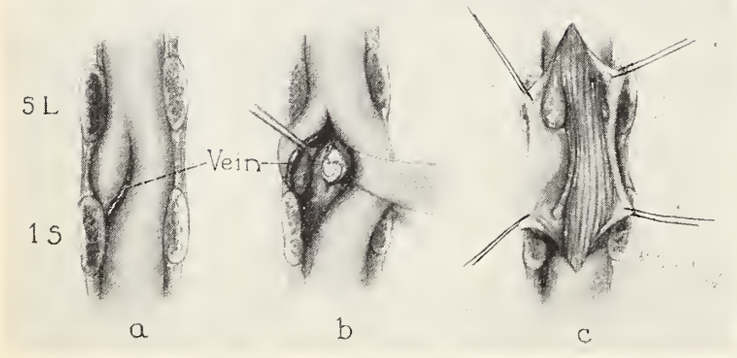


Fig. 1 (*upper left*). Protruded portion of lumbosacral disk removed at operation in a case in which backache and sciatica had endured for one year. Complete relief was obtained following removal of the protruded portion.

Fig. 2 (*right*). In this case a portion of a protruded disk had perforated an hypertrophied ligamentum flavum.

Fig. 3 (*lower left*). The findings at operation in a case in which backache and left sciatic pain had endured for twelve years. *a*, the characteristic enlargement of the nerve root; *b*, the thinned out posterior longitudinal ligament has been incised and the protruded portion of the disk is escaping; *c*, enlargement of the intradural portion of the fifth lumbar and first sacral nerve roots on the left. The remainder of the cauda equina is normal.

or more nerve roots may be small or relatively large, as large as a section of the cord itself. So far as I know, however, the entire disk never protrudes and since surgical treatment of this condition consists in removal of the protruded portion of the disk, the entire disk is never removed. Some of the protruded portions are so small that they may be overlooked on superficial examination of the intervertebral space. Some, however, are so large that they obstruct the spinal canal and appear and feel as if they were large, intraspinal neoplasms. At times the disk is so completely fragmented that loose fragments of cartilage may be found lying on the dorsal aspect of the dural sac. In one case, a piece of disk tissue was found, having perforated a ligamentum flavum (Fig. 2). In the majority of cases, however, the findings are similar and characteristic. The majority of the protrusions occur laterally (the central part of the posterior longitudinal ligament is strongest and there are deficiencies laterally) and thus the unilaterality of symptoms and signs is explained. The nerve root compressed by the protruded disk is always enlarged owing to injection and edema secondary to the compression (Fig. 3). The enlarged nerve root is usually elevated and appears more posterior than does its fellow of the opposite side. At times the enlarged nerve root is displaced mesially or laterally by the protruded disk. The variations of the relationship of the protrusion to the nerve root cause minor variations in the technic of removal of the protruded portion. Ordinarily the protrusion appears as a smooth, rounded or dome-shaped tumefaction, the resilience of which is easily tested when slight pressure is applied to it with an instrument. Occasionally, when the involved nerve root is retracted, one or more loose fragments of cartilage will pop out free into the canal and they are lifted from the wound with forceps. The usual condition, however, requires incision of the "cap-

sule" which allows the bulging cartilaginous fragments to escape. The capsule is a thinned portion of the posterior longitudinal ligament. The fragments unwind, as it were (Fig. 3*b*), as they escape through the incision in the ligament, and they appear much like ragged pieces of tendon which have been matted together in a small ball. The protrusions vary in consistency from that of soft mucoid material to the bony hardness of complete ossification.

Microscopically, various degrees of degeneration are noted. There may be simple edema or there may be various stages of hyaline degeneration, calcification or ossification. The tissue contains both nuclear and annular material[1] and it is for that reason that we prefer to designate the lesion by the term "protruded disk" rather than "herniated nucleus pulposus," "rupture of the intervertebral disk," or any of the other terms used in connection with injury and extrusion of the intervertebral fibrocartilage. True neoplasms of the disks occur, but that is another subject and is not to be considered in this paper.

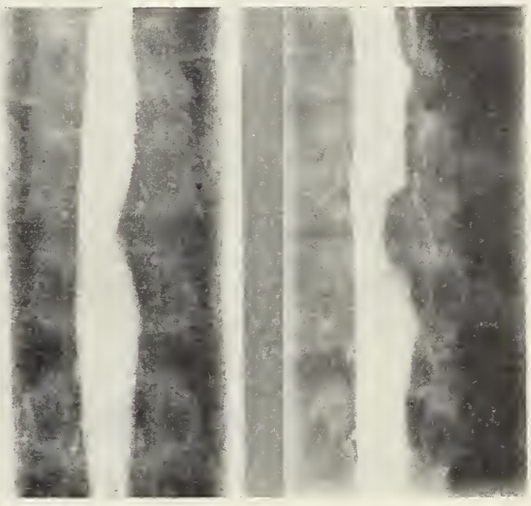

Fig. 4 (*left*). Protruded portion of fourth lumbar disk which had produced paraplegia and complete subarachnoid block. The smaller specimen represents the hypertrophied overlying ligamentum flavum.

Fig 5 (*right*). Postero-anterior and antero-posterior roentgenograms which demonstrate a defect in the column of lipiodol opposite the eleventh thoracic intervertebral space. The patient had had backache without sciatica for ten years. At operation an hypertrophied ligamentum flavum was resected and a protruded portion of the eleventh thoracic intervertebral disk was removed. The patient has been relieved of his backache.

Symptoms and Diagnosis

The symptoms produced by protrusion of an intervertebral disk vary according to the disk involved and the site at which the protrusion occurs in relation to the particular disk. If the protrusion occurs in the midline in the cervical or thoracic region of the spinal canal the symptoms are likely to be those of compression of the spinal cord by an intraspinal neoplasm. If the protrusion into the spinal canal occurs laterally, as it most often does, then the early symptoms are those of irritation of a nerve root and, later, those of interruption of the impulses that travel along that nerve, owing to severe compression. Large protrusions in the lumbar region may give all the symptoms and signs of an intraspinal neoplasm and produce paraplegia by compressing the cauda equina and interrupting all nerve function below the level of the lesion (Fig. 4).

Of all the protrusions of disks for which we have performed laminectomy (more than 200) about 90 per cent have occurred in the lumbar region and the most common symptom has been sciatic pain.[3] The pain in the course of the sciatic nerve, on one side or, more rarely, both sides, may be and usually is associated with more or less pain in the lower part of the back. The low back pain is situated in the lumbar region, lumbosacral region, over the sacro-iliac synchondroses, or it may exist chiefly in the buttocks. A small percentage of patients have had low back pain without projection of the pain along sciatic nerves. When low back pain exists for a considerable period without projection along one or both sciatic nerves, the protrusion is more likely to be in the lower thoracic region than in the lumbar region (Fig. 5).

The patient who has a protruded intervertebral disk usually gives a history of trauma to the spinal column. However, about a fourth of the

patients are unable to recall any distinct injury.

The pain of which these patients complain partakes of the usual characteristics of root pain. That is, the pain follows the anatomic distribution of the peripheral nerve which has its origin in the nerve root involved. The pain is usually aggravated by coughing, sneezing and straining, or by anything that increases the pressure of the spinal fluid. Some of the patients state that they are unable to sleep at night because of exacerbation of their symptoms in the small hours. Others state that they are comfortable while recumbent.

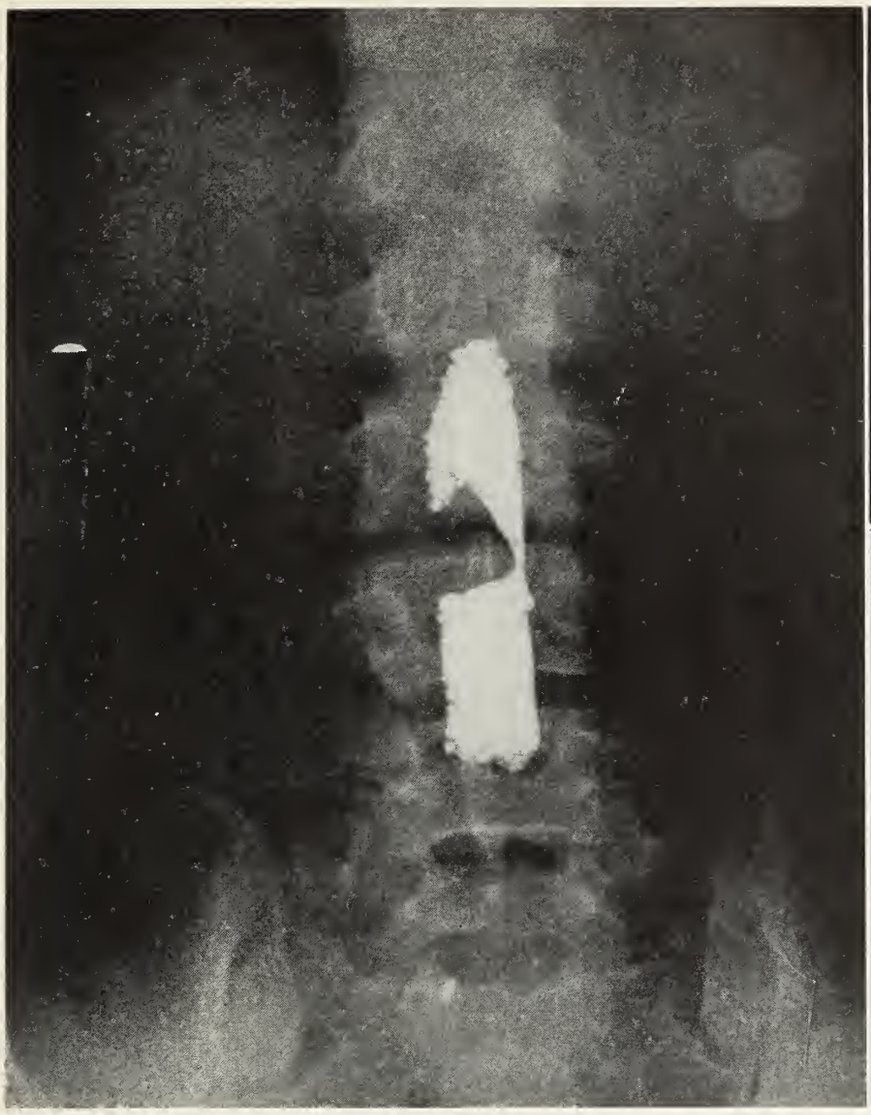
If the lesion has been present for a long time, is large, or there have been repeated exacerbations of symptoms, weakness and numbness of the involved member may constitute a major complaint.

One of the most important points in the history of a patient who has a protruded disk is the fact that, in spite of treatment by the long accepted methods, the symptoms have persisted. When low back or sciatic pain fails to respond to the usual conservative orthopedic measures a protruded disk as the causative factor should be considered.

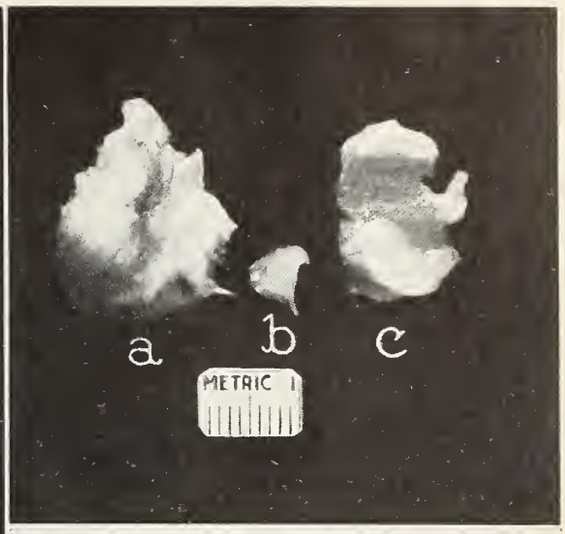
On examination, the patients frequently exhibit scoliosis and they move about cautiously in order to prevent jarring and thus exaggeration of their pain. When sitting down or rising from a sitting position they guard their motions. When a considerable number of these patients have been seen the diagnosis in a given case can be surmised after observing the patient rise from a sitting position and walk across a room. The posture and gait are often characteristic.

When the patient is disrobed and examined one notes, in addition to the scoliosis, spasm of the erector spinæ muscles. Raising of the straight leg produces severe pain, and motion of the involved lower extremity, as well as of the spinal column, is limited.

The neurologic findings vary considerably. In the presence of larger lesions definite paralysis exists. There may be more or less complete paralysis of both lower extremities. The vesical and anal sphincters likewise may be paralyzed. The majority of the patients, however, display few objective neurologic findings. The most constant finding is diminution or absence of the Achilles tendon reflex on the involved side. There may be or may not be sensory loss and tenderness along the course of the involved nerve.



The roentgenographic findings are not specific for protruded intervertebral disk. All patients should be subjected to careful roentgenologic studies in order to exclude other conditions which might account for their symptoms. Particularly, tuberculosis and malignancy of the vertebræ should be excluded.



The spinal fluid should be examined in all cases of intractable low back and sciatic pain. The most important finding in cases of protruded intervertebral disk is elevation of the concentration of total protein. In about 75 per cent of cases the total protein of the spinal fluid will be more than 40 mg. per 100 c.c. Discovery of subarachnoid block on lumbar puncture is rare, but when it exists extensive paralysis is usually present also. In the presence of subarachnoid block a diagnosis of intraspinal neoplasm usually is made. If lesions are caudal the reversed Queckenstedt test is positive.[2]

Although the diagnosis of protruded intervertebral disk can be, and often is, made on the basis of the history and physical findings, it is at present essential in the majority of cases that the diagnosis be confirmed before advising operation for removal of the protruded portion of the disk.

The diagnosis can be confirmed in most cases by fluoroscopic examination of the spinal canal after subarachnoid injection of an opaque material. The opaque material which we are using is 40 per cent iodine in poppy seed oil (lipiodol). Five cubic centimeters of this substance are injected through a spinal puncture needle into the lumbar subarachnoid space. Careful fluoroscopic observation of the movements of the oil while the patient is being tilted on a tilting fluoroscopic table is essential to detect the smaller lesions.

A word of advice regarding introduction of the lipiodol may be worth while. It never should be used in the presence of a suspected inflammatory lesion. It never should be introduced at a temperature above that of the body. It should not be used if it is cloudy. In cases in which a lesion of a disk is suspected, it is my practice to inject the lipiodol through the second or third lumbar interspace, since about 90 per cent of the lumbar protrusions occur at the fourth or fifth interspace. Introduction of the lipiodol at the level of the protrusion is at times painful and there is an increased chance, because of distortion of the dural sac, of the lipiodol spreading

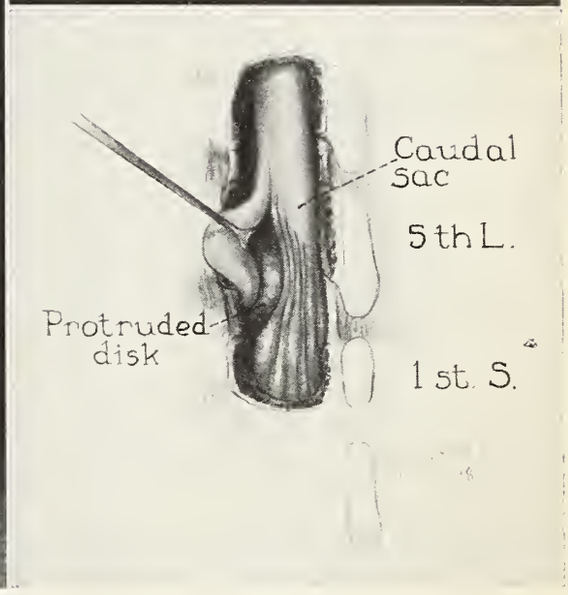


Fig. 6 (*left*). Postero-anterior roentgenogram showing defect in the column of lipiodol opposite the third lumbar intervertebral space on the left. This defect is characteristic of protruded intervertebral disks. The patient had sustained an injury of his back a year and a half previously and had suffered backache and left sciatic pain since.

Fig. 7 (*upper right*). Specimens, removal of which relieved a man of chronic backache and sciatica of one year's duration. *a*, protruded portion of fifth lumbar disk; *b*, corresponding portion of the ligamentum flavum between the sixth lumbar and first sacral vertebræ. This ligament was not abnormal. There were, in this case, six lumbar vertebræ; *c*, the ligamentum flavum between the fifth and sixth lumbar vertebræ. The ligament was markedly thickened.

Fig. 8 (*lower right*). Exposure, by means of hemilaminectomy, of a protruded lumbosacral disk. The patient had had backache and left sciatic pain for fifteen years. The study with lipiodol was negative because the caudal sac ended above the level of the protrusion.

extradurally. The defect produced in the column of lipiodol by a protruded intervertebral disk usually is characteristic (Fig. 6). The defect usually is anterolateral in position and is situated opposite the intervertebral space. In addition to the defect produced by the disk itself, often a defect owing to the enlarged, edematous, involved nerve root can be detected in the shadow of the lipiodol. Recently we have come to recognize defects attributable to hypertrophy of the ligamentum flavum. This abnormality of the overlying ligament is, I feel, a more or less constant accompaniment of protrusion of an intervertebral disk (Fig. 7). There are, however, cases in which hypertrophy of the ligamentum flavum causes low back and sciatic pain without associated protrusion of a disk. This condition, occurring as a single lesion, however, in our experience, is much less common than is hypertrophy of the ligament associated with true protrusion of the underlying disk. In every case careful search should be made to exclude an associated lesion of a disk.

As our experience has increased, on a few occasions we have advised laminectomy for protruded disk in the face of negative examination with lipiodol. Whenever this is done the patient should be advised of the possibilities and the operation should not be performed until every other condition which might account for the patient's symptoms is excluded.

Occasionally a patient will be encountered in

examination of whom a positive test is impossible for anatomic reasons. The caudal sac may end above the lumbosacral space and thus the lipiodol cannot reach the level of protrusion (Fig. 8).

Treatment

There is only one treatment for protrusion of an intervertebral disk that is producing compression of the spinal cord or of a nerve root. When a definite protrusion is demonstrated and a lesion at the level of the protrusion will explain the patient's symptoms and signs, laminectomy for the express purpose of removing the protruded portion of the disk should be performed. Anyone who has witnessed the operative removal of a protruded disk and seen the relationship of the abnormal cartilaginous mass to the spinal cord or nerve root, the edema, the enlargement and displacement of the nerve root and the complete relief of pressure following removal of the protruded portion will agree, I feel sure, that there is a definite anatomic and pathologic basis for the condition under discussion (Fig. 3). If there still should be any doubt, to see the patient when he leaves the hospital two weeks later, free of pain, free of scoliosis and smiling is sufficient to convince even the most skeptical.

In performing laminectomy for protruded intervertebral disk, removal of two spinous processes and of two pairs of laminæ is, in the majority of cases, sufficient to obtain adequate exposure. The articular facets should be preserved. Resection of the ligamentum flavum, which is found to be hypertrophied in most, if not in all cases, aids materially in obtaining satisfactory exposure of the involved nerve root and the underlying protruded part. Since most of the protrusions are lateral to the common dural sac, most of them can be removed extradurally before the dural sac is opened. Leaving the dural sac intact serves three distinct purposes: there is less bleeding from the extradural vessels while the hydrostatic effect of the cerebrospinal fluid is active; the cerebrospinal fluid acts as a buffer to protect the cauda equina while the dura mater is being retracted, and finally if one should be unfortunate enough to encounter a previously unrecognized extradural inflammatory lesion, the subarachnoid space and its contents would be protected from contamination.

After the protruded portion of the disk has been removed the dural sac is opened and the interior inspected. Edema of the intradural portion of the involved nerve root is noted (Fig. 3*c*). The canal is carefully inspected to be sure that all pressure has been removed. The lipiodol is sucked out before the dura mater is closed. Bone graft or fusion is not necessary.

Following operation the patients are kept in bed for twelve days. They are allowed to leave the hospital on the fourteenth day and to return to their homes three weeks after operation. They are advised to refrain from heavy lifting or from placing stress or strain on their backs for three months. After this time they are encouraged to return gradually to their former activities. The period of hospitalization and period of convalescence is much shorter than it would be if bone grafting were performed. This is, of course, a tremendous saving in expense to the patient and he is enabled to return to work much sooner. The hypertrophied ligamentum flavum is resected in the course of exposing the protrusion.

Results

Our results justify continuation of our present treatment, namely, laminectomy and removal of the protruded portion of the disk. Most of the patients are completely relieved of their symptoms and are able to return to their former occupations. There has been one postoperative death in more than 200 laminectomies for protruded intervertebral disk. There has been one recurrence. This patient was completely relieved following a second operation.[4]

Discussion

Dr. Harold O. Peterson, Minneapolis: I am sure that Dr. Love and his associates have had more experience with posterior protrusion of the intervertebral disc than any other person or group, and I heartily agree with everything he has said. Since my experience has been limited largely to the roentgen diagnosis of this condition I shall confine my remarks to this phase of the subject.

I was gratified to hear that Dr. Love is still as en-

thusiastic about the diagnosis and treatment of this condition as he was when the original reports were made. Although it is several years now since the first papers were published and even though the condition is known to exist by many it is still difficult in some places to obtain a satisfactory examination in order to establish the diagnosis. By a satisfactory examination is meant the injection of lipiodol into the spinal canal in sufficient quantities (5 c.c.) to permit a thorough radiographic examination.

This is due entirely to the fear of injecting a foreign substance such as lipiodol into the subarachnoid space. In a review of the literature one year ago I was able to find only a few isolated instances in which it was probable that permanent damage had followed its use. Those who had used lipiodol the most reported no serious consequences, although many patients had temporary ill effects which disappeared after the second or third day. Therefore, although there may be an occasional case which shows undesirable cord and nerve root damage subsequent to lipiodol injection, the information which can be obtained only by this method outweighs the danger of any possible ill effects.

The indiscriminate intraspinal injection of lipiodol into every patient with a backache is, however, not justified and it is for this reason that a thorough orthopedic and neurologic examination is necessary in every case to exclude all other possible explanations of the pain. Dr. Love has adequately outlined the indications for lipiodol study, and I merely wish to emphasize a few points. Lipiodol study of the spine should be reserved for those cases of chronic back pain which have failed to respond to conservative treatment and is contra-indicated in those patients with acute back pain of short duration. Ordinary roentgenograms must be taken of the spine before lipiodol injection is considered. I recall one case in which a diagnosis of metastatic malignancy was readily made on the films taken after lipiodol injection, there having been no previous films made. It should be understood, however, that a positive diagnosis of herniated disc cannot be made from the plain roentgenograms alone. Suggestive findings may be present in at least half of the cases consisting of narrowing of the intervertebral disc, straightening of the normal lumbar lordosis, and scoliosis.

The lesion which Dr. Love has described explains on a sound anatomic and pathologic basis many of the cases which have been heretofore loosely and incorrectly diagnosed as sciatica or sacro-iliac disease. It is difficult to understand how sacro-iliac disease, per se, can ever produce sciatic pain. It must be remembered, however, that all cases of low back pain, even if sciatic radiation is present, are not due to herniated discs. Since these cases are clinically indistinguishable in many instances from what is usually called sacro-iliac disease, sciatica and low back strain, it is essential that a lipiodol study be made. By this method of examination 90 to 95% of the cases can be correctly diagnosed and localized.

In closing I should like to emphasize the necessity of thinking of this condition in those patients who have intractable low back pain and especially where there is sciatic radiation. If the usual methods of treatment fail, lipiodol injection is indicated.

THE VALUE OF THE X-RAY IN GENERAL PRACTICE*

CHARLES G. SUTHERLAND, M.D.
Rochester, Minnesota

EARLY in the eighteenth century, a French physicist of peasant birth spent many hours on research concerning the passage of an electric current through a tube from which the air had been evacuated. A curious void contrivance which he constructed at that time and which not inappropriately was called the "electric egg" undoubtedly represented the earliest and humblest ancestor of the modern vacuum tube.

Nearly eighty years passed before further activities in this field of scientific research were initiated. The new light which Wilhelm Conrad Roentgen discovered, in 1895, was actually produced in 1785 and many times after that, but it was not recognized until the discovery by Roentgen. Roentgen gave the new light the name of "x-ray"; in his honor it was later called the "roentgen ray" and the new science which developed from his discovery was given the name of roentgenology.

The possibilities of the x-rays as a diagnostic agent in medicine were discussed before the Berlin Medical Society the day previous to, and before the Society of Internal Medicine in Berlin the day of the announcement of the discovery. By the end of February, 1896, the method was in comparatively general use as a new diagnostic procedure in many countries.

The epochal feature of the roentgen rays was that they supplemented conjecture in medicine with visual and graphic factual evidence. Because of technical difficulties, it was many years before the application of the method became practical in routine investigation. The World War was probably a real factor in stimulating interest in this new field of investigation. The demand for machinery and accessories necessary to the production of roentgenograms and the visualization of various anatomic parts fired the imagination of the industrialist and encouraged the expenditure of time and money in research which resulted in the production of the paraphernalia required.

*From the Section on Roentgenology, The Mayo Clinic, Rochester, Minnesota. Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

Concomitant with this industrial research went the correlation of roentgenologic findings and the already known facts of clinical and pathologic investigation. The pioneers in this work established new foundations in the appearance of normal structures and the normal limit of their variations. They proved that the roentgenographic image was a reproduction in relief of the various components of the body, normal and abnormal. They found that the idiosyncrasies of individual disease entities, expressed in predilection for certain types of tissue and definite situation in particular structures, long known to the pathologist, could be graphically recorded. In short, they discovered that roentgenology afforded the opportunity to study pathologic changes in the living patient. Experience with the new method revealed a new and unique advantage: by serial roentgenography it was possible to study the changes resulting from the progression or regression of the individual morbid process and thereby evaluate specific forms of therapy and at the same time more accurately establish the prognosis.

Radiotherapy has become a definite factor in the establishment, or in the corroboration, of a diagnosis. For example, the changes produced by radiotherapy in Ewing's tumor are characteristic enough to be diagnostic.

With the aid of substances ingested or injected or autogenously produced after the injection or ingestion of chemical compounds, most of the viscera of the body were rendered visible in roentgenoscopic observation or in the roentgenogram. Other viscera were made visible by the introduction of air or gases. The anatomist, the physiologist, and the pathologist, working with the aid of roentgenography and roentgenoscopy, have added materially to the sum of knowledge of their special subjects.

The value of the roentgen rays in general practice is familiar to most of you; time will only permit discussion of a single phase of the subject, the use of the method in the diagnosis of lesions involving bone.

Let me sound a note of warning. The interpretation of roentgenologic findings is not to be undertaken lightly. It involves a serious responsibility. An error in conclusion may influence subsequent therapy to an extent that might be embarrassing and even disastrous to the interests of the patient and to professional reputation.

To avoid such disaster, one must have some knowledge of the fundamental changes in the architecture of bone peculiar to certain diseases. This point can best be illustrated by considering the salient features of the benign and malignant neoplasm of bone. The decision of paramount importance that one may be called on to make is whether a given lesion involving bone is inflammatory or neoplastic, and, more important still, if neoplastic, is it benign or malignant in nature. Of lesser importance, but still very helpful in later consideration, is whether the lesion is a primary neoplastic one or whether it is a secondary (metastatic) implant in bone from a malignant tumor in some remote part.

The importance of this statement lies in the fact that not infrequently in a case in which the lesion has been considered comparatively innocuous the roentgenogram reveals a primary malignant tumor or metastatic involvement. The metastatic involvement may be the first indication of a malignant lesion in the body and may institute a search for the primary neoplasm.

To lessen the confusion resulting from any elaborate attempts at classification, this discussion will be limited to the main groups of lesions recognized by the committee of the Clinical Pathological Association and their simulants. To enable consideration in sequence I have rearranged this classification as follows: (1) benign osteogenic tumors, (2) periosteal fibrosarcoma (extraperiosteal sarcoma), (3) noninflammatory conditions simulating benign lesions of bone, (4) giant cell tumor, (5) benign angioma, (6) myeloma, (7) malignant osteogenic tumors, (8) inflammatory conditions simulating malignant lesions of bone, (9) Ewing's tumor (Ewing's sarcoma), (10) malignant angioma, and (11) metastatic involvement.

Benign Osteogenic Tumors

The word "osteogenic" is used here, not in the sense of bone forming, but simply to designate a tumor arising from bone cells or bone-forming cells in contradistinction to tumors that originate in bone marrow cells or in the vessels of bone or bone marrow. The outstanding roentgenographic feature of a benign tumor of bone is the retention of the cortical contour. The cortex may be expanded or otherwise deformed but there is never any dissolution of its continuity. On the other hand, the almost pathognomonic

characteristic of the maligant osteogenic tumor is the definite break in the continuity of the cortical outline. This, with but few exceptions, which will be mentioned, is the prominent feature of malignant tumors of bone.

Turning to the pathology of these lesions, one finds that these features have been described. In 1925 Broders said: "The chief difference between the average benign neoplasm and the average malignant one is that the benign exerts more control over itself than the malignant. It cannot be said that any neoplasm has complete control of itself at all times, because the very fact that it grows shows that its control is not absolute, but, fortunately for the human race, the majority of neoplasms do reach a point of absolute self control, or, in other words, obey the law of limitation of growth. . . . Benign neoplasms produce a structure in which the cells are practically indistinguishable from the cells of normal tissues, although the arrangement is somewhat different, and unquestionably a number of benign neoplasms function to some extent like the tissues they so closely imitate . . . All benign neoplasms, like the tissues which they imitate, produce regenerative cells as well as differentiated cells; otherwise they could not grow, because the differentiated cells do not reproduce. It is also reasonable to believe that the regenerative cells of benign neoplasms are more active than the regenerative cells of normal tissues, and that the regenerative cells of certain benign neoplasms are more active than the regenerative cells of others, because they grow faster than others. It may be that the regenerative cells of benign neoplasms are more numerous than those of others.

"When benign neoplasms reach the point of complete self control, their cells either cease to regenerate or they differentiate beyond the point of regeneration. If all the cells of a benign neoplasm have differentiated beyond the point of regeneration, there is only one thing for the neoplasm to do, and that is to degenerate, and this probably often takes place, especially in myomas of the uterus. Degeneration seems to be one of Nature's methods of getting rid of neoplasms . . . In passing from benign to malignant neoplasia, the fact should not be lost sight of that the power of self control still exists, although to a gradually diminishing degree. A wart that has been slowly growing for a number of years may show evidence of increased rate of growth, and after it has been excised and examined under the microscope, cells are observed at its base that differ from those found at the base of the ordinary benign wart . . . The regenerative cells at the base of this wart have undergone . . . anaplasia (undifferentiation), or a process of dedifferentiation . . . These anaplastic or dedifferentiated cells appear to represent a new type, and are observed in all forms of malignant neoplasia, although they vary in shape and size in different types of malignant neoplasms . . . These anaplastic or dedifferentiated cells have various potentialities . . . I wish to emphasize here a good potentiality, or the power to produce cells that differentiate or reach a state of maturity beyond their ability to reproduce. This differentiating or controlling quality ranges from practically nothing to almost 100 per cent. The cells of a neoplasm that show practically no tendency to control themselves rapidly infiltrate the adjacent structures and, by utilizing the vascular system as a means of metastasis, set up colonies in various parts of the body, which in turn keep on producing their own kind of cells, finally with a fatal result. On the other hand, if the cells of a neoplasm show a marked tendency to control themselves by differentiation the neoplasm will grow slowly, and show very little tendency to metastasize; or if some of the cells do metastasize, they will in turn set aside the large majority to differentiate and build a structure similar to that found in a normal organ, which functions to some extent. . . .

"Malignant neoplasms need not necessarily be preceded by benign neoplasms; the large majority are not. Many are preceded by destruction of tissue, but others spring up without the slightest injury, so far as we know . . . It would seem that this type can only be explained by heredity. These should be called true spontaneous neoplasms."

When one studies the so-called benign tumors of bone it immediately becomes apparent that the majority of them at least, if not all of them, occur in early life and at about the age of puberty. Most of them are situated at the growing ends of bone and in many cases there is a distinct tendency toward cessation of growth and even regression at about the period when the development of the skeleton is complete. All of these facts point to a disturbance in develop-

ment of the cartilaginous elements in the formation of bone and joints. It may be difficult in some cases to draw the line between the abnormal and the normal state. For example, limited outgrowths of preëxisting cartilage occurring in the ribs and about the joints are distinguished as ecchondroses. True progressive neoplasms which are composed of cartilage appear in the same situations and also in tissues which normally do not contain cartilage; these neoplasms are called enchondromas or chondromas. Chondromas are familiar to most of us as single or multiple tumors of the hands and feet. In some chondromas the formation of cartilaginous matrix is imperfect and a simple hyaline material results. Roentgenographically such a tumor is transparent to the roentgen rays; it will only cast a shadow by virtue of its bulk. In cases of smaller tumors the only evidence in the roentgenogram may be a filling defect in the bone, which has a smooth margin; this is the result of erosion of the tumor by pressure. Calcification with the deposit of phosphate and carbonate of lime may cause incrustation of both the matrix and the cells and may produce a characteristic roentgenographic image. The tumor may be partly fibrillated and be recognizable as a fibroma. Mucinous material may take the place of the matrix; in such cases the prefix myxo is used in the pathologic nomenclature. Ossification of chondromas occurs; depending on the preponderance of bone or cartilage, the tumor is known as an osteoma or osteochondroma. These subdivisions of this group of tumors can all be recognized by their roentgenographic images.

The exostosis occurs in two forms: (1) the single outgrowth of bone which is capped by a cauliflower shaped excrescence of cartilage, and (2) the multiple symmetrically distributed lesions of the same type, which are familiar to most of us as multiple congenital exostoses or hereditary deforming chondrodysplasia. If one accepts Keith's explanation of the occurrence of the latter type, that is, a congenital defect in the periosteum which normally acts as a ferrule in the control of the architecture of bone, and if one accepts the opinion that benign tumors of bone are due to a disturbance in development of the cartilaginous elements in the formation of bone, then all the lesions which have been mentioned are in the same category. Their roentgenographic images confirm this opinion. The control stressed by Broders is perfectly apparent in the roentgenogram. In the benign osteogenic tumor the contiguous soft tissue structures are only invaded by the expansion of the cortex of the bone.

In the malignant osteogenic tumor, the tumor breaks through the cortex and "promiscuously" invades the surrounding soft tissue structures. The latter exemplifies the loss of control which Broders pointed out as the characteristic of the malignant neoplasm.

These two facts, the retention throughout or the dissolution at some point of the cortical contour, and the sharply demarcated or the promiscuous invasion of the adjacent soft tissue structures are the keynote of the roentgenologic differentiation of benign and malignant tumors.

The greatest value of the roentgen rays is, of course, in the decision of the nature of the morbid process. This establishes the prognosis. If the benign tumor is of the osteogenic type, the treatment will be conservative. Obviously, surgical intervention is contraindicated at least until mature growth is attained. Unless demanded because of mechanical interference with function or some other complicating factor, surgical removal of these tumors should not be attempted. Unless every last cartilage cell can be removed or destroyed, these tumors will recur. In recurrence, there not infrequently is a mutation of the cell and a chondrosarcoma or an osteochondrosarcoma results. These tumors grow slowly; a sudden acceleration of growth and occurrence of new symptoms call for roentgenographic examination and careful search for evidence of dissolution of the cortical contour and promiscuous invasion of the contiguous soft tissues, which indicate sarcomatous change.

Of the nonosteogenic tumors involving bone the benign hemangioma is comparatively rare. This neoplasm involves the shafts of long bones, the skull and the vertebral bodies. In the shafts of the bones it occurs in the region of the metaphysis; it expands the cortex but does not extend deeply into the medullary or cancellous spaces; the roentgenographic image is that of a "soap-bubble" and is somewhat similar to that of a giant cell tumor. In the vertebral body the image is characterized by vertical striæ on a background of decreased density. Pathologic fracture is commonly a complicating factor.

The two most important simulants of benign

osteogenic tumors are cysts in bone and giant cell tumors. Solitary cysts of bone almost invariably involve the metaphysis. They probably arise in childhood and may be latent for many years. Pathologic fracture may first call attention to the lesion. Cysts may have their origin in infection or trauma with subsequent hemorrhage. Solitary cysts in the middle of the shaft of bone are usually the result of osteodystrophia fibrosa (osteitis fibrosa cystica), a condition in which the bone marrow is transformed into a fibrous connective tissue that is rich in giant cells. There is a resorption of the compact cortex, followed by replacement with finely porous, and often with uncalcified, new bone. Within these fibrous portions are cysts and so-called solid brown tumors composed of numerous, multinuclear giant cells in a spindle cell matrix containing deposits of hemosiderin. The generally accepted hypothesis is that trauma with hemorrhages into the bone marrow is one of the etiologic factors of this condition. The products of hemorrhage remain localized. Maintenance of functional activity acts as an irritant and produces secondary hemorrhages. Owing to the peculiar structure and circulatory system of bone, a permanent congestion of the blood and lymph vessels is produced. This congestion, together with continuous mechanical irritation, leads to osteodystrophia. With the development of bone, the cyst may be carried toward the central portion of the shaft, producing the localized form of osteodystrophia fibrosa (osteitis fibrosa cystica or fibrocystic disease). Osteodystrophia fibrosa generalisata is now generally recognized as an end-result of advanced parathyroid disease.

The consensus is that giant cell tumor is a granuloma and that it most probably has the same origin as does osteodystrophia fibrosa.

Simple cyst, osteodystrophia fibrosa and giant cell tumor would seem, therefore, to fall in the same category. In these tumors there seems to be a reparative process that has got out of control.

Peculiarly, the situation of a giant cell tumor is preponderantly in the epiphysis, where it apparently has its origin in trauma or infection. The activities of the fibroblasts are outdone by those of the giant cells (osteoclasts). The tumor assumes an asymmetrical position in the epiphysis because it commences beneath the cortex and extends toward the central portion of the epiphysis at the expense of the cancellous bone. Primarily it is traversed by trabeculæ which divide the tumor into several loculi. Later these trabeculæ may disappear and may be replaced by a homogeneous flat shadow in the roentgenogram, owing to a lysis in the central portion of the bone; this lysis may extend into the cortex and leave only a thin shell of bone. This thin shell of bone may be expanded until it becomes invisible in the roentgenogram and the tumor may extend beyond the cortex and push the soft tissues ahead of it. At this stage it may be very difficult to differentiate roentgenographically a giant cell tumor and a malignant neoplasm. In a case of giant cell tumor careful study of the outline of the soft tissue shadow will reveal that it has a smooth margin and is intact. A remnant of the cortical shell persists as a wavy outline of bone which passes over the soft tissue shadow at the proximal end of the bone. Occasionally, the shaft of the bone may be telescoped for some distance into the soft tissue shadow. In some cases the evidence of a benign tumor may all be masked and the roentgenographic interpretation may be extremely difficult, but a careful study of the soft tissue invasive shadow will usually reveal some evidence of the continuity of the outline of the shadow.

Periosteal fibrosarcoma (extraperiosteal sarcoma) occasionally presents a roentegenographic image that simulates very closely that of a benign osteogenic tumor or more often that of a giant cell tumor. Periosteal fibrosarcoma invades the bone from without and the destructive lesion in bone, when the bone is involved, is frequently the result of pressure erosion. In such cases the filling defect in the bone has a smooth margin and the continuity of the contour shadow is maintained.

Myeloma is the other malignant lesion that involves bone and simulates a benign tumor roentgenographically. In fact, myeloma violates every principle suggested for the differentiation of benign and malignant tumors. In the shafts of long bones and in the skull this lesion is characterized by multiple, small, discrete filling defects in the bone shadow and the margins are as clear-cut as if they had been made with a steel punch. In the ribs and the shafts of long bones a wide expansion of the shaft may occur and although the cortex may be markedly thinned the contour is always maintained just as it is in the benign osteogenic or giant cell tumor. The

shaft of the bone may even be telescoped into the soft tissue shadow as it is in giant cell tumor. In the spinal column complete destruction of one or more vertebral bodies is suggestive of myeloma. In the shaft of long bones pathologic fracture may occur and this may be the first evidence of the morbid process. In the greater number of cases there is general involvement of most of the skeletal structures and there may be difficulty in distinguishing myeloma from the osteoclastic form of metastatic carcinoma. The roentgenogram of the skull offers the most conclusive evidence of the nature of the lesion.

The characteristics of malignant tumors of bone are best exemplified by osteogenic sarcoma. The gradually diminishing degree of the power of self control is apparent in the perforation of the periosteum and the promiscuous invasion of the contiguous soft tissue structures by the tumor mass. Roentgenographically these changes are demonstrable in the roentgenogram as a dissolution of the contour of the cortex and an inability to trace the outline of the soft tissue shadow. The elevation of the periosteum at the proximal end of the lesion is the remaining evidence of the defensive protective measure of the involved bone set up by the periosteum against the continuous aggression of the tumor elements. Sarcoma predominantly involves the metaphyseal portion of the shaft of long bones and extends into the diaphysis. It may involve the diaphysis. When it involves a large flat bone, such as the os innominatum, the filling defect in the bone has an irregular or serrated margin or fades imperceptibly into the surrounding bone, in contradistinction to the smooth margins and well demarcated outline of the filling defect in cases of benign tumors.

Several subdivisions of sarcoma are recognizable in the roentgenograms: (1) subperiosteal and medullary sarcoma; (2) periosteal sarcoma; (3) sclerosing sarcoma; (4) telangiectatic sarcoma (aneurysm of bone); (5) chondosarcoma, and the sarcomas involving the diaphysis.

Careful technic often is required to demonstrate a subperiosteal or medullary sarcoma. In one projection the evidence of the lesion may be so slight as to be missed; in another projection the break in the continuity of the cortex and the "promiscuous" invasion of the soft tissue structures will be easily recognized. The periosteal sarcoma exhibits a "sun-ray" of fine linear bony shadows radiating more or less at a right angle to the axis of the shaft of the bone. In one projection it may be difficult to detect any break in the cortical contour, while in another the characteristic features of the lesion are easily apparent.

The sclerosing sarcoma shows, as the name suggests, an intense eburnation of the involved portion of the bone. Particularly in the upper end of the tibia this tumor may be difficult to distinguish from syphilitic osteitis; only careful study in one of perhaps several projections will reveal the break in the continuity of the cortex. The invasion of soft tissues also tends to be much limited in comparison with other types of sarcoma; it may be so limited as to be difficult of recognition.

The telangiectatic sarcoma (aneurysm of bone) is characterized by a rather extensive bony proliferation in the soft tissues, which in the femur, for example, may very closely simulate a suppurative or other inflammatory lesion of the synovial membrane.

Chondrosarcoma, because of its preponderant cartilaginous content, occasionally offers difficulty in detection of the break in the cortical contour and the soft tissue invasion lacks the extent and the definitely promiscuous features of other types of sarcoma.

The sarcomas involving the mid-diaphyseal portions of the long bones have some of the characteristics of Ewing's tumor, a nonosteogenic tumor which was described as an endothelial myeloma or hemangio-endothelioma by Ewing in 1920.

Ewing's tumor tends to involve the mid-diaphyseal portion of the shaft of long bones, but it may involve any portion; not infrequently, it involves the metaphysis (the growing portion of bone at the junction of the epiphysis and the diaphysis). It rarely affects persons who are more than twenty-one years of age. The bulk of the tumor lies beneath the periosteum; the tumor infiltrates the bone and the bone reacts vigorously with ossification. This reaction is attended with intermittent attacks of fever. The lesion is most often mistaken for osteomyelitis. Roentgenographically, the medullary portion of the bone is not involved. This observation may be of value in the differential diagnosis. In a case recently observed, in which the roentgenographic findings were typical of osteomyelitis of the midshaft of the tibia and in which the pathologist reported that the changes were inflammatory,

the patient returned within seven months with all evidences of a periosteal sarcoma.

Subperiosteal formations may be observed; these may be parallel to the bone (onion-skin laminations) or may be at right angles to the axis of the shaft, as are the miniature sun-ray spicules of bone in Ewing's tumor. The onion-skin laminations and the miniature sun-ray bony spicules have occurred synchronously in the same case. In some of the diaphyseal tumors atypical radiations of bony spicules are seen projecting at or nearly at right angles to the axis of the shaft of the bone; in my experience those have proved on pathologic investigation to be osteogenic sarcomas and this diagnosis has been corroborated by the reactions of the tumor to radiotherapy. A helpful point in differential diagnosis has been the soft tissue invasion shadow. In osteogenic sarcoma this is promiscuous in character; in Ewing's tumor it tends to be indefinitely demarcated. In Ewing's tumor the margin of the invasive shadow is not as sharply demarcated as that of a benign tumor and yet it is more distinct than the line of demarcation that marks the osteogenic sarcoma.

Ewing's tumor should not be confused with traumatic sclerosing osteitis or with infectious nonsuppurating osteomyelitis of Garre; these inflammatory lesions do not show any tendency to lamination of the expanded cortical shadow but exhibit a homogeneous flat density throughout. An intact subperiosteal hematoma is usually more closely confined in area and more frequently projects from only one aspect of the bone than is the case in Ewing's tumor. A ruptured subperiosteal hematoma presents lines of ossification that run parallel to the axis of the shaft, and are much coarser and more widely divided than the onion-skin laminations of Ewing's tumor. Green-stick fracture, with the formation of callus, may be difficult to distinguish from this malignant tumor.

The defensive mechanism of the bone against the advance of Ewing's tumor is very similar to that against the advance of a pyogenic infection; it consists of the creation of a bony shell which is called an "involucrum." An interesting fact is that Ewing's tumor, in contradistinction to osteogenic sarcoma, reacts favorably for a time to radiotherapy. Efficient treatment by this method apparently stimulates the defensive mechanism and results in marked accentuation of the density of the involucrum in the roentgenogram. In all cases of doubt, therefore, a safe procedure is to institute radiotherapy in moderate dosage, as it will be beneficial if the condition is an osteomeylitis. One then should await the results as evidenced in serial roentgenography.

Under such a procedure, some tumors which roentgenographically appeared to be most typical of Ewing's tumor of the shaft were proved ultimately to be osteogenic sarcomas. If careful inspection of the roentgenographic image reveals involvement of the medullary portion of the bone, one should at least suspect osteomyelitis or osteogenic sarcoma.

The malignant angiomas have some of the characteristics of the telangiectatic sarcoma and of Ewing's tumor roentgenographically. Malignant angiomas exhibit an intense subperiosteal proliferation of bony tissue with a subsequent wide invasion of the soft tissues. Under treatment with radiotherapy these tumors show some response, but they do not respond as favorably as does Ewing's tumor.

Metastatic malignant tumors are the result of implants from malignant tumors in parts remote from bone. They have the histologic characteristics of the parent growth. Practically, only carcinoma metastasizes; occasionally one sees sarcomatous lesions in bone that have all the roentgenographic features of metastasis, but the consensus seems to be that these are multicentric growths. The malignant lymphomas (Hodgkin's disease, lymphosarcoma and leukemia) show involvement of bone in a small proportion of cases. Ewing's tumor also tends to involve the skull in the late stages of the disease.

Two distinct forms of metastatic carcinoma are seen. The osteoclastic (melting or melted ice) form is most frequently seen secondary to carcinoma of the breast; it is the usual form seen secondary to carcinoma of the kidney and genito-urinary tract, suprarenal gland, thyroid gland, bronchus and lung, uterus or adnexa, pancreas and biliary tract. Metastasis from carcinoma of the stomach is rare; when seen it has a distinctive roentgenographic image and shows some tendency to assume the features of the osteoplastic form. Occasionally, a slowly growing carcinoma of the breast will produce an image with some osteoplastic features. The lesions of the osteoclastic forms may be localized or there may be a general involvement of the skeletal structures. One portion of a bone may be

completely destroyed, presenting a perfect picture of a malignant lesion that has produced complete dissolution of the cortical contour. There is seldom evidence of any reaction; the roentgenographic image is that of a complete melting away of the shadow of bone over a limited area. Metastasis is seldom seen in the bones of the extremities below the elbows and the knees; when it does occur there is often almost complete obliteration of the shadow of one or a portion of one of the bones, more frequently of the radius in the forearm and the tibia in the leg. Not infrequently, a faint shadow of the cortex will remain. Lesions in the proximal ends of the femur and humerus are the site of pathologic fracture; not infrequently the pathologic fracture may serve to call attention to the metastatic process and occasionally even to the presence elsewhere in the body of a primary malignancy.

In the spinal column the metastatic process may be confined to a single vertebral body or it may involve several isolated vertebræ. Compression of a vertebral body is noted in some cases in which there is evidence of extensive involvement of other vertebræ but no alteration in their architecture. This suggests that pathologic fracture must be a factor in some of the deformities noted. At necropsy, vertebræ have been examined and proved to be so friable that one could force the finger into the substance of the body but visualization of the lesion in the roentgenogram called for the closest scrutiny. Knowing this, one is justified in upholding a clinical diagnosis of metastasis in the spinal column even when it is impossible to visualize the lesion in the roentgenogram.

Localized lesions in the os innominatum, in the pubis, and in the ischium vary from extensive destruction of bone with irregular, serrated or indistinguishable margins to multiple punctate areas of varying size, or "melted ice" areas of varying dimension.

Localized lesions may occur in the ribs; these are usually multiple lesions scattered throughout several different ribs. Not infrequently, in cases in which patients are of advanced age and there is evidence of some general osteoporosis of bone and a diffuse fibrosis of the lung as a result of chronic bronchitis or other cause, the superimposition of the pulmonary markings on the more translucent bone will give the impression of metastasis in the ribs. In such cases, reëxamination with heavier exposure and the interposition of the Bucky-Potter diaphragm will often reveal normal bone and obviate an error in diagnosis.

In general involvement of most of the skeletal structures, the bone usually will have a honeycombed appearance; the dimension of the individual defects varies widely; punctate areas may be noted in some parts, and there may be a filling defect of varying size in other parts.

The osteoplastic form of metastatic carcinoma is almost always secondary to carcinoma of the prostate gland. The roentgenographic image of this form is that of a background of bony destruction with a concomitant hyperplasia of bone. The one process usually keeps pace with the other, but not infrequently there are variations in the degree of one or the other, with a resultant diversity of the image. In early cases the involvement is in the inner margin of the ilium on one or both sides, under the overlying wing of the sacrum. This may easily be misinterpreted as hypertrophic changes in the sacro-iliac joints. The lesion may involve one pelvic segment before spreading to other parts of the skeleton. In other cases splotches of hyperplasia of bone which are scattered over the shadow of the ilium on one or both sides may be the early evidence of metastasis. These splotches will increase in size and number simultaneously with increasing evidence of destruction of bone, until the entire bony structure of the pelvis and often the upper portion of the femurs are involved. The destruction and the proliferation may coincide to the extent that there may be a homogeneous eburnation, often extending throughout the skeletal structure. In the spinal column, one vertebral body or several separate bodies will be involved; rarely this may be the only evidence of metastatic involvement.

The recognition of the metastatic involvement by roentgenographic examination may be the first intimation of carcinoma of the prostate gland. Occasionally, carcinoma may not be demonstrable by physical examination, even after metastasis in bone has been discovered.

The noninflammatory condition which simulates osteoplastic metastasis is osteitis deformans (Paget's disease). In some cases this may offer considerable difficulty in differential diagnosis. Both diseases affect men who are in the same period of life, and both are frequently incidental findings in routine examinations.

Osteitis deformans may, similarly to carcinomatous osteitis, involve a single pelvic bone before involving the whole skeletal structure; a coincidental secondary anemia is present alike in cases of benign osteitis and carcinomatous osteitis.

In benign osteitis, or osteitis deformans, the evidence of the trabecular elements of the bone is maintained or exaggerated; in carcinomatous osteitis it is always obliterated in cases in which the differential diagnosis is difficult. In osteitis deformans there is an enlargement of the shadow of the bone owing to subperiosteal deposition of osteoid tissue; in carcinomatous osteitis there is no enlargement of the bony shadow. In cases in which the femurs are involved, there is a widening of the cortex and a bowing of the shaft; this feature is absent in carcinomatous osteitis.

Roentgenographic examination of the cranium and the tibia will reveal pathognomonic roentgenographic images if the lesion is osteitis deformans.

Summary

In this necessarily brief review an attempt has been made to point out the salient roentgenographic characteristics of lesions involving bone. In competent hands the roentgenologic method is a rapid and accurate method of determining the etiologic factor in the majority of lesions involving bones and joints. Careful subsequent correlation of the roentgenographic, the clinical and all other findings should be carried out in every case before the ultimate diagnosis is arrived at, and before the therapeutic measures are instituted. Surgical intervention should always be preceded by biopsy under control of a tourniquet, and the decision as to the procedure should always await the results of microscopic examination of the excised tissue. Under such circumstances the roentgenogram is of inestimable value; in fact, one can truly say roentgenology has become one of the indispensable methods in general diagnosis.

THE ROENTGEN TREATMENT OF INFLAMMATORY DISEASES*

GAGE CLEMENT, M.D.
Duluth, Minnesota

IN considering the use of the roentgen ray in the treatment of inflammatory conditions, it must be borne in mind that a whole group of circumstances and developments must be evaluated. One of the first of these is that, until comparatively recently, roentgen rays were used more or less empirically. The instability of the old gas tube, the variation in the quantity and quality of the radiation it produced, the absence of the auto-transformer, the lack of knowledge of filtration as it affects wave-length and depth dose and the entire lack of scientific instruments for measuring roentgen dosage made x-ray therapy, in its early days, more or less unreliable.

Gradually x-ray equipment has been improved. The auto-transformer, the mechanical and valve-tube rectifier, the hot cathode tube, the spectroscope, the electroscope and the r-meter were developed gradually and today are accepted equipment in constant use. These have enabled the radiologist to duplicate, from day to day, the potentials and currents that are needed, and uniform settings and equivalent energies are obtainable at will. Contemporaneously have come methods of studying biological effects and the responses of various types of tissues to ionizing influences. Consequently roentgen therapy has been put upon a sound foundation and must be considered a scientific procedure.

During the development of these various steps in the physical progress of x-ray therapy, radiologists were more and more inclined to concentrate their efforts on the treatment of malignancies and more or less neglect the milder lesions. However, inflammatory lesions have

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1938.

been treated since 1900 and the beneficial effects of the x-ray in acne, furunculosis and erysipelas are well known. Even the recently much-advertised therapy for sinusitis has been used by the radiologist for fifteen years. About eight years ago, Desjardins[2] summarized the results of several years of experience in treating inflammatory conditions and his explanation of the action of the roentgen rays is still authoritative. During this time, also, biophysicists, biochemists and pathologists have been studing the effects of roentgen irradiation on healthy and inflamed tissue. Their observations and recorded findings have brought roentgen therapy into the field of accepted therapeutic agencies.

In applying roentgen irradiation to inflammatory areas the method of application has much to do with the successful outcome of the therapy. It is not sufficient merely to subject the patient to more or less haphazard exposure under an x-ray tube, without giving thought to the invading organisms, the tissues involved or the lymph drainage system of the locality. The nature of the infection, its methods of spreading and the toxic manifestations it produces are important considerations. The depth of the infection in the tissues modifies, to a certain extent, the potential at which the machine is set; the acuteness or chronicity of the lesion indicates the interval of time between treatments; and the probable duration of the disease determines the number of r to be administered at each treatment. As a rule, smaller doses at rather frequent intervals produce better results than larger doses at greater intervals. This has been clearly shown by extensive experimental work carried out in Leningrad. It was noted that the dose-time interval is important. Small doses given every other day had much better effect than larger doses given every fourth day, although the total amount of radiation was the same. This is readily understood when it is realized that only a short time is required to break down the phagocytic cells of the blood, liberating the antibodies or other substances therein contained. These antibodies act as antitoxins and have definite phagocytic properties after liberation. It must be remembered that the metabolism and function of parenchymal and connective tissues are increased by inflammation; therefore, physically equal roentgen doses have much greater effect on inflammatory tissue than on normal tissue.

An editorial in the *Journal of the American Medical Association*[3] reads, in part, as follows: "Roentgen irradiation appears to be capable of aborting many of the early infections and of promoting the breaking down and localization of the more advanced lesions. The roentgen rays are not in themselves bactericidal. The favorable action is believed to be due to the breaking down of certain radio-sensitive cells and the consequent liberation of powerful antitoxic substances."

The amount of irradiation required in the treatment of infections is small as compared with the larger doses ordinarily considered in the treatment of malignant tumors. Surrounding normal tissue is included in the field of application and the lymph drainage areas must certainly be reached. It is advantageous to begin therapy in the lymph drainage areas if possible and then cover the focus of infection. This plan should be followed in such a manner that one area is treated daily, and no time interval of any magnitude intervenes. Kaplan[6] states that "while x-rays are not bactericidal, they possess the power to stimulate within tissues certain responses, as hyperemia and destruction of leukocytes and lymphocytes with the liberation of endotoxins which possess the power of phagocytosis. The employment of x-rays for the treatment of inflammatory conditions is rational procedure."

Time is an important factor in the treatment of infections. Roentgen therapy, in addition to all other kinds or types of therapy selected, should be started early. The most prompt effects and the best results are obtained by early application. It is a well known fact that x-rays increase both the local and general resistance to infection and the tendency toward secondary infection is lessened. This local increase of tissue resistance continues for three or four weeks, after which it gradually declines to normal. It exists only in the area treated and does not extend to adjacent tissues. There is no cumulative action which might lower tissue resistance. Healing takes place normally and neither the diseased tissue nor the healthy tissue surrounding it is injured by the treatment.

It must not be believed that roentgen therapy should be used to the exclusion of any other therapy, neither should it be used as a last resort; it should be considered an adjuvant and be thought of in every infection. Kelley and

Dowell,[7] in an analysis of fifty-six cases of gas bacillus infection, recommend that the patient be treated with x-ray as soon as the presence of the infection is suspected. They believe that such treatment, combined with serum treatment, tetanus antitoxin, local surgical procedures and antiseptics, removes the necessity of amputation. They report a mortality of less than 10 per cent.

In the treatment of lobar pneumonia, Powell[9] gives the results of the treatment of two groups of patients. In both groups the treatment by all other means of therapy remained the same, but one group received the serum and the other group roentgen therapy. In the group which received serum the mortality was 15 per cent, while in the group which received x-ray the mortality was 5 per cent. These statistics agree with those published eleswhere, particularly in Europe, where the mortality rate for all types of pneumonia without serum or x-ray treatment is given as 30 per cent, with serum 15 per cent and with x-ray 5 per cent. These results are due to an early crisis brought about by the x-ray therapy and it is explained by the statement that a certain lysin is liberated from the infiltrating leukocytes which causes rapid solution of the coagulum which is the principal component of the consolidation.

Recent experimental work by Fried[4] on guinea pigs with artificial pneumonia produced by emulsified cultures of hemolytic staphylococcus aureus showed marked consolidations in the control animals while the irradiated animals showed only scattered small areas of consolidation. The irradiated lungs showed less congestion, less edema, less infiltration of tissue and fewer abscess formations.

In substantiation of these findings and results I quote from Boyd[1]: "Acute inflammatory lesions * * * are amenable to radiation. Exposure at an early stage causes rapid resolution. It seems strange that an agent which destroys the inflammatory cells should benefit the lesion. The probable explanation is that protective substances are liberated by the disintegrating polymorphoneuclears and lymphocytes."

The infectious involvements of the nasal accessory sinuses, the mastoids and the middle ear are quite aggravating. After all other medical and surgical procedures have been used and have been found insufficient to relieve the symptoms, a majority of the patients can be benefited by roentgen therapy, provided care in its administration is used. Many exorbitant claims have been made of the results obtained in the treatment of this class of infections and, as a result, some discredit has been reflected on roentgen therapy in all infections. The fact remains, however, that the method of application and not the therapeutic agent itself was at fault. Lucinian[8] reports favorably on the treatment of otitis media and catarrhal deafness, and the works of Woolley[10] and Hodges[5] on sinus infection are well known.

All types of infection have been successfully treated with roentgen rays. These include such conditions as arthritis, parotitis, bursitis, peritonsilar abscess, pyorrhea, endocarditis, bronchiectasis, puerperal mastitis, peritonitis, localized cellulitis, adenitis, endometritis and many others. There is a possibility that any infection may be treated by x-ray if the treatment is administered with caution and the general principles of small doses, repeated frequently, followed. Let me quote from the paper of Desjardins,[2] published seven years ago, whose description of the accepted physiological action of roentgen therapy in inflammation cannot be surpassed. He says: "The infiltrating cells contain or elaborate within themselves the protective substances or other means which enable them to destroy or neutralize the bacterial or other toxic products which give rise to the defensive inflammation. If these assumptions are well founded, it seems not unreasonable to deduce that irradiation, by destroying the infiltrating leukocytes, causes the protective substances contained by such cells to be liberated and to be made even more readily available for defensive purposes than they were in the intact cell."

Founded on such a reasonable premise, the clinical application of the roentgen rays in inflammatory reactions is practicable, efficient and scientific practice.

HISTORY OF MEDICINE IN RAMSEY COUNTY

BY J. M. ARMSTRONG, M.D.

(Continued from November issue)

1853

At the beginning of 1853 there were ten physicians practicing medicine in Saint Paul: Drs. J. H. Day, Goodrich, Barbour, Dewey, Vicchers, Potts, Mann, Brisbine, Babbitt and Willey. David Day was at this time at Long Prairie, and Borup was not practicing.

On March 17, Babbitt's card disappeared from the papers and Dr. Barbour's was discontinued a month later. Whoever was Coroner this year was apparently not filling his office, for on the 20th of April Dr. Mann was appointed by Truman M. Smith, Justice of the Peace, to hold an "inquisition" on the body of a man who met his death by the shifting of a cargo of lumber on one of the river boats. Two more physicians came to Saint Paul: Dr. Wm. H. Morton, of Patterson, N. J., on May 30, and Dr.L. C. Kinney in July. Dr. Kinney stated in his professional announcement that he had been in practice ten years, one of which he spent with the army in Mexico. He took an office in Holland Place, in a two-story frame building that stood on St. Anthony Street opposite the site now occupied by the West Publishing Co.

Dr. Morton seems to have been in no hurry to start in business, for his professional card did not appear in the paper till December 8, when he associated himself with Dr. Potts. They took an office over H. C. Sanford's store situated on Third Street just below Wabasha. Previous to this time Dr. Potts' professional card remained the same as it was in 1849.

This year marks the beginning of medical societies in Minnesota. At this point we must digress a little to settle a point in history which may as well be cleared up now as later.

Our present Minnesota State Medical Association was organized as the Minnesota State Medical Society on February 1, 1869. Its first volume of transactions was published in 1870. This first volume of transactions contains the minutes of the preliminary meeting held for the purpose of organization, a list of those signing the constitution, and the statement that Dr. Thomas R. Potts, president of the old Society organized in 1855, now defunct, presided at the formation of the present Society. In 1925, the Council of our present State Association, finding that the archives of the Association did not have a copy of the first volume, had it reprinted from the only copy available which was and is now in the Library of the Ramsey County Medical Society. As regards the date, 1855, the statement is erroneous, the date should be 1853. The *Pioneer* for July 28, 1853, states:

"In pursuance of a call publically given by the papers of the Territory, physicians representing different counties and towns met in St. Paul on Saturday 23, inst., at the Court House and made a temporary organization, by calling Dr. Potts to the chair and Dr. Anderson Secretary.. The Convention then organized, soon admitted the propriety of forming

a Medical Society, and went into a committee of the whole, Dr. Murphy in the chair, to deliberate upon forming a constitution. At half past twelve the committee rose, to meet at two o'clock at Dr. Mann's office.

"Afternoon Session—The attendance being punctual, the convention resolved itself at once into a committee of the whole, Dr. Murphy in the chair, when a plan of Constitution and By-laws was reported, accepted and the committee discharged, Dr. Potts in the chair. A Constitution made up mainly from those in force in Pennsylvania and Illinois, was now taken up and considered by sections, and with various additions and amendments adopted, together with a set of By-Laws and the American Association's Code of Ethics. Drs. Ames, Murphy, and Mann were now appointed a committee to select permanent officers and committees for the ensuing year: who reported—

"President—Dr. Potts, St. Paul
"Vice Presidents—Drs. Ames, All Saints, and Murphy, St. Anthony
"Corresponding Secretary—Dr. T. T. Mann, St. Paul
"Recording Secretary—Dr. Anderson, St. Anthony."

An abbreviated statement of the proceedings may also be found in the *Northwestern Medical and Surgical Journal* (Chicago) for August, 1853. Corroborating these we find the following from the pen of Dr. Wm. W. Finch, of Saint Paul, in "Physicians, the Climate and Diseases of Minnesota" (*Boston Medical and Surgical Journal,* Oct. 12, 1853):

"On the 23rd of July, 1853, the first Medical Society was organized in this territory and christened 'The Minnesota Medical Society.' Considering that there are scarcely twenty regular physicians in the territory, the meeting was well attended, matters were discussed in a friendly manner and the following officers chosen: Dr. Potts of St. Paul, President; Dr. Ames of Minneapolis, and Dr. Murphy of St. Anthony, Vice Presidents; Dr. Anderson of St. Anthony, Recording Secretary; Dr. Goodrich, Treasurer; Dr. Mann, Corresponding Secretary; and Drs. Day, Dewey, and Finch, Censors. The last five officers are residents of St. Paul. Though few in numbers, we mean to do what we can to sustain and advance medical science in this new territory, and we hope to receive the good wishes at least of the older societies in the states."

If these two citations are not sufficiently convincing that the society was founded in 1853, we find in the Transactions of the American Medical Association of the St. Louis meeting of 1854, that John H. Murphy, Falls of St. Anthony, attended the meeting as a delegate with credentials from the Minnesota Medical Society. Murphy was the first Minnesota physician to belong to the American Medical Association, but while this is true we must state for the benefit of those not informed that Minnesota Territory did not exist until 1849, and just previous to that date the eastern part of our state was part of Wisconsin Territory, and that Dr. A. E. Ames, of Wisconsin, was a member of the American Medical Association in 1848. Ames, however, at that time was not a resident within the present limits of Minnesota. From the *St. Anthony Express,* which contains the best account of this meeting, we learn that Dr. A. E. Johnson of St. Anthony also personally attended the meeting and that Dr. A. W. Daniels of St. Peter and Dr. O. P. Marsh of St. Paul signified their desire to belong and were marked present by request; and that Drs. J. H. Day, A. G. Brisbine and Samuel Willey of St. Paul, together with Dr. Carli of Stillwater and Dr. Chas. McDougall of Fort Snelling, were made charter members, though not actually present. Dr. McDougall had recently arrived at Fort Snelling, relieving Dr. Ames who was Contract Civilian Surgeon there till McDougall arrived. Dr. McDougall, a native of Indiana, entered the army in 1832 and retired in 1869. He was made a Brevet Brigadier General in 1865 for gallant conduct in the field. A meeting of the Society was scheduled for January 1854, but apparently was not held, though it is possible that some data regarding it may yet be found. Mrs. Abbott, widow of the late Dr. Everton J. Abbott and daughter of Dr. John Steele, says she re-

members having a minute book of a medical society and using it for a scrapbook when she was a girl. The book was not destroyed till after Dr. Abbott's death when the family moved to another residence. Possibly, it was the minute book of this Society.

As regards the further activities of this Society, the St. Paul City Directory for 1856-1857 states:

Medical Society of Minnesota—organized December, 1855.
Officers for 1856-7:
Dr. Thomas Potts, President
Dr. J. H. Murphy, Vice President
Dr. J. V. Wren, Recording Secretary
Dr. James D. Goodrich, Corresponding Secretary
Dr. David Day, Treasurer
Dr. W. H. Morton, Dr. F. R. Smith, Dr. J. H. Stewart, Dr. A. E. Johnson, Dr. A. E. Ames—Censors
Dr. R. W. Wing, Dr. O. P. Marsh, Dr. C. L. Anderson—Standing Committee.

Note that the date "1855" appears again. The word "organized" should be "reorganized" at a meeting held in December, 1855. However, the paper for January 5, 1856, says the meeting was held in Dr. Wren's office January 3, 1856, and gives the additional information that Dr. LeBoutillier was chosen essayist. Evidently, this is where the date 1855 came from in the 1869 transactions of our present Association, and also because of no meeting in 1854 a reorganization was effected in 1855. It is known that the Constitution and By-laws of this Society were printed in 1856, but no copy of it has yet been found. The last meeting of the Society was held at St. Anthony in 1857, the officers being the same as given in 1856 with the exception of the censors, who were Drs. W. H. Morton, F. R. Smith, J. H. Stewart, A. E. Johnson, and A. E. Ames. No account of this meeting can be found, the files of St. Anthony and Minneapolis papers being incomplete for that year.

There is evidence then that the Society was active during the years 1853-55-56 and 1857. Our information as to this Society ends here unless further research discloses more data. It will be noted that Dr. Potts was its first and last recorded president. It is probable that the reason Potts was elected president is that he was a much older man than any of the others. In fact, Minnesota at that time was populated chiefly by comparatively young men, and Potts, in 1853, was forty-three years of age and one of the oldest men here. It is further probable that the panic of 1857 killed the Society as it nearly killed all business activities in the Territory. The preceding remarks as to Doctor Potts and the demise of this Society are not founded alone on my own surmises, but Dr. C. E. Smith, Sr., and Dr. Alfred Wharton were of the same opinion. Both of these physicians knew of this Society but had no further recollection of it. St. Paul, in 1850, had a population of 1,294, Ramsey County (then including St. Anthony), 2,197, and the entire territory, excluding soldiers, but 4,780, while in 1860 St. Paul had 10,279 inhabitants and the county 12,150. So the proportion of physicians to the number of inhabitants was excessive, which accounts for the many changes. Every steamboat, however, during this period brought in a cargo of immigrants, speculators, and adventurers.

This same year (1853) Bishop Cretin laid the cornerstone of St. Joseph's Hospital on the same site as the present building, though it was not open to patients till the following year. This was the first hospital in the state other than the military hospitals. It served not only as a hospital but as a home for orphans and the aged and housed the sisters. For some years after 1859 it was

occupied by St. Joseph's Academy. Until our city and county hospital (now the Ancker Hospital) was established in 1882, the city and county patients also were cared for at St. Joseph's.

In July, Dr. Babbitt moved his office from St. Anthony Street to Main Street (West Fourth), between St. Peter and Market Streets. It would seem that ten physicians were not enough for St. Paul, for in July, Dr. O. P. Marsh arrived and took an office on Third Street next to the Post Office (below Wabasha). In October the election returns showed that J. E. Fullerton, Whig nominee for coroner, was victorious over Patric Carey, the Democratic nominee. On November 17, the *Pioneer* published on its editorial page a "Business Directory" of St. Paul and gave the names of fourteen physicians. In addition to those already mentioned the names of Drs. Alfred Berthier, Wm. W. Finch, and David Day were listed. The latter had been physician to the Winnebago Indians at Long Prairie since the spring of 1852. He was still there in 1853, but it was stated in parentheses after his name that "he will take up his residence in St. Paul in the spring." Dr. Day was succeeded at Long Prairie by Dr. Frederick Andros, of Iowa, who had also preceded him in the same position. This same business directory also stated that the druggists in St. Paul were Bond and Kellogg, Wm. W. Hichcox, Wm. H. Jarvis, and John J. Dewey, and that the capital invested in the drug business in our city was $31,000. Kellogg soon went out of business and the firm became Bond and Axtell. At this time there were five physicians in St. Anthony: Drs. J. H. Murphy, A. E. Johnson, Charles L. Anderson, Kingsbury, and Z. Jodon. St. Paul consisted of 700 buildings and 4,700 inhabitants. Although Dr. Finch was in St. Paul before November 17, his professional announcement in the *Pioneer* did not appear till January 5, 1854. It is interesting in its reference to the use of ether.

> "Being familiar with the use of ether, operations in surgery will be performed under its influence without pain, if desired."

The "if desired" seems incomprehensible to us now. Doctor Finch gave as reference Professor McClintock, of the Philadelphia College of Medicine, and Professor Perkins, of Vermont Medical College. Dr. Mann, late in the year, was appointed physician to the Sioux Indians, but retained his residence in St. Paul, since the Sioux were still living at Kaposia (Little Crow's Village). On November 10, Oakland Cemetery was ready for use. Governor Ramsey was president of the Association and Dr. Borup one of the Board of Trustees.

Harry Birmingham, who had been Assistant Surgeon at Fort Snelling for four years, located in St. Paul during the year. He never practiced there, however, but was in the drug business for a time. Dr. Thomas W. Foster, a resident of Hastings, was later a druggist in St. Paul. A son of Dr. Birmingham became a surgeon in the army and died in 1932. Dr. Henry Birmingham died in St. Paul, September 25, 1891. St. Paul, at the end of 1853, had thirty physicians. Three of them never practiced, and Wm. H. Jarvis, as a homeopath, probably did little except counter prescribing at his drug store. A homeopath at that time simply meant that a man bought a book on homeopathy and announced himself as a physician of that cult.

It was during this year that some Chippewa Indians hid under the wooden steps of the Pioneer Building all night in order to waylay any Sioux that might come into town the next morning from Kaposia. Early in the morning of April 27, a canoe containing Old Bets, her sister, and Wooden-legged Jim, her brother, landed at the foot of Jackson Street and the three walked up to the store of the Minnesota Outfit.

It was the intention of the Chippewas to ambush them at the landing, but the marsh between Fifth Street and Third Street prevented them, and the unsuspecting Sioux, circling the flooded area, reached the store before the Chippewas opened fire. Old Bets' sister was mortally wounded, and wooden-legged Jim had a splinter knocked off his wooden leg by a ball as he rushed out of the store to discharge his old pepper-box pistol. Dr. Goodrich dressed the woman's wounds, and at her own request she was taken back to Kaposia, where she died.

Two new life insurance companies entered St. Paul this year: the Mutual Life of New York, for whom Dr. Potts served as medical examiner; and the New England Mutual Life, who employed as examiner Dr. G. S. Sperry. Sometime during the year, Dr. Ebenezer Miller came to St. Paul from Vermont. He was the father of the late Dr. Clinton C. Miller. He never practiced medicine in St. Paul, however, and died in Louisiana, July 21, 1865. Among the distinguished visitors to St. Paul in 1853 was Dr. Marshall Hall of London, famous for his studies of the physiology of the nervous system.

1854

Although most of the physicians who were in St. Paul at the end of 1853 remained there during the following year, the practice of inserting cards in the papers went out of fashion, and the historian is forced to rely upon other sources of information. In February, Dr. Marsh's card disappeared, and a few weeks later advertisements inserted by Dr. Goodrich and Dr. Dewey were discontinued. By the end of the year only three physicians' cards were published in the *Pioneer*; those of Drs. Sperry, Kinney, and J. H. Day. Of these, the last mentioned had left town.

In February, smallpox became epidemic among the Chippewa Indians, and their condition became so bad that the governor appointed Dr. Mann to render medical aid to them. Mann, however, found it inconvenient to leave town and deputed Dr. J. H. Day to act in his place. Day left St. Paul on March 25, and returned sometime in April. He and his guide and interpreter first went to St. Croix Falls and then westward. It was a very arduous trip. The *Pioneer* for May 2 contained a long report made by Dr. Mann to Governor Gorman on the subject. The condition of the Indians was deplorable. Not only were they afflicted with the smallpox; they were destitute as well. In one village, Dr. Day found but seven out of a band of fifty-four alive.

A business directory published in the *Daily Times* for May 16 gave the names of fourteen physicians as follows: Brisbine and Willey, A. Berthier, J. H. Day, J. D. Goodrich, John J. Dewey, C. L. Vicchers, W. W. Finch, David Day, O. P. Marsh, T. T. Mann—Sioux physician, Potts and Morton, and Barbour. In June, Dr. Finch's card was withdrawn from the papers, though he was apparently still in St. Paul as late as October, when he went to Clinton Falls. Early in May the citizens of St. Paul began to be worried by the development of cholera along the river, and a health officer and city physician was appointed. The history of cholera in St. Paul will be discussed in another place.

On June 20, William W. Hichcox, the druggist, who was a man of violent temper, had a dispute with a drayman named Peltier over some drayage charges. As Peltier drove away from the drug store, Hichcox caught up an axe and followed him, running up alongside the cart. Peltier, sitting in the dray, caught up an iron dray pin and swinging it out to ward off the axe, struck Hichcox on the head, fracturing his skull. Hichcox's skull was trephined to raise the depressed bone, but he died on July 3. Charles Bazille, who was coroner at the time, impaneled a jury, and at his order a post-mortem examination was made by Dr.

Morton assisted by Drs. Goodrich, J. H. Day, and Marsh. Peltier was later tried for homicide but was acquitted on the plea of self-defense. Peltier left St. Paul after his acquittal and went to Canada, where he became a monk, a very learned man and teacher. Dr. William G. LeDuc of Hastings witnessed the encounter of the two men. The story of Peltier's later life is recorded from his testimony. It may be of interest to note here that while General LeDuc was attending Harvard Law School in 1849 he was engaged by the *New York Tribune* to report the trial in Boston of Professor Webster, who was charged with the murder of Dr. Parkman.

After Hichcox's death, Dr. David Day, who was appointed administrator of his estate, took over his drug business on the southwest corner of Third and Cedar Streets, and continued it until 1866. In August, a new physician came to town, a Dr. George Hadfield, homeopath. He took an office on Third Street, one door above Buell's store (presumably just below Wabasha). During August, also, Dr. Sperry, who already had been in St. Paul for some time, inserted his professional card in the paper as a "Homeopath, office on Third Street opposite C. E. Mayo and Co.; Residence at Winslow House." Later in the year he changed his announcement, inserting "M.D." after his name, and moved his residence to the Central House (Third and Minnesota Streets). Sperry got into some trouble and left town suddenly about 1859.

Dr. J. H. Day concluded that Kansas and Nebraska territories offered advantages over Minnesota, and in August he left St. Paul and settled at Leavenworth. Dr. L. C. Kinney bought out the World's Fair Drug Store at Third and Robert Streets from William H. Jarvis, and also opened a branch store in upper town at the Winslow Block. At the Democratic primaries in the autumn several candidates sought the nomination for the legislature, among them Drs. Willey and Goodrich. Neither man received the nomination or polled many votes, and both disclaimed any desire for the office—after the election. By a peculiar vote William H. Jarvis was chosen coroner. There were four candidates, H. A. Schlick, Lott Moffet, S. C. Cave, and William H. Jarvis. Jarvis received 342 votes and the other three one vote each. The year 1854 was a banner year for new physicians to locate at St. Paul, more so even than 1851. Among the men to arrive were the following: Thomas J. Vaiden (September 2 or 3), George W. Huntington (October 17), A. E. Boyd, and Louis Francis Tavernier. Dr. Thomas W. Foster, who had been living in Hastings, returned to St. Paul during the year and became actuary and executive for the Oakland Cemetery Association. He and Dr. David Day were also active in the organization of the Board of Trade on November 29. Dr. N. Barbour remained in town and became one of the officials of the Sons of Temperance.

As to Dr. Huntington little further is known. His card was discontinued in November, and he seems to have remained in St. Paul only a short time. Vaiden probably never practiced but interested himself in real estate. He was an elderly man with long dark hair, a gentleman, very reticent as to his affairs, and almost a recluse. More will be said of him later. Boyd remained in town a few years, practicing homeopathy, then moved to a farm in New Canada Township. Later, he came back to St. Paul, where he died June 4, 1888. It is said he knew Dr. Hadfield before coming to St. Paul. Neither he nor Tavernier, however, played any part in the medical history of St. Paul or Ramsey County. Tavernier left to practice at Fort Atkinson, Iowa, for a short time, but returned and died in St. Paul, January 26, 1870, aged fifty-three years. He was a French Canadian. Both Boyd and Tavernier left families in St. Paul.

The Oral Use of Neoprontosil in the Treatment of Chronic Ulcerative Colitis

THE possible efficiency of certain sulfamido compounds in the treatment of chronic ulcerative colitis was foreseen soon after clinical use of these drugs was instituted. This interest in the therapeutic possibilities of these drugs probably was aroused by the fact that these compounds were effective in the treatment of diseases resulting from infection with hemolytic streptococci. It followed, therefore, that some of the sulfamido compounds might be of value in the treatment of chronic ulcerative colitis since this disease may be due to a related organism.

The early experience of Bannick, Brown and Foster, which has been confirmed by Collins and others, seemed to indicate that sulfanilamide was of definite benefit in ulcerative colitis. However, as was pointed out later by Brown, Herrell and Bargen, the occasional appearance of rather severe toxic manifestations subsequent to use of this drug makes the use of sulfanilamide somewhat undesirable. In fact, the general experience of most of those interested in this form of treatment leads, now, to the conclusion that sulfanilamide is not the drug of choice in treatment of this disease. Especially is this true if patients are acutely ill and if there is a rather extensive ulceration of the colon.

In the search for a similar preparation which might possess the therapeutic efficiency of sulfanilamide, without the severe toxic manifestations which prohibit its administration to severely ill patients, neoprontosil was suggested by Bannick and Brown. At that time, however, neoprontosil was available only in a 2.5 per cent solution to be administered parenterally. The inherent chronicity of chronic ulcerative colitis and the necessity of long continued use of any therapeutic agent were somewhat against any parenteral medication. Then too, as was shown by Rosenthal, 85 to 95 per cent of this drug, when given parenterally to experimental animals, was excreted in the urine within five hours. This fact meant that the concentration of the drug could not be held at a high level without repeated injections at short intervals. The experimental work of Raizess and Rosenthal, working independently, indicated that if the drug could be given orally it would be more slowly absorbed and thus would be retained in the body for a longer time. Such retention would allow for greater concentration and, therefore, for greater therapeutic efficiency. Therefore, the material was obtained in powdered (capsule) form and was first administered clinically by Brown, Bannick and Herrell. In a representative group of unselected cases of ulcerative colitis, the results following oral administration of this material were better than the most optimistic expectations.

The dosage employed was similar to that used in the previous oral administration of sulfanilamide. To the average adult, amounts of between

4 and 5 gm. of this drug, divided into five equal parts, were given in each twenty-four hours. In other words, 15 grains (1 gm.) were usually given an hour before each meal, at bedtime, and at 2 a. m. Such a course was administered usually for ten to fourteen days. It seems apparent that if the drug is given an hour before the intake of food, most of the gastro-intestinal symptoms usually associated with sulfamido compounds will be eliminated. Subsequent to a course of this dosage, experience has indicated that a smaller dosage, of approximately 2.5 gm., given daily for another ten to fourteen days, is advisable. Following this again a larger dosage may be employed for at least the first three months of treatment.

In addition to the marked clinical improvement, the lack of toxic manifestations following the use of this drug is apparent. For example, Brown and Herrell reported, following administration of neoprontosil orally to nearly 500 patients, that depression of the leukocyte count was seen only once or twice. It is further interesting that among those individuals with chronic ulcerative colitis, whose stools are rather markedly hemorrhagic and number from four to fifteen per day, both quantity of blood and number of stools are markedly decreased by the third or fourth day of treatment. In other words, blood disappears from the stools of these individuals long before healing of a rather severely denuded bowel would seem possible. It is also interesting that the proctoscopic appearance of the mucous membrane in cases of rather severe ulcerative colitis has been reported to be normal often as early as two or three weeks following administration of neoprontosil. It is proper, however, at this point to emphasize a pertinent observation made by those individuals originally responsible for the administration of this drug in ulcerative colitis; namely, that it is impossible for any chemotherapeutic agent to restore to normal the physiologic function of a bowel which has become contracted and deformed by chronic ulcerative colitis of long standing. If, however, neoprontosil is used early in the course of chronic ulcerative colitis, rather remarkable results may be expected. It is further worthy of emphasis that those who are responsible for the use of neoprontosil have stated repeatedly that they do not pretend to have discovered the cause or the absolute cure of chronic ulcerative colitis; they do feel, however, that continuous use of the drug is amply justified on the basis of clinical experience in the past year.

At present only impressions exist concerning the mode of action of neoprontosil in the treatment of chronic ulcerative colitis. Some general beliefs, however, are justifiable in view of what has been observed clinically and following use of the drug in experiments on animals. Certainly, the therapeutic response cannot be explained on the basis of the sulfanilamide which is made available in the systemic circulation by the breakdown of neoprontosil. In other words, it appears that neoprontosil has an action wholly independent of the available sulfanilamide. Neoprontosil often appears in the stools of human subjects as soon as twelve hours following its oral administration. The clinical results would seem to indicate that at least part of the drug is absorbed through the lower part of the intestinal tract and thereby exerts its efficiency to encourage healing of the mucous membranes. The experimental work of Marshall, however, would tend to indicate that absorption does not take place in the large bowel of experimental animals. This observation, of course, does not necessarily mean that absorption is not possible in the lower part of the intestinal tract of man. It is further possible that the mere presence of the drug in direct contact with the lower part of the bowel may exert a local action independent of that made possible by absorption into mucous membranes or into the systemic circulation.

Certainly, the marked clinical response reported following oral administration of neoprontosil in the treatment of chronic ulcerative colitis is stimulating and it is safe to say that this drug deserves clinical application in an effort to evaluate its efficacy.

Wallace E. Herrell.

Medicine and Music

GREAT musicians have seldom come out of medicine. Fritz Kreisler was a medical student but never graduated. His whole career has been centered in his violin; his medicine was merely a passing incident in his youth, wholly obliterated by his genius in his music.

Theodor Billroth (1829-1884) was a great surgeon and unusually well qualified as a musician. He was a close friend of Brahms and

wrote a classic on the physiology and psychology of music entitled "Wer ist musikalisch?" which was published after his death. While his standing in the musical world did not compare with his fame in surgery he believed that the two were complementary and that the study of music greatly aided his inventive genius as a surgeon. That he had the inherent quality of a real musician is shown in the words he wrote a few hours before his death:

"It is night and everything has been quiet for a long time and now I am very calm. My mind begins to wander. An ethereal blue sky envelops me. My soul soars upwards. The most beautiful harmonies of invisible choirs are audible—in soft undulations like the breath of eternity! I also recognize voices and the gentle whisperings: 'Come, tired man, we will make you happy. In the charm of these spheres we will free you of the thoughts which have been of the greatest joy or deepest sorrow. You have felt yourself as a part of the universe, now be distributed through the universe and comprehend the whole.'"

He died, world-renowned in surgery, but with only local repute as a talented performer and music lover.

Alexander Borodin (1834-87) began his career as a general practitioner but soon dropped it to take up chemistry, in which he became quite eminent, contributing numerous articles to the literature and being credited with being the co-discoverer of aldol, with Wurtz. As a child he had shown marked talent for music and had been given instruction in the piano and cello, in both of which he became proficient. At thirteen he wrote a concerto for the flute. Later he joined the circle of Balakireff, enjoying the companionship of the youthful group which included César Cui, Moussorgsky, Rimsky-Korsakoff and Glazounoff, who laid the foundation of the modern Russian school. Borodin wrote his greatest compositions as recreation in the busiest period of his professional career and two of the best known of these, his third symphony and his opera *Prince Igor,* were unfinished at the time of his death. Both were capably completed by Glazounoff and Rimsky-Korsakoff and are often heard on the programs of the great symphony orchestras. Mr. Ormandy was especially fond of the Polevetzian Dances from *Prince Igor.*

So far as we have been able to discover, Borodin is the only physician in history who attained the highest rank in musical composition.

The one remaining example, and a very remarkable one, is that of Albert Schweitzer, who is still living. Educated originally for the ministry he had also studied organ music under competent teachers and later graduated in medicine. He became the world's foremost exponent of the organ music of J. S. Bach and prepared for publication the most comprehensive and scholarly edition of Bach's preludes and fugues extant. Some years ago he betook himself to the west coast of French Equatorial Africa and established a medical mission at Lambaréne, about seventy miles inland, incidentally building and setting up there a large, modern organ. Wanderers in the dense, almost impassable, forests around there have reported their amazement at hearing the air suddenly filled with the tremendous majesty of a Bach fugue played by a master.

At intervals Schweitzer emerges from his voluntary exile to give organ recitals in London or on the continent. Always he is greeted by large and appreciative crowds of educated musicians who grasp eagerly the opportunity to hear him. He does this to raise money for his mission and he never returns empty-handed.

When one considers the exactions of the musical profession in order to reach the upper strata of perfection it is not surprising that so few have been able to accomplish its highest attainment while at the same time carrying on the work of any kind of medical practice or professional research. Borodin and Schweitzer, one the composer, the other the performer, stand alone in this distinction. G. C.

Typhoid Mary

THE death last month of Typhoid Mary on North Brother Island in the East River, New York, recalls the incident of her detection as a typhoid carrier in 1907.

An outbreak of typhoid fever had occurred in a household at Oyster Bay in the late summer of 1906. In early 1907 Dr. George A. Soper was delegated to trace the source of the infection which involved six of the eleven persons in one household. All six cases had developed in one week's time with no other cases in the neighborhood. After excluding the usual sources of infection, the evidence developed that three weeks before the first case developed a new cook, Mary Mallon, had been employed and had departed three weeks after the typhoid had appeared. When finally located in 1907, she was employed as a cook for a family in New York City and two cases of typhoid fever occurred

in this family. One of the patients, the daughter of the employer, died of the disease. The cook refused to give information as to her past history, but the investigation disclosed that in seven of eight locations where she had been employed in the previous six years typhoid fever had developed a few weeks following her arrival and that she had left in each case a few weeks after the appearance of the disease. She had not contracted the disease at any of the discovered locations. She had been responsible for twenty-six cases with one death and doubtless many more which were not discovered.

Upon her refusal to be examined Typhoid Mary was forcibly taken into custody by the New York Department of Health, not however without a severe struggle. She was taken to the Detention Hospital where repeated examination of the feces proved her to be a typhoid carrier.

It had been shown that the gallbladder is the most frequent harborer of typhoid bacilli in carriers, but Typhoid Mary refused operation. After several years she was released upon promising never to cook again. When this promise was broken she was again placed in detention for life.

It is reported that some two per cent of typhoid patients become carriers with the persistence of the infection in the gallbladder for months or even years following the acute fever. In 1908 Dean reported the case of an English doctor who twenty-nine years before had contracted typhoid fever in America and had had persisting gallbladder symptoms. Although the patient had carried on an active practice, he had not known of a case of typhoid fever for which he might have been responsible.

That a carrier of intestinal infection, especially one of low intelligence, little education and with no sense of responsibility, can be a menace to society was well illustrated in the case of Typhoid Mary. Her refusal to coöperate with authorities indicated a suspicion, at least, on her part that in some way she was responsible for the appearance of typhoid fever wherever she went. Her refusal to part with her gallbladder indicated an unusually long resisting stubbornness.

The American Journal of Medical Jurisprudence

ANOTHER medical journal, the *American Journal of Medical Jurisprudence*, was launched on its career with the appearance of its first number in September, 1938. The tremendous increase in incidents in recent years that result in lawsuits involving medical practice is one of the reasons that such a journal is needed according to the first editorial by the editor, Dr. F. C. Warnshuis. It is believed that such a publication should be invaluable to the medical and dental professions, hospitals, druggist employers, employes, as well as attorneys! Subscription involves joining the American Medico-Legal Association with headquarters in Boston with a five dollar fee for registration and ten dollars annual dues which entitles the member to receive the journal monthly.

A perusal of the first issues of this new journalistic enterprise discloses an interesting array of articles involving various phases of medico-legal matters and the infant journal has our best wishes for a successful future. With the growth of the new journal's advertising section and a reduction in the subscription price we would predict a wider distribution.

A Coördinated Medical and Public Health Program

AT THE meeting of the House of Delegates of the American Medical Association in San Francisco last June a resolution embodying the so-called "Indiana Plan" was submitted.*

The purpose of the plan is the extension of preventive medicine through an active campaign of education not only of the laity but of the medical profession itself. A topic is chosen each month and all agencies of state and county medical societies concentrate on that topic. If, for instance, pneumonia is the subject chosen for January, this subject would be stressed by the Public Health committees of state and county societies before parent teachers or similar associations, or over the radio or in syndicated newspaper articles, and the subject would also be stressed to the profession at county society meetings and in the current issue of the journal.

The plan is being submitted to the county societies by the office of the State Medical Association. If the plan receives a favorable response on the part of the membership, it is safe to say the various committees of the State Medical Association will coöperate wholeheartedly.

*Plan in detail Journal of American Medical Association, 111:49, (July 2) 1938.

A Motivating Force

"Consumption is a very fatal disease as it is at present managed. . . . The nineteenth century is drawing rapidly to a close. It has the honor of having discovered the cause and also of having defined the methods which are capable of exterminating this form of human suffering, and it should not be left to the next century to see them put into execution. From numerous small beginnings this reform will rapidly gain in volume and momentum, and it is destined to sweep with irresistible force over all obstacles, until in every civilized portion of the globe tuberculosis has bowed down to the majesty of preventive medicine."

THUS wrote the late Dr. H. Longstreet Taylor of Minnesota, pioneer leader in the fight against tuberculosis, in the late nineties. However, it did remain for the next century to start the campaign of applying available knowledge to saving lives.

Strangely enough the motivating force was nothing more than a small scrap of paper, the tuberculosis Christmas Seal. This stamp, making every citizen a partner in the crusade, breaks through the wall of public indifference and brings the fight against tuberculosis close to the hearts of the people. It makes possible one of the most far-reaching health educational campaigns of all times. The fatalistic do-nothing attitude toward the great White Plague has given way to hope and action. Participation of citizens makes possible great victories.

Physicians have the aid of an aroused public in their efforts to set up machinery to fight tuberculosis. Sanatoria have made possible the isolation of spreaders of the disease. Intensive educational campaigns using all resources continue to create citizen interest and to disseminate information. The tuberculosis death rate has been halved and almost halved again. Definite programs of prevention and early discovery are in progress.

Of this program, Dr. Irvin Abell, Louisville, Kentucky, president of the American Medical Association, says:

"The splendid results achieved so far in the field of tuberculosis are gratifying, not alone to the profession, but to everyone interested in human welfare. The worthiness of the objective of the Christmas Seal Campaign is such as to appeal to the spirit of human kindness, which should be inherent in every individual, and consequently should have widespread endorsement. The National Tuberculosis Association, judged by its aim and accomplishments, is an institution deserving any and all possible assistance."

The importance of continuing the program is indicated in the following statistics:

Tuberculosis is still the first cause of death during the age period from fifteen to forty-five, although it has been reduced to seventh in importance as a cause of death in the entire population.

There are estimated to be more than 500,000 active cases of tuberculosis in the United States.

It is responsible for the death of 200 people every day, of one individual every seven and one-third minutes. Thirty years ago deaths occurred at the rate of one every three and one-half minutes.

Two-thirds of all the deaths from tuberculosis occur before the age of forty-five.

Considerably more than half of all the deaths from tuberculosis occur during the important productive years of life—between the ages of fifteen and forty-five.

Each year, tuberculosis claims the lives of forty thousand young people between the ages of fifteen and forty-five. In this state, the Minnesota Public Health Association, the affiliated unit of the National Tuberculosis Association, directs the state-wide sale of Christmas Seals.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
W. F. Braasch, M.D., Chairman

THE A.M.A. IS INVESTIGATED

AN ARTICLE which was asserted to have been based on a thorough investigation of the American Medical Association appeared in the November issue of *Fortune*. The first portion includes a concise, if superficial, survey of some of the many activities of the American Medical Association. Unfortunately, the writer did not confine his observation to a thorough, impartial survey of the Association's numerous activities but went on to criticize the recent policies adopted by the Association and wound up with a plea for compulsory health insurance and medical reform. He used the stock arguments long employed by social reformers and included many of the statistical data which appeared in the National Health Report. He repeated the erroneous statement made by many lay observers that the policies of the American Medical Association are dictated by its officers. After all his investigation he failed to find out that the House of Delegates and constituent state societies are the predominant forces in the American Medical Association and not the officers.

Misconceptions

Included among many misconceptions is the appraisal of Doctor Fishbein and his influence on American medicine. Doctor Fishbein is given credit for being the dictator of the policies and opinions of the Association. He is described as a promotor who has "promoted the Association from a mild academic body to a powerful trade association." To those of us who are familiar with conditions existing at the headquarters of the American Medical Association, such statements are ridiculous. According to the author, Doctor Fishbein is guilty of influencing the opinions of the members of the American Medical Association, and of leading their opposition to governmental control of medicine. The author apparently is ignorant of the basic principles of the medical profession when he refers to the practice of medicine as a "Business Government Problem."

The writer states that the policies adopted by the officials of the American Medical Association are generally regarded as being unprogressive and antagonistic to reform. That the officers have been severely criticized by members of the Association and that their future leadership is now seriously threatened. While there may be many who believe this to be true, the great majority of the members of the A.M.A. are largely in agreement with its policies. It must be admitted that the officers of the Association and the Board of Trustees have been conservative in their attitude toward the many radical solutions of the economic problems of medicine which have been proposed in the last few years. If they had not been so, American medicine would be in a thoroughly demoralized state today. The officers have always faithfully carried out the policies adopted by the majority of the members of the House of Delegates and when a reform was suggested which proved to be sound, none were quicker to adopt it and to promote it.

Survey Belittled

The article goes on to belittle the National Survey of Supply of Medical Service, which is being conducted by the physicians themselves. The absurd statement that the physicians cannot estimate the number of patients who have inadequate medical care as accurately as the doorbell surveys conducted by W.P.A. laymen sounds like a direct quotation from one of the medical proponents of medical socialization. References made to the advantages of a panel system of medical care are largely quotations from other superficial surveys made by American observers. The author apparently fails to realize the differences between the social conditions in Europe

and in America; the political control of our governmental activities and its lack of an adequate civil service; the greater demands and the better standards of living among those with low incomes in America—all of which would make a panel system of medical care impossible in this country.

While investigating the American Medical Association the writer apparently had one eye on the activities going on there and the other on the theories of a host of medical social reformers. Instead of a survey of the American Medical Association, the article is just another bit of lay propaganda by another social reformer. Although the writer's arguments for socialization contain nothing new, the veneer of authenticity given by a so-called investigator might well deceive the uninformed.

W. F. Braasch.

TIME TO PUSH FORWARD

Election results and an altered Congress will undoubtedly combine to retard somewhat new welfare programs that require huge expenditures of money.

Legislation to provide for vast new health services will probably be introduced into Congress; but experienced observers are of the opinion that appropriations to finance them will not be so easily secured as formerly.

It is unlikely that any state will seriously consider health legislation before Congress has had time to act.

If, in the meantime, organized medicine pushes forward in its program for local adjustment and improvement where it may be needed, for close and sympathetic coöperation with official agencies and for extension of those services to the needy wherever reliable studies have shown that they are needed, it is unlikely that any radical and unnecessary legislative program will gain support either in Washington or in the state legislatures.

Survey Essential

In any discussions on this issue the first essential will be reliable figures. Failing these, WPA collected figures of the United States Public Health Service's "Doorbell Survey," are sure to be quoted—and believed.

The Survey of Medical Needs and Supply initiated by the American Medical Association and carried on in Minnesota by the Minnesota State Medical Association is designed to supply these figures.

Much information has already been gathered for this study but returns are still far from complete from the physicians themselves.

The importance of complete testimony from the doctors, themselves, has been repeatedly emphasized in these columns. Tabulations of all findings will be made in December. Members who have still not filled in Form No. 1 are urged to do so immediately and send them to the secretaries of their county societies.

ORGANIZED LABOR CONDEMNS SAINT PAUL CITY COUNCIL FIVE DOCTOR PLAN IN ACCIDENT CASES

The Saint Paul Trades and Labor Assembly has emphatically stated that it does not want any part of the plan concocted by Corporation Counsel John W. McConneloug and sponsored by Mayor William H. Fallon to deprive injured St. Paul city employes of their right under the laws of the State of Minnesota to choose their own physician, when injured in line of duty. Without a dissenting vote the Labor Assembly went on record as being opposed to the plan.

The resolution adopted by the Labor Assembly was presented by delegates of the Saint Paul Fire-Fighters' union. It called attention to the fact that the Ramsey County Medical Society had condemned the plan and that "city employes engaged in hazardous occupations are entitled to every protection of medical science." It also pointed out a well known truth "that personal confidence in one's physician is an important element in the treatment of any illness or injury." The resolution concluded by calling "upon the Labor members of the city council to demand a reconsideration of their action and to oppose adoption of any resolution calculated to destroy the right of any city employe to call his family physician for professional care in the event of any illness or injury suffered while in the performance of his official duties."

The Ramsey County Medical Society can well be proud that it took the initiative in condemning the plan and that it has the solid support of the Central Council of Public Service Employes and the Saint Paul Trades and Labor Assembly.

Every member of organized medicine should unite in preserving for these workers, and for themselves, the American principle of free choice of physician. This fight has just commenced and the importance of it will be more apparent as time passes. Right and justice will prevail even though there is a slight delay. Remember! Politicians come, and some politicians go, but the working man and the medical profession will be here for some little time.

HORRIBLE EXAMPLE

In view of the crusading interest shown by many persons outside Washington, D. C., and the government in the welfare of the employes of the Home Owners Loan Corporation, it is particularly interesting to note that Group Health Insurance under the government subsidized plan has encountered nearly all of the difficulties inherent in contract practice during its two years of existence. These difficulties have nothing to do with differences between the association and the District of Columbia Medical Society.

The association started out bravely in 1937 offering full medical and hospital coverage for its members, wives and dependents, whether one or ten, for the sum of $3.30 a month. By the time the first birthday had rolled around, however, all applicants were required to take a physical examination at a cost of $5. If accepted each applicant was obliged to pay a $10 initiation fee for himself and $1 for each dependent in addition to the regular monthly payment. The monthly payment was also increased to $4 a month for a man and his wife and $1 extra for each minor child. There is a prospect, now, that the number of visits by the doctor may have to be minimized by a charge of $1 additional cash for each visit.

At the end of 1937, therefore, the Washington Group Health Association, while serving as the pretext for widespread criticism of the medical profession is rapidly vindicating the attitude of organized medicine toward contract practice.

District of Columbia physicians may be supplied with an invaluable "horrible example" to justify their position. It should assist them materially in their own society-sponsored plans for the aid of low income groups in the capitol.

DENTISTS OPPOSE COMPULSORY CARE

The dentists of the United States joined the doctors in opposition to compulsory health insurance at their 80th annual meeting in St. Louis recently.

The following interesting recommendations by their special committee were adopted by the dental delegates at that meeting:

"We approve of the general expansion of public health services and, in addition, recommend the establishment of a Federal Department of Health with a secretary who shall be a graduate in medicine and a member of the President's Cabinet; and a first secretary who shall be a graduate in dentistry.

"In an expanded public health program which involves a consideration of the expenditure of millions of dollars for public health purposes, your Committee recommends that the problem of dental caries and other dental diseases be included.

"Your committee approves the proposed expansion of maternal and child health services provided that dental care of mothers and children be included.

"In any plan for extension of hospital facilities, your committee recommends that due consideration be given to inclusion of adequate facilities for dental services."

"Satisfactory Care Cannot Be Rendered"

With reference to the proposals for provision of medical care for the medically needy and a general program of medical care the committee made the following recommendations:

"Your committee is convinced that satisfactory dental service cannot be rendered under a compulsory health insurance system. *We therefore do not favor such a plan but do approve voluntary budget plans under professional control which will enable patients to apportion costs and timing of payments so as to reduce the burdens of dental costs and remove the economic barriers which now militate against the receipt of adequate dental care.*

Most Prevalent Disease

"The committee approves the recommendation that such a program should provide for continuing and increased incentives to the development and maintenance of high standards of professional preparation and professional service.

"In view of the fact that dental caries is the most prevalent disease of mankind, the American Dental Association strongly recommends that the Federal Government augment with a comprehensive research program the efforts of the organized dental profession to determine the cause of this disease."

EXPERT MEDICAL TESTIMONY

Malpractice by a physician is predicated on the fact that there has been negligence on the part of such physician, and the size of the verdict awarded the plaintiff must be contingent on the evident results from such negligence. Negligence must be based again on what is proper treatment in the locality in which the injury was alleged to have been sustained and what the average, ordinary and reasonably prudent man would have done in a like situation.

Results in given cases must be sustained or denied by expert testimony. The question is often asked, "What is expert testimony in a malpractice case?"

Expert testimony may or may not be the testimony of a specialist or so-called "expert." It is the opinion of any person qualified by training and education to give such opinion on the facts of the case. This opinion should preferably be given by a qualified practitioner of medicine whose practice is in the same community as the defendant. He is certainly better able to testify as to the usual proceedings in that community than one whose place of business is much removed or who is in a different type of practice.

It has never been the opinion of the Medical Advisory Committee that one practitioner should conceal the facts concerning malpractice by another where negligence is evident. Members of our association should at all times protect each other, however, against the unscrupulous bringing of malpractice suits for the profit to be obtained either from the alleged negligent doctor or his insurance carrier.

In Minnesota the high quality of medical work performed and the evident interest in postgraduate training has given and will give to the people of this state less cause for litigation as time goes on. The year 1938 has shown this to your committee. We have high hopes for the coming year.

WHY DO THEY DELAY?

A significant study of ten years' experience in the Massachusetts Cancer Clinics published recently in the *Journal of the American Medical Association* showed that a large percentage of persons who do not employ a physician fail to do so because they lack proper education rather than because they lack the funds.

Massachusetts has conducted free diagnostic cancer clinics for ten years. Free hospitalization is furnished the indigent and there is low cost hospitalization for those able to pay. Free pathological service is given and, since 1934, education based on the thesis that the local physician shall be instructor and first resource of his community, has been carried on.

Of 3,266 persons with chronic disease whose records indicate need of medical service, 878 did not have a physician during one year preceding the survey.

For every one of these who gave his economic status as a reason for delay 7.47 gave reasons such as fear, no faith in physicians, ignorance of seriousness of the condition, all of which pointed toward need for more information. Among the poor this ratio was reduced to 1 giving economic reasons to 2.46 needing education.

Even in Massachusetts, where economic needs are provided for, the problem of cancer delay is still acute.

THE NEW DESPOTISM

The Lord Chief Justice of England, Lord Hewart, does not contemplate with equanimity the extension of government services in Great Britain. The following quotation from his book is evidence of that.

"In the kind of legislation which is being considered, it is usual to provide that the decision of the Minister shall be final and conclusive. When this is the case, the courts are powerless to intervene, however unjust and absurd a decision may appear to be. . . . It may be said that there is no substantial ground for the fear of unfairness or corruption in the Civil Service. . . . But if there is any great extension of the system of giving uncontrolled and arbitrary powers to public officials, it is as certain as that night follows day that corruption might creep in. We might then be cursed with the corrupt bureaucrat. The bureaucratic despot we already have.

"To take a simple instance, the treatment of panel doctors under the National Health Insurance Acts is pure despotism. The doctors are liable, at the mere discretion of the official who acts for the Minister of Health, to be ruined professionally by being struck off the panel or, as a lesser punishment, to be fined to an arbitrary extent. . . ."

The English Civil Service system is generally believed to be exempt from the distribution of political spoils.

It is doubtful if anyone in the United States could seriously suggest that here there would be no substantial ground for the fear of unfairness or corruption in the Civil Service.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

License of Minneapolis Physician Suspended for Three Years

In the Matter of the Revocation of the License of Samuel R. Fraker, M.D.

The Minnesota State Board of Medical Examiners, at its regular meeting held on November 4, 1938, suspended, for three years, the license to practice medicine and surgery held by Samuel R. Fraker, M.D., Minneapolis. Dr. Fraker admitted his guilt before the Board of a charge of "procuring, aiding and abetting a criminal abortion." Dr. Fraker in his plea that his license be not revoked stated to the Board that he was retiring from the practice of medicine because of ill health.

Dr. Fraker was born in Pennsylvania in 1870 and graduated from the College of Physicians and Surgeons, Baltimore, in 1904.

License of Red Wing Masseur Suspended

In the Matter of the Revocation of the License of Chris J. Bohmbach, Masseur.

Following a hearing held on November 4, 1938, the Minnesota State Board of Medical Examiners suspended, for a period of thirty days, the massage license held by Chris J. Bohmbach, Red Wing, Minnesota.

Mr. Bohmbach was charged with having represented himself to the public as a doctor, chiropractor and other designations whereas the laws of the state limit him to the term masseur. He was also charged with practicing chiropractic without being licensed.

At the hearing Bohmbach stated to the Board that he had removed from his office all signs, diplomas and other placards referring to him as a doctor or chiropractor. Bohmbach had twice previously been warned to remove these signs.

Evidence was also presented that Bohmbach's practice constituted the practice of chiropractic and not massage. He has been warned to keep within the provisions of the massage law or else further action will have to be taken.

Minnesota License of New York Physician Revoked

In the Matter of the Revocation of the License of Norman W. Foster, M.D.

The Minnesota State Board of Medical Examiners on November 4, 1938, revoked the license to practice medicine and surgery held by Norman W. Foster, M.D., of Syracuse, New York. The evidence before the Board showed that Dr. Foster was convicted in the District Court of the United States for the Northern District of New York on October 19, 1937, of violating the Harrison Narcotic Law.

The indictment against Dr. Foster charged him with having sold, bartered, exchanged and given away 13,120 ½ gr. morphine sulphate tablets and 840 ⅓ gr. pantopon tablets to *four* patients during a period of *five* months.

Dr. Foster was born in New York in 1874 and graduated from Syracuse University College of Medicine in 1898. He was licensed in Minnesota by examination in 1898. He resided in Saint Paul before returning to New York. His New York license was revoked in March, 1938.

Hopkins Physician's License Revoked

In the Matter of the Revocation of the License of George W. Moore, M.D.

The license to practice medicine and surgery held by George W. Moore, M.D., Hopkins, Minnesota, was revoked by the Minnesota State Board of Medical Examiners on November 4, 1938. Dr. Moore was found guilty by the Board of "immoral, dishonorable and unprofessional conduct," and specifically with "procuring, aiding and abetting a criminal abortion."

Dr. Moore was before the Medical Board in 1936 on a similar charge and after being reprimanded was placed on probation. The facts show, however, that Dr. Moore continued in this type of criminal practice. Dr. Moore offered no defense at the hearing except to state that he did not "care to discuss the matter."

Dr. Moore was born in Indiana in 1870 and graduated in Medicine from the University of Minnesota in 1892.

Physicians Licensed on November 4, 1938

October Examination

Anderson, John Adolph, U. of Minn., M.B. 1933; M.D. 1934, St. Paul, Minn.
Baker, Theodore, Jr., Jefferson Med. Col., M.D. 1933, Rochester, Minn.
Basom, William Compere, Baylor U., M.D. 1936, Rochester, Minn.
Becker, Arnetta Marie, U. of Minn., M.B. 1937; M.D. 1938, Minneapolis Minn.
Birge, Richard Fuller, U. of Neb., M.D. 1935, Rochester, Minn.
Bodaski, Albert Alexander, U. of Minn., M.B. 1937; M.D. 1938, Minneapolis, Minn.
Bond, John H., U. of Pa., M.D. 1936, Minneapolis, Minn.
Church, John Mark, U. of Chicago, M.D. 1938, St. Paul, Minn.
Cook, Paul Thomas, Northwestern U., M.B. 1937; M.D. 1938, St. Paul, Minn.
Daniel, Ruby Kathryn, Baylor U., M.D. 1928, Rochester, Minn.
Erskine, Gordon McClure, U. of Minn., M.B. 1937; M.D. 1938, Grand Rapids, Minn.
Field, Anthony Hugh, Marquette U., M.D. 1938, Minneapolis, Minn.
Fisk, Charlotte, U. of Iowa, M.D. 1932, Minneapolis, Minn.
Gardner, John Williams, U. of Ore., M.D. 1936, Rochester, Minn.
Grinley, Andrew Victor, Rush Med. Col., M.D. 1937, St. Paul, Minn.
Hammerel, John Joseph, Loyola U., M.D. 1938, St. Paul, Minn.
Henderson, John Warren, U. of Neb., M.D. 1937, Rochester, Minn.
Hertz, Myron Jacob, U. of Minn., M.B. 1938, St. Paul, Minn.
Ide, Lucien Waterman, U. of Iowa, M.D. 1937, St. Paul, Minn.
Karn, Jacob Francis, U. of Minn., M.B. 1938, Minneapolis, Minn.
Kaufmann, Mark Irving Herbert, McGill U., M.D. 1936, Oak Terrace, Minn.
Keating, Francis Raymond, Jr., Cornell U., M.D. 1936, Rochester, Minn.

King, William Lyon Mackenzie, U. of Toronto, M.D. 1937, Rochester, Minn.
Lander, Howard Hayes, Northwestern U., M.D. 1937, Rochester, Minn.
McKelvey, John L., Queen's U., M.D., C.M. 1926, Minneapolis, Minn.
McManamy, Eugene Patrick, McGill U., M.D. 1936, Rochester, Minn.
Morissette, Leopold, U. of Montreal, M.D. 1936, Rochester, Minn.
Mountain, George Elmer, Northwestern U., M.D. 1938, Rochester, Minn.
Nelson, Edward Norman, U. of Cincinnati, M.B. 1938, Minneapolis, Minn.
Novak, Milan Vaclav, U. of Minn., M.B. 1938; M.D. 1938, Minneapolis, Minn.
Peterson, Lowell John, U. of Minn., M.B. 1937, Minneapolis, Minn.
Pugh, David Graham, U. of Ind., M.D. 1932, Rochester, Minn.
Ramsay, Robert Matthews, U. of Manitoba, M.D. 1937, St. Paul, Minn.
Sather, Richard Norman, Rush Med. Col., M.D., 1937, St. Paul, Minn.
Seebach, Leslie G., U. of Minn., M.B. 1938, Minneapolis, Minn.
Sherman, Lloyd Frederick, U. of Minn., M.B. 1938, Minneapolis, Minn.
Sims, John LeRoy, U. of Texas, M.D. 1937, St. Paul, Minn.
Smith, Graham Gable, U. of Minn., M.B. 1938, Minneapolis, Minn.
Smith, Robert Lee, Jr., Stanford U., M.D. 1937, Rochester, Minn.
Stafford, Donald Edward, Harvard U., M.D., 1935, Rochester, Minn.
Stewart, Donald Edward, U. of Minn., M.B. 1937; M.D. 1938, Minneapolis, Minn.
Street, Bernard, U. of Minn., M.B. 1937, Minneapolis, Minn.
Utendorfer, Robert William, Northwestern, M.B. 1937; M.D. 1938, St. Paul, Minn.
Vadheim, James Lowell, U. of Minn., M.B. 1937, Minneapolis, Minn.
Vickers, Evelyn Smith, U. of Minn., M.B. 1936; M.D. 1937, St. Paul, Minn.
Walsh, William Vincent, U. of Minn., M.B. 1937; M.D. 1938, Minneapolis, Minn.
Westra, Jacob John, Rush Med. Col., M.D. 1937; Rochester, Minn.
Word, Harlan Lamar, U. of Okla., M.D. 1936, St. Paul, Minn.
Wulf, Robert Fischer, U. of Pa., M.D., 1936, Rochester, Minn.

By Reciprocity

Baumeister, Carl Frederick, U. of Iowa, M.D. 1933, Council Bluffs, Ia.
Frost, John Bert, U. of Wis., M.D., 1937, Minneapolis, Minn.
Gore, Herbert Robert, Long Island Medical Col., M.D. 1933, Rochester, Minn.
Settlage, Arnold Frederick Ernest, Harvard U., M.D. 1933, Worthington, Minn.
Walske, Benedict Raymond, Marquette U., M.D. 1937, Galesville, Wis.

National Board Credentials

Kenyon, Thomas Jackson, U. of Minn., M.D. 1938, St. Paul, Minn.
Reeser, Richard, Jr., Cornell U., M.D. 1935, Rochester, Minn.
Sundet, Nere Joseph, U. of Minn., M.B. 1936; M.D. 1937, Gary (Norman Co.), Minn.
Vinje, Ralph, Northwestern U., M.D. 1936, Bismarck, N. Dak.

OF GENERAL INTEREST

Dr. Owen W. Parker of Ely was elected president of the Minnesota State Sanitary Conference at its last meeting.

* * *

Dr. H. T. Sherman, formerly of Plainview, has moved to Spring Valley, where he will continue the practice of medicine.

* * *

Dr. Gordon Erskine has become associated with Dr. H. E. Binet, Grand Rapids. Dr. Erskine was formerly located in Minneapolis.

* * *

Dr. James R. Deagen, formerly of Cold Spring, has established an office in Freeport, where he will continue the practice of medicine.

* * *

The engagement has been announced of Eleanor Mary Smith, St. Paul, to Dr. Clarence Dennis, St. Paul, son of Mrs. Warren A. Dennis and the late Dr. Dennis.

* * *

Dr. F. W. Engdahl, formerly associated with Dr. H. E. Binet at Grand Rapids, has moved to Ortonville, where he will continue the practice of medicine.

* * *

Dr. S. Sandell, formerly of Grand Rapids, is taking over the practice of Dr. A. M. Boe of Deer River, who is leaving Deer River because of ill health.

* * *

The Minnesota-Dakota Orthopedic Club met in Rochester on October 22. Several interesting papers were presented in the morning, followed by a luncheon.

* * *

Dr. Traugott Bloedell of Thief River Falls was married to Miss Marion Bernice Long of Minneapolis, on November 9. Dr. Bloedell is on the staff of the Bratrud Clinic.

* * *

Dr. Ralph Vinje of Bismarck, North Dakota, formerly a member of the Roan and Strauss Medical Clinic of Bismarck, has located at Ada for the general practice of medicine. He is a son of Dr. and Mrs. Syver Vinje of Hillsboro, North Dakota.

* * *

Dr. Charles B. Cunningham, obstetrician and gynecologist, has become associated with the Lenon-Peter-

son Clinic in Virginia. Dr. Cunningham was formerly associated with the Harper Hospital at Detroit, Michigan.

* * *

The Minnesota Radiological Society held a meeting in Rochester on October 22. A number of interesting papers were presented in the afternoon. Dr. W. C. MacCarty was the speaker at the informal dinner at the Kahler Hotel.

* * *

Dr. H. W. Arndt of Detroit Lakes has been elected president of a newly organized hospital staff at the St. James Hospital, Perham. Under the new organization no contract surgery will be permitted, it has been announced.

* * *

Dr. O. E. Snyker has located in Virginia for the practice of medicine. He is a graduate of the University of Minnesota and Loyola University of Chicago. He served his internship at Ancker Hospital in Saint Paul, and was house physician at the Midway Hospital in Saint Paul.

* * *

Dr. Robert H. La Bree has succeeded Dr. W. J. Gillesby as resident surgeon at the Rood Hospital in Chisholm. Dr. La Bree is a graduate of the University of Minnesota, and served his internship at the Minneapolis General Hospital. He has also been attending surgeon at the state hospital at Fergus Falls.

* * *

Dr. L. J. Hoyer, formerly of Howard Lake, has moved to Windom. Dr. Hoyer spent most of July, August and September at the Cook County Post Graduate School in Chicago, giving special attention to the subjects of major surgery and fractures. Dr. Hoyer's practice at Howard Lake has been taken over by Dr. R. H. Rolig.

* * *

Dr. Hugh Cabot, consulting surgeon at the Mayo Clinic since 1930, was married at Hingham, Massachusetts, on October 8, to Mrs. Elizabeth Cole Amory. Dr. Cabot left Rochester, September 28, for his former home near Boston, on an indefinite leave of absence, and it is reported he plans to resign his position at the Clinic and live at Hingham.

* * *

Dr. Walter H. Judd, medical missionary from China, son of Dr. E. Starr Judd, has been appearing in a number of educational lectures regarding the United States' relation to China and Japan. He is an effective speaker, and is in a position to know the developments in north China, having been located in North China from 1934 to 1938. Dr. Judd expects to return to China at a later date.

* * *

Dr. F. L. Jennings, assistant superintendent and medical director of Glen Lake Sanatorium, has gone to Indianapolis, Indiana, where he will be superintendent of the Sunnyside Sanatorium. Dr. Jennings was associated with Glen Lake Sanatorium for more than twenty years, and has been a member of the Board of Directors of the Hennepin County Tuberculosis Association, where he has taken an active part in the program for tuberculosis control in Hennepin County.

* * *

Dr. Gilbert J. Thomas has returned from Houston, Texas, where he was a guest speaker at the Seventh Annual Postgraduate Medical Assembly of South Texas, held November 1, 2 and 3. Dr. Thomas spoke on the following subjects: "Non-Specific Renal Infection"; "Chronic Infection of the Prostate Glands; Their Relation to Other Foci of Infection"; "Sterility in the Male and the Responsibility of the General Practitioner in the Diagnosis and Treatment"; "Tuberculosis of the Genital Tract."

Dr. Thomas also spoke to the students at Baylor University by special request, on the subject of "Tuberculosis of the Kidney."

* * *

The detailed plans for the emergency care of visitors to the New York World's Fair include an automobile x-ray unit available to the eight first aid stations to be established on the grounds. X-rays will be taken and developed at once, not only in cases of severe injury, but where fracture is only suspected. It is estimated that such procedure will minimize the fake claims against the Fair itself or exhibitors. First aid in the form of oxygen for resuscitation will also be available in cases of asphyxiation from whatever cause, and inhalation anesthesia for emergency operations. According to estimates, some eighteen to twenty deliveries are likely to take place during the course of the fair.

* * *

The increasing demand for graduate training in the various fields of medicine is evidenced by the following tabulation of the graduate students in the Medical School of the University of Minnesota. This is exclusive of those who are registered under the Mayo Foundation division of the Graduate School.

The total number of candidates for graduate degrees in the fall of 1938 was 166. These are divided as follows:

I. Candidates for Doctor of Philosophy degrees: anatomy, 4; bacteriology, 12; internal medicine, 2; neuropsychiatry, 1; obstetrics and gynecology, 7; ophthalmology and otolaryngology, 1; pediatrics, 6; pharmacology, 3; general physiology, 9; physiological chemistry, 5; general preventive medicine and public health, 1; biostatistics, 1; surgery, 7; and radiology, 5.

II. Candidates for Master's degrees: anatomy, 14; bacteriology, 16; internal medicine, 5; neuropsychiatry, 2; dermatology, 2; ophthalmology and otolaryngology, 12; pathology, 8; pediatrics, 1; pharmacology, 1; general physiology, 12; physiological chemistry, 7; general preventive medicine and public health, 11; biostatistics, 2; surgery, 6; and radiology, 3.

In Memoriam

Leo Melville Crafts

1863-1938

DR. LEO MELVILLE CRAFTS was born in the City of Minneapolis in 1863, the son of Major Amasa and Mary J. Crafts. Some of his ancestors were among the founders of Boston and his parents early pioneers of Minneapolis.

Dr. Crafts was educated in the public schools of Minneapolis and graduated from the law department of the University of Minnesota in 1886 and from Harvard Medical School in 1890. He interned at the Boston City Hospital and also served there for one year as house physician.

He began the practice of his specialty in Minneapolis in the early nineties, serving as professor of Nervous and Mental Diseases in the Medical Department of Hamline University from 1893 to 1908, being Dean of the faculty from 1893 to 1903.

Dr. Crafts was a member of the staffs of most of the leading hospitals in Minneapolis and enjoyed a very large consulting practice. He was treasurer of the Hennepin County Medical Society for two years.

Dr. Crafts belonged to the Hennepin County Medical society, the Minnesota State and American Medical associations, the Massachusetts Medical society, the Harvard Medical and Boston Alumni associations.

He was a member of the First Congregational Church of Minneapolis for fifty-five years, being active in the Minnesota State Sunday School Association, serving as its president for three years. He was a member of the board of directors of the Minnesota National Park and Forestry Association, the old Minneapolis Commercial Club, the Auto Club, the American Legion and the Bloomington Golf Club. He also belonged to the Republican Party, the Sons of the American Revolution, Phi Rho Sigma, and Native Sons of Minnesota.

Dr. Crafts served during the war at Camp Funston and later with the United States Veterans' Bureau at Minneapolis.

On September 4, 1901 he married Amelia I. Burgess, who survives him.

Dr. Crafts practiced neurology in Minneapolis for almost half a century, and was at work in his office when he died on September 22, 1938, at the age of seventy-five.

Dr. Crafts came into the practice of his specialty well prepared. Few men of his time had his educational background. He was a gifted teacher who was able to impart enthusiasm as well as instruction to his students. He personified the highest ideals of medical ethics. As Dean of the medical department of Hamline University he gave a great leadership to his students and to his fellow faculty members as well. Dr. Crafts enjoyed a long and useful practice, being one of the most helpful consultants in his special field.

Dr. Crafts' kindly manner, courteous treatment of others, his ample knowledge and his unlimited charity endeared him to his patients and his fellow doctors.

Following is a list of Dr. Crafts' contributions to medical literature:

1. Relation of Spinal Concussion to Chronic Diseases of the Spinal Cord, 1892.
2. The Sensory Manifestations of Hysteria, 1893.
3. Medical Education, 1898.
4. The Physician in Practice, 1898.
5. A Fifth Case of Family Periodic Paralysis, 1900.
6. Incipient Amyotrophic Lateral Sclerosis with Recovery, 1902.
7. Wear and Care of the Nervous System, 1906.
8. Nerve Stress and Longevity, 1906.
9. The Influence of Ductless Glands Over Metabolism, 1908.
10. Expert Testimony and The Medical Witness, 1909.
11. Mechanism and the Significance of the Reflexes, 1910.
12. The Problem of the Insane and the Defective, 1910.
13. Symptomatology of Traumatic Organic Lesions Affecting Sensorimotor Areas, 1912.
14. Possibilities in the Treatment of Epilepsy, 1915.
15. Myasthenia Gravis with Report of Three Cases, 1917.
16. The Early Recognition of Multiple Sclerosis, 1917.
17. An Original Test for the Pathologic Great Toe Sign, 1919.
18. Mixed Cell Sarcoma of the Brain, 1922.
19. Epidemic Encephalitis: Some of the More Unusual of Its Widely Variant Syndromes, 1923.
20. Text Book on Epidemic Encephalitis, 1927.
21. Reflections on Sexology, 1936.

CLAUDE C. KENNEDY.

Raymond W. Lagerson

1896-1938

DR. RAYMOND W. LAGERSON, a practicing physician in Minneapolis for the past fifteen years, died at the University Hospital, March 13, 1938, following a cerebral hemorrhage.

Dr. Lagerson was born November 19, 1896, at Burns, Minnesota. He graduated from the high school at Anoka in 1915 and received his medical degree from the University of Minnesota Medical School.

A member of the staff of St. Barnabas Hospital for a number of years, he was also a member of the Hennepin County Medical Society, state and national medical associations.

Dr. Lagerson is survived by a daughter, Diane, a brother Leif Lagerson of Milwaukee, and five sisters, Mrs. Joseph Peterson, Mrs. Phil Peterson and Mrs. Earl Hunter of Anoka, Mrs. Frank Addington of Saint Paul, and Mrs. L. H. Nolte of Seattle.

Peter Lorentz Vistaunet

1871-1938

DR. P. L. VISTAUNET, one of the most prominent physicians of Thief River Falls, died on September 22, 1938, from pneumonia.

Dr. Vistaunet was born February 7, 1871, at Inneroi, near Trondhjem, Norway. At the age of seventeen he came to America and received his M.D. degree from the University of Minnesota Medical School in 1902.

On June 27, 1903, Dr. Vistaunet was married to Anna C. Hauglum. His wife and one son, Alv, and daughter, Liv, survive him.

Dr. Vistaunet was city health commissioner for several years. He was a member of the I.O.O.F., W.O.W. and Sons of Norway lodges. An able musician, he served as assistant leader of the Red River Scandinavian Singers' Association and directed the local Brage Chorus for many years. He was choir director in the Trinity Lutheran Church for about twenty years.

MEDICAL BROADCAST FOR DECEMBER

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis (810 kilocycles or 370.2 meters) and Station WLB, University of Minnesota (760 kilocycles or 395 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

December 3—Occupational Skin Disease.
December 10—Tuberculosis.
December 17—Irritable Colon.
December 24—Medical Accomplishments.
December 31—New Year Resolutions.

E. STARR JUDD LECTURE

Dr. Dallas B. Phemister of Chicago, Illinois, Professor and Chairman of the Department of Surgery at the University of Chicago, will give the sixth E. Starr Judd Lecture at the University of Minnesota in the Medical Science Amphitheater on Wednesday, February 1, at 8:15 P. M. The subject of Dr. Phemister's lecture is "Pathogenesis of Gallstones." The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in surgery a few years before his death.

MINNESOTA PUBLIC HEALTH ASSOCIATION

In observance of the twentieth anniversary of the completion of Minnesota's chain of public tuberculosis sanatoria, the Minnesota Public Health Association dedicated its annual meeting, held November 18, in the Twin Cities, to the surviving original board members of each institution. Principal speakers were Dr. W. W. Bauer, Director of the Bureau of Health and Public Instruction of the American Medical Association, Chicago, and Dr. H. E. Hilleboe, Director, Divisions of Tuberculosis and Services for Crippled Children, Minnesota State Board of Control.

Dr. S. A. Slater, Worthington, President of the Association, presented the following pioneer sanatorium board members with life certificates in the organization: Dr. E. L. Tuohy, Duluth, of Nopeming Sanatorium, St. Louis County, the first county institution in the state, established in 1912; Mrs. W. J. O'Toole, Mrs. L. P. Wolff, Mrs. Claude S. Brown and Mr. James C. Otis, all of St. Paul, Ramsey County Preventorium established in 1915; Mr. L. E. Johnson, Wanamingo, and Mr. M. W. Smith of Red Wing, Mineral Springs Sanatorium established in 1915; Mr. Edward C. Gale and Mr. Joseph R. Kingman, Minneapolis, of Glen Lake Sanatorium, established in 1916; Mr. J. L. Wold, Thief River Falls, of Sunnyrest Sanatorium, established in 1916; Dr. E. W. Johnson, Mr. A. P. Ritchie and Mr. A. A. Tone, all of Bemidji, Lake Julia Sanatorium, established in 1916; Dr. C. L. Sherman, Luverne, Dr. A. L. Vadheim, Tyler, L. F. Johnson, Mankato, Dr. Thomas Lowe, Pipestone, G. S. Redmond, Pipestone, N. P. Minion, Bingham Lake, H. M. Burnham, Jackson, S. S. Smith, Worthington, of Southwestern Minnesota Sanatorium, established in 1917; Mr. E. W. Davis, Detroit Lakes, Dr. O. J. Hagen, Moorhead, Mr. John Nelson, Lake Park, of Sand Beach Sanatorium, established in 1917; Mr. L. Engstrom, Roseau, Donald Robertson, Argyle, and Dr. O. F. Mellby, Thief River Falls, of Oakland Park Sanatorium, established in 1918; Dr. W. W. Will, Bertha, of Fair Oaks Lodge Sanatorium, established in 1918; Dr. J. A. Thabes, Brainerd, Charles P. Delaittre, Aitkin, and Mr. Peter Larson, Aitkin, of Deerwood Sanatorium, established in 1918.

Dr. Hilleboe summarized the progress made in Minnesota during its sanatorium and anti-tuberculosis campaign and the problem ahead in the following words:

"Since the establishment of Pokegama Sanatorium at Pokegama, Minnesota, in 1905, and the Minnesota State Sanatorium at Ah-Gwah-Ching, Minnesota, in 1907, with the capacity of sixty beds, farsighted county and state officials, public spirited citizens, and physicians have continued to develop the sanatorium program with the result that at the present time there are fourteen county sanatoria, one county preventorium, and one state sanatorium, with the total capacity of 2,254 beds available for the care of the tuberculous. In 1937 there were 912 deaths from tuberculosis. This means that there are more than two sanatorium beds available for each death from tuberculosis in any one year in Minnesota at the present time.

"With the establishment of adequate sanatoria beds for care of tuberculous patients in need of hospitalization, our program is being directed in two other fields of endeavor. First, it is essential for control of the disease to diagnose early cases of tuberculosis so that the best possible chance of arrest of the disease may be obtained. After an adequate period of sanatorium care, another important factor in the control of tuberculosis is being developed in after-care and rehabilitation of tuberculous patients. It is necessary to provide the necessities of life, medical supervision, and relief from mental anxiety for tuberculous patients discharged from sanatoria, particularly during the first five years after discharge, if best results are to be obtained. The needs of the tuberculous in Minnesota can be met only if a strong battle is waged against this dread disease along these three fronts."

CAMP RELEASE DISTRICT

At the meeting of the Camp Release District Medical Society, held on October 20, 1938, the following officers were elected for the coming year: H. A. Roust, Montevideo, president; George Tangen, Canby, vice president; Magnus Westby, Madison, secretary-treasurer.

The following members were elected to the Advisory Committee: M. Hauge, Clarkfield; George Boody, Jr., Dawson; F. M. Burns, Milan; H. L. Herbert, Granite Falls; N. Westby, Madison; L. G. Smith, Montevideo.

The society held a meeting at Montevideo on November 3. Dr. Frederick H. K. Schaaf of Minneapolis spoke on "Cardiac Disorders."

EAST CENTRAL MINNESOTA

The East Central Minnesota Medical Society held a dinner and inter-professional meeting at the Episcopal Parish House in Anoka, Minnesota, on October 11, 1938. Problems common to the allied professions of medicine, law, dentistry, and pharmacy were discussed by guest speakers.

Guests of the Society were Dr. Wm. Dickson of Minneapolis, Vice-Chairman of the Legislative Committee of the State Dental Association; Dr. B. J. Branton, Willmar; Mr. H. H. Gregg, Minneapolis; Dr. F. J. Savage, St. Paul; and Mr. R. R. Rosell, Executive Secretary of the State Medical Association.

MOWER COUNTY

Newly elected officers of the Mower County Medical Society are: R. S. Hegge, Austin, president; J. M. Thomson, Brownsdale, vice president; Paul A. Robertson, Austin, secretary; A. E. Henslin, Le Roy, treasurer.

RICE COUNTY

At the meeting of the Rice County Medical Society, held in Faribault, November 3, Dr. Gordon R. Kamman of Saint Paul was the guest speaker. His subject was "Endemic Encephalitis."

SOUTHWESTERN MINNESOTA

The annual meeting of the Southwestern Minnesota Medical Society was held in Worthington on October 31. Doctors from six counties gathered for dinner and heard Dr. William A. O'Brien speak on "Socialized Medicine." Dr. J. D. Waller of Wilmont was elected president; Dr. B. M. Stephenson of Fulda, vice president; Dr. J. De Boer of Edgerton, secretary-treasurer; Dr. E. W. Arnold of Adrian, censor from Nobles County.

The members of the Woman's Auxiliary of the Society were present at the dinner, and were entertained afterward by Mrs. C. R. Stanley.

STEARNS-BENTON COUNTIES

The Stearns-Benton Medical Society held its monthly meeting in St. Cloud on November 17. Dr. W. W. Bill of Bertha, and Dr. E. J. Simons of Swanville, were the principal speakers.

WOMAN'S AUXILIARY

Mrs. W. B. Roberts, President
2735 Irving Avenue South, Minneapolis.
Mrs. E. V. Goltz, Press and Publicity, St. Paul, Minn.

The members of the Women's Auxiliary of the Hennepin County Medical Society, held their regular meeting Friday, November 4, in the Hennepin County Medical Library. On November 18 and 19 they sponsored the annual sale of articles made by the patients of Glen Lake Sanatorium, the proceeds going to the makers of the articles. The sale was under the leadership of Mrs. J. C. Davis, chairman, and Mmes. N. F. Lufkin, L. F. Richdorf, J. C. Miller, L. M. Larson, F. L. Jennings and Donald McCarthy.

* * *

The members of the Women's Auxiliary of the Scott Carver Medical Society held their first meeting of the season on October 11 at Montgomery, Minnesota. After having dinner with their husbands they met at the home of Mrs. Alvin Westerman and discussed plans for the year. The new officers are: Mrs. B. F. Pearson, Shakopee, president; Mrs. H. P. Fischer, Shakopee, vice president; Mrs. H. M. Juergins, Belle Plaine, secretary and treasurer.

* * *

The members of the Ramsey County Auxiliary held their first meeting of the fall in the Medical Society rooms in the Lowry Building, Monday, October 24. Mrs. A. E. Nichols, president, presided. During the afternoon a reading was given by Mrs. Roy Jones of Minneapolis. Members of the board for the coming year are: Mrs. A. E. Nichols, President; Mrs. Harry Ghent, president-elect; Mrs. Hugh Beals, vice president; Mrs. Charles Waas, recording secretary; Mrs. Mark Ryan, treasurer; Mrs. E. H. Boland, auditor; Mrs. E. C. Eshelby, parliamentarian; Mrs. Albert Schulze, historian; Mrs. B. J. Mears, magazine; Mrs. Herman Kesting, information; Mrs. Richard Aurelius, Christmas seals; Mrs. C. Neumann McCloud, hospitality; Mrs. Karl Wold, philanthropic; Mrs. Lloyd G. Dack, program; Mrs. Douglas Brand, year book; Mrs. Gordon R. Kamman, publicity; and Mrs. James Benepe, ways and means.

* * *

Mrs. Wm. B. Roberts, president of the Women's Auxiliary of the Minnesota State Medical Association, returned November 13 from an extensive trip in the East.

Oddities Called for in Drug Stores

Sterilized Ink for Stearate of Zinc.
Hyena Nursing Bottle for Hygeia Bottle.
Paralyzed Gauze for Sterilized Gauze.
Aspiration Tablets for Aspirin Tablets.
Polluted Water for Pluto Water.
Scott's Emotion for Scott's Emulsion.
Rooster Foam for Hennafoam.
Runaway Seeds for Caraway Seeds.
Cynical for Clinical Thermometer.
Exorbitant for Absorbent Cotton.

Meeting of October 12, 1938.

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 12, 1938. Dinner was served at 7 o'clock and the meeting was called to order at 8 o'clock by the President, Dr. R. T. LaVake.

There were fifty-six members and one guest present.

Minutes of the May meeting were read and approved as read.

The Secretary read a letter of resignation from Dr. George E. Senkler, with the recommendation from the Executive Committee that his name be placed on the Honorary Membership list. A motion was seconded and unanimously carried that this be done.

The Secretary introduced a proposed amendment to Article III, Section I of the Constitution to read as follows: "There may also be *ten* active members from the University faculty who are teachers of medicine not engaged in private practice." This had been approved by the Executive Committee and will be printed on the November programs. The Executive Committee also suggested the election of new members at the December meeting.

The Secretary was instructed to write a letter of appreciation to Dr. Archa Wilcox for the party held at Dr. Wilcox's summer home in July.

The scientific program followed.

PRIMARY CARCINOMA OF THE PANCREAS

Justus Ohage, M.D.

Dr. Ohage, of St. Paul, read his Inaugural Thesis on the above subject. (To appear in Minnesota Medicine at a later date.)

Abstract

A series of thirty-nine cases of primary carcinoma of the pancreas, proved by autopsy or operation, were reviewed.

Primary carcinoma of the pancreas is most common in the fifth and sixth decades; the average age of incidence in this series was sixty-one years. It is more common in males than in females; the ratio in this series was 2.5 to 1. The head of the pancreas is most commonly involved; only the head was involved in almost 60 per cent of the cases in this series.

The diagnosis of primary carcinoma of the pancreas is largely by exclusion. Most commonly it must be differentiated from stone in the common duct. For this purpose, the Watson test is very useful.

Negative x-ray findings in the stomach and duodenum are also of great value as diagnostic aids.

Jaundice should not be considered as a cardinal symptom. At least four, and possibly seven, cases in this series had no jaundice and no involvement of the common duct.

The prognosis is grave but by no means hopeless. Surgical intervention is the best palliative means. Cholecystoduodenostomy and cholescystojejunostomy are the operations of choice.

Discussion

Dr. Irvine McQuarrie (U. of M.): Do these malignant tumors ever originate from the Islands of Langerhans?

Dr. Ohage: Very rarely. Malignant tumors of the pancreas nearly always originate from the ducts of the gland or the parenchyma.

Dr. Max Hoffman (St. Paul): Dr. Ohage stated that five of the cases presented showed positive blood findings in the stool. I am impressed with the fact that in carcinoma of the head of the pancreas blood is frequently found in the stool, and it is a valuable diagnostic finding. I would like to ask Dr. Ohage if stools were examined in the entire series? Contrary to the textbook description of carcinoma of the head of the pancreas, intermittent jaundice is not rare, especially in the early states, and the presence of intermittent jaundice should not lead one away from the true diagnosis.

Dr. Ohage: Unfortunately, all of our cases did not have stool analysis and consequently I was unable to determine the exact percentage of cases which showed blood in the stool. In our series, five cases showed blood and absence of bile.

Dr. Moses Barron (Minneapolis): Dr. Ohage stated that jaundice is not a constant finding in his series of cases. However, it is obvious that the jaundice is important in diagnosing carcinoma of the pancreas only when the tumor is in the region of the head of the organ. In a number of his cases the involvement was in the body and tail, and of course jaundice is of little importance when in these regions. Dr. Hoffman brought out the fact that occasionally there is an intermittency in the jaundice. That is true. Occasionally there develops collateral inflammatory edema as a result of the growth of these tumors. When the edema is present the bile ducts may be compressed, with jaundice resulting. When the edema subsides the ducts may reopen, and the jaundice may disappear. One cannot say dogmatically that because there is intermittency the jaundice is not the result of a tumor in the head of the pancreas.

Dr. Henry L. Ulrich (Minneapolis): I recall a case of carcinoma of the tail of the pancreas. All the symptoms were pleural. There were repeated effusions in the left chest which, as they progressed, became more and more mucoid in character. Not until the postmortem did we realize what we were dealing with. A primary carcinoma of the tail had walked up through the spleen and then the diaphragm and had involved the left pleura.

Dr. Ohage: In answer to Dr. Barron's discussion,

jaundice is practically always present in carcinoma of the head of the pancreas except in anomalous conditions, as in one case where the common duct passed completely over the head of the pancreas. If there is no involvement of the common duct by compression or extension of the malignant process, jaundice does not take place. Dr. Ulrich cited a case of carcinoma of the tail of the pancreas in which case the malignancy extended through the diaphragm into the lung. The patient showed no jaundice.

NAILING OF HIP FRACTURES

Wallace Cole, M.D.

Dr. Cole, of St. Paul, reported on this method of operation in hip fractures, and showed lantern slides.

Discussion

Dr. E. A. Regnier (Minneapolis): I wish to compliment Dr. Cole on this report of his method of nailing intracapsular hip fractures. Those of us who have taken an interest in this type of work have been bewildered by the numerous gadgets which have been devised. I have had the opportunity of seeing Dr. Cole's instrument used by his colleagues and I am frank to state that it is the best that I have seen.

While the conservative method of treatment recommended by Whitman is still usable and good in well-trained hands, I believe that the day is not far away when all these intracapsular fractures will be treated immediately by internal fixation. We now have evidence that the treatment by internal fixation will be attended by a high percentage of excellent results.

There are three or four factors, as Dr. Cole has stated, which recommend internal fixation. The first and most important of these is the immediate relief of pain, doing away with long periods of bed rest and sedation by the use of opiates. The second factor is the great economic saving to the patient both in money and period of disability. The third factor is that it obviates a prolonged period of rehabilitation of the patient due to prolonged incarceration in plaster. All these factors, assuming that an accurate reduction was obtained and the fixation was maintained, insure a bony union.

I have had a limited experience in nailing hip fractures by the direct exposure method. I have, in most instances, chosen to nail them by driving a nail over a previously inserted Kirschner wire. This method is just as satisfactory as the former, provided that ample radiographic studies are made to assure the operator of a careful reduction and an optimum position for the insertion of the nail. I think that Dr. Cole will agree that an accurate reduction of these fractures even by the open method is often very difficult. Again I wish to state that this instrument devised by Dr. Cole is unique in the versatility of its application and, if used according to instructions, is practically fool-proof.

The meeting adjourned.

A. G. Schulze, M.D.
Secretary.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

Our Common Ailment. Constipation and Its Cause and Cure. Harold Aaron, M.D., Medical Consultant to Consumers Union of United States. 192 pages. Price, cloth, $1.50. New York: Dodge Publishing Co., 1938.

The 1938 Year Book of General Medicine. Edited by George F. Dick, M.D., et al. 840 pages. Illus. Price, cloth, $3.00. Chicago: Year Book Publishers, 1938.

Doctor Bradley Remembers. A Novel. Francis Brett Young. 522 pages. Price, cloth, $2.75. New York: Reynal & Hitchcock, 1938.

How to Conquer Constipation. J. F. Montague, M.D., Editor-in-Chief of Health Digest. Medical Director New York Intestinal Sanitarium, etc. 244 pages. Price, cloth, $1.50. Philadelphia: J. B. Lippincott Co., 1938.

CRIPPLED CHILDREN: THEIR TREATMENT AND ORTHOPEDIC NURSING. Earl D. McBride and Winifred R. Sink. 379 Pages. Illus. Cloth, $3.50. 2d edition. St. Louis: Mosby, 1937.

This book deals with the various phases of the handling of crippled children. It is intended for the training of nurses but contains more inaccuracies and dogmatic statements than one would expect in a text used for instruction purposes. The language has been simplified to such an extreme extent that the value of the work as a reference is lost. The illustrations for the most part are fairly good but do not, in all cases, adequately picture the condition under discussion.

The advisability of using such a book as this for distribution to social workers and the laity is questioned.

THE HORSE AND BUGGY DOCTOR by Arthur E. Hertzler, M.D. New York. Harper Bros. 1938.

The story of the early experiences of a small town doctor in the horse and buggy days, his difficulties in transportation and the establishment of a hospital, is written in a most entertaining style and so saturated with humor and horse sense that the book is being enjoyed not only by doctors but by the general public. A book of this sort, which should prove to be one of the best sellers, will do much to emphasize the importance of the personal relationship between patient and doctor, so essential to the best medical care.

MINNEAPOLIS SURGICAL SOCIETY

Stated Meeting, Thursday, October 6, 1938

A PRELIMINARY REPORT ON THE INFLUENCE OF FOOD AND FUNCTION ON THE INCIDENCE OF MAMMARY GLAND TUMOR IN "A" STOCK ALBINO MICE*

IVAR SIVERTSEN, M.D.
AND
WALDON H. HASTINGS, M.S.

Minneapolis

SEVENTEEN years ago[6] a preliminary report was compiled on the relationship of muscular activity to carcinoma in man. In this paper it was suggested that the lack of muscular activity may be a definite factor in the causation of or susceptibility to cancer. When the adult males in Minnesota who died during the years 1918, 1919 and 1920 were divided into six groups according to the degree of muscular activity demanded by their occupations, it was found that the ratio of cancer incidence between the most physically active and the least physically active group was one to twelve.

During the ensuing years the exigencies of private practice have delayed a scientific study of this interesting disclosure. January 1, 1937, marked a new era and studies were resumed, this time with experimental animals. Because of the present difficulty in using controlled human subjects it was decided to secure pure strain mice having a high incidence of carcinoma for experimental work. The studies on these animals which I should like to discuss this evening resulted from the following observations: (1) the cancer death rate in males actively engaged in a gainful occupation is less than the death rate of those not actively engaged in a gainful occupation and is inversely proportional to the degree of muscular activity necessary for that occupation; (2) there appears to be a recent increase in cancer accompanying the advent of the age of machinery; (3) cancer has been recognized as a degenerative disease, and, knowing that degeneration takes place in all tissue that does not function, it is thought that food and function must be factors in maintaining a normal physiological condition of the human body.

History.—It is a general clinical observation that neoplastic tissue can proliferate in spite of unfavorable dietary and metabolic conditions. However, when these factors are carefully controlled their influence is seen on tumor growth.

Ball and Samuels[1] report a profound depression in the rate of growth of the Walker rat carcinoma 265 and a decrease in the number of positive growths on implantation, following the removal of the pituitary. Voegtlin and Thompson,[9] using the Marsh strain of mice, found that tumorous animals fed a diet deficient in the essential amino-acid lysine showed striking inhibition of tumor growth. Maison and Pourbaix[4] found that feeding organs and extracts of organs had in some cases an acceleratory effect and in others an inhibiting effect on the growth of tar cancers in mice.

Sugiura and Benedict[8] have studied the influence of insufficient diets on tumor recurrence and growth in rats and mice. They found that transplants of the Flexner-Jobling rat carcinoma in rats fed a complete basic diet but limited in quantity to one-third that of the normal food requirement, survived less frequently and grew much more slowly than those in full-fed controls; that under-feeding, after engrafted tumors had well established themselves in the hosts, had no marked inhibitory effect on the subsequent rate of tumor growth; and that prolonged post-operative insufficient feeding had a distinct influence on the frequency of recurrences of spontaneous tumors in mice. Using 65 mice carrying spontaneous tumor they found that 73% of those under-fed were completely cured of the tumors, while on the other hand 18% of the normally-fed controls were free from tumor at the time of death. The average post-operative longevity in the under-fed mice was 142 days against 96 days for the full-fed controls. The gain of 46 days in the experimental animals corresponds to about 3.8 years of a man's life. In addition, the number of metastases found at autopsy was much less in the under-fed animals than in the full-fed controls.

Some studies have been made by Strong and Bittner on the "A" strain albino mice, inbred since 1912 and originally secured from H. G. Bagg. Strong[7] found that 90% of the breeding females of this stock had spontaneous mammary gland cancer. The average age of the tumorous mice varied significantly when different diets were fed. He also found that "A" strain mice kept on the same diet in New Haven, Connecticut, Bar Barbor, Maine, and Ann Arbor, Michigan, give the same age distribution of spontaneous tumor of the mammary gland. Bittner reports on 292 "A" strain mice, of which 88% of those living after four months developed mammary gland carcinoma at an average age of 11.5 months or 350 days. These mice were fed Purina Fox Chow food ad libitum. About 68 per cent of 421 mice were cancerous at an average age of nine months when fed rolled oats, milk and salt. The increase in the percentage of tumors and the increase in the average age at the onset of the tumor in the mice on the Fox Chow diet was attributed to the better health of the animals, allowing more to live into the cancerous age.

Bittner concludes in this paper that, "Given the cancer susceptibility constitution and the subsequent irritating factors, the average age at the appearance of mammary gland tumors may possibly be influenced by the physical condition of the individual."

Experiments.—In view of the promising effects of these simple dietary experiments, twenty-six "A" stock

*From the Sivertsen Clinic (Sivertsen) and the Department of Physiology, University of Minnesota Medical School (Hastings).

mice were secured from Dr. Bittner, Jackson Memorial Laboratory, for a preliminary study on dietary and metabolic factors influencing tumor incidence. These mice normally have an incidence of 88 per cent spontaneous mammary gland tumors at an average age of 11.5 months.

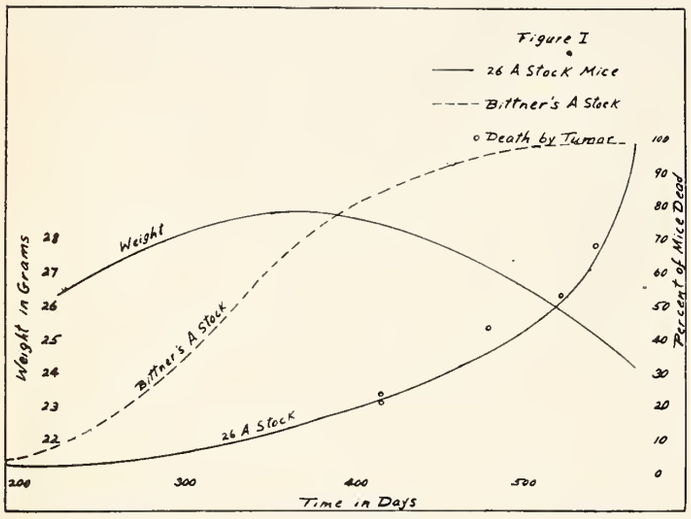

Fig. 1. Percentage of mice dead in the two "A" strain colonies and the average weight of the mice used in this experiment.

The animals were housed in wooden boxes, fed Purina Fox Chow food, and in every way possible were kept under the same conditions as other "A" stock mice reported in the literature. They were mated and produced one to three litters of young each. As Murray[5] and Bittner[3] have found no correlation between the average tumor age for animals and their breeding records, the males were removed from the colony after nine months. The only variables between this colony and Bittner's were the amount of a complete basic diet given per day and the amount of exercise.

To find the amount of food which the mice needed to maintain their weight equal to controls fed ad libitum, fourteen contemporary mice were chosen for a feeding experiment. At the beginning of the experiment Group I, consisting of seven mice, weighed an average of 27.13 grams. Group II, also seven mice, weighed an average of 27.81 grams. Group II mice fed ad libitum for eighteen days consumed 3.76 grams per day and weighed 27.83 grams at the end of that period. Group I mice were fed only enough to maintain their weight constant with those of Group II and consumed 1.94 grams per day. These mice weighed 27.16 grams at the end of the eighteen day period. Thus it was shown that mice fed ad libitum eat twice as much as is necessary to keep their weight constant. From time to time as the mice grew older this experiment was repeated and the diet of the "A" stock experimental animals was varied to meet the requirements of weight equal to mice fed ad libitum.

In addition to the restricted diet a large circular cage was constructed in which the mice were exercised daily

TABLE I.—NUMBER OF MICE DYING CANCEROUS AND NON-CANCEROUS, AVERAGE WEIGHT AND FOOD CONSUMED PER DAY BY EACH, IN MONTHLY PERIODS.

Age in months	No. dying non-cancerous	No. dying cancerous	Weight in grams (Average)	Food consumer grams per day
6.5	1		24.5	2
8.5			26.0	
10.5	1		28.0	2.5
12.5	2		28.0	3
13.5	2		28.0	3
14.5	2	2	26.5	
15.5	1		28.5	
16.5	1	1	27.0	
17.5		1	26.0	3
18.5	2	1	26.0	
19.5	9		25.0	3

for two hours. This exercising period was strictly supervised by a technician.

Results.—The results of our experiment are presented in Table I and Figure 1. Dr. Bittner's 292 mice fed Fox Chow ad libitum lived 358±8.1 days. Our mice lived 482±6.4 days. Two hundred and fifty-seven of Bittner's mice developed mammary gland cancer at an average of 351±3.6 days. Four of our twenty-six mice died of mammary gland cancer at an average age of 463±2.3 days. One of our mice died of primary lung tumor when 550 days old.

As our group of four mammary gland cancerous mice is quite small for significant comparison with Bittner's group we will take his group as standard and see what the chance is that four mice drawn at random from his group dying cancerous will live for an average age of 463 days. This probability is 0.00007, which means that the chances are seven in 100,000 that our four mice dying of cancer could be taken from Bittner's group. It is thus significant that the age at which our cancerous mice died was probably greatly increased by the conditions under which they existed.

In Bittner's group, twenty-four mice lived beyond 463 days. Of these, twenty-one died of cancer. In our experiment fifteen mice lived beyond 463 days, two developed mammary gland cancer and one lung cancer. This shows that the incidence of cancer has been decreased in mice living into the fatal cancerous age.

Conclusions

The incidence of mammary gland carcinoma in "A" strain albino mice has been decreased from 88 per cent to 16 per cent in the animals studied in this experiment. The average age at which these 16 per cent develop cancer has been significantly increased beyond the average age of Bittner's colony.

It is indicated from this experiment that further work should be done using larger numbers of animals. The nature of this work should not only include food and function studies but also blood chemistry studies.

* * *

Appreciation is expressed to Dr. S. J. Hillis for his assistance during this experiment, and also to Miss Julia Quickstad for her painstaking, and careful detail in feeding and exercising the mice. Appreciation is also extended to Dr. E. T. Bell for post-mortem tissue examinations.

MULTIPLE PRIMARY MALIGNANT TUMORS

R. C. Webb, M.D.

AND

H. M. N. Wynne, M.D.

Minneapolis

Report of Case With Adeno-carcinoma of Body of Uterus, Epithelioma of Face, Carcinoma of Stomach and Squamous Celled Carcinoma of Leg with "Cures" of Nine Years, Three and Three-fourths Years, Three and One-half Years, and Six Months Respectively, and Followed by Acute Gangrenous Appendicitis With Recovery.

Multiple cancers, according to Billroth, can only be accepted as individual and independent tumors when the histological differences preclude their being different stages of development, when each growth is shown to have sprung from its parent epithelium and when each growth has its own group of metastases.

Mercanton also adds that if one removes two cancers at one operation and the patient remains free from disease that it is practically certain that the two diseases were independent, since had either been a metastasis it is reasonable to assume the presence of other metastases which would have been incompatible with life.

Billroth reported the first cases of multiple malignancy nearly eighty years ago, and according to a study by Warren and Gates published in 1932, a total of 1259 cases have been reported. The survey by these authors was based largely on autopsy records as were Billroth's cases and many others. We feel fortunate therefore in being able to present the following report of a live patient.

A white woman, the wife of a physician, age sixty-four, para III, presented herself for examination August 7, 1929, complaining of a blood-tinged, watery vaginal discharge of two years duration. The discharge had not been offensive nor irritating. The past history is otherwise unimportant.

Physical examination revealed the following:

The external genitalia and vaginal walls were atrophic. On the posterior lip of the small cervix there was a flat nodule about one centimeter in diameter which was raised about two millimeters above the surrounding cervical tissue. The corpus was not enlarged and was regular in outline. The cervix and corpus were freely movable and there were no masses and no induration of the pelvic tissues. The entire cervical nodule was removed, and a diagnostic curettage was done on August 9, 1929. A large amount of necrotic tissue was obtained from the uterus. Frozen sections of the tissues were made and examined immediately by Dr. Floyd Grave, who made a diagnosis of adenocarcinoma of the uterus with a cervical metastasis. Radium cartridges prepared by Dr. Charles Drake were placed in the uterine cavity and in the cervical canal. A total dose of 1500 milligram hours was given. The radium was screened with 0.5 millimeter of silver and 1 millimeter of bronze encased in 1 millimeter of rubber tubing.

The patient was placed under the care of Dr. T. A. Peppard for treatment of a mild diabetes mellitus.

On November 12, 1929, a panhysterectomy was done. The uterus was slightly enlarged and boggy. There was a pedunculated tumor 3 centimeters in diameter, attached near the left uterine cornu. The tumor and endometrium were degenerating. A diagnosis of adenocarcinoma of the uterus was made after microscopic examination of sections. The patient made a good recovery from her operation and has had no evidence of any recurrence of this tumor.

In February 1935 at the age of sixty-nine she returned with a small epithelioma of the face. No pathologic sections were made of this growth. The patient was treated with roentgen rays by Dr. R. G. Allison, with recovery.

In April 1935 at the age of sixty-nine years she returned complaining of belching of gas, vague pain in the lower abdomen, considerable rumbling, vomiting on one occasion, weakness and constipation. The physical examination was essentially negative. Hemoglobin was 73 per cent; red blood cells—4,070,000; white blood cells—9,500 and differential count normal. The urine was normal.

X-ray examination revealed a carcinoma involving the pyloric end of the stomach and extending back on the greater and lesser curvatures about four or five inches. There was 80 per cent gastric retention at three hours.

At operation on April 25, 1935 the pelvic region was palpated and there was no evidence of recurrence of the carcinoma removed six years previously. The appendix was examined and did not appear abnormal. The gallbladder contained stones. The stomach contained a mass which began at the pylorus and extended upward about one and one-half inches on the lesser curvature and about five inches on the greater curvature. The lower half of the stomach was resected and an anterior Polya type gastroenterostomy with enteroanastomosis was made. The pathologic report by Dr. Margaret Smith was carcinoma of the stomach. Recovery was uneventful.

The fourth carcinoma appeared on the right leg about two inches below the knee as a small wart-like growth

which continued to grow until it was about the size of an almond. There were no other symptoms. The patient came to the hospital because of an attack of pain in the right lower quadrant of the abdomen. She had had abdominal discomfort for two or three weeks. The distress shifted about, sometimes on the left side, sometimes on the right side and sometimes beneath the costal margin on the right side. During the past forty-eight hours it had increased in intensity, and on the evening of March 29, 1938 she had been nauseated. There was slight fever, slightly increased pulse rate and slight tenderness in the lower abdomen particularly on the right side. The leucocyte count was 20,000 with 88 per cent p. m. ns. The history of carcinoma of the uterus, carcinoma of the stomach and the existence of gallstones complicated the diagnosis. The age of the patient being seventy-two years and the previous record of examination of the appendix with normal appearance caused the consultants to be very conservative. Finally, however, on March 31, 1938, we opened her abdomen for the third time and removed an appendix which was one-half inch in diameter and completely filled with pus. The appendix was not ruptured, and it was possible to explore the abdomen. Although there were a moderate number of adhesions present, a fairly satisfactory exploration was made and neither the upper abdomen nor the lower abdomen showed evidence of metastatic growths. The appendix was removed in the usual manner. On April 14, 1938 the stomach was examined with the x-ray and it was felt that there was no evidence of carcinoma.

The tumor of the right leg was removed, and microscopic examination showed it to be squamous celled carcinoma. The patient left the hospital on April 17, 1938 and is still in good health at the time of this report.

Multiple primary malignancies occur in 2 to 4 per cent of persons suffering from cancer according to Warren and Gates. These authors made a survey of the literature and added forty cases from their study of a series of 1,078 post-mortem examinations on malignant disease cases. Among the 1,259 reported cases there were 242 cases of double carcinomata of different systems and sixteen of these were primary carcinomata of the stomach and uterus (including the cervix), and three were of the stomach and bladder. In 111 cases, three or more malignant tumors were found.

Warren and Gates conclude that multiple malignant tumors occur more frequently than can be explained on the basis of chance and that this may be explained by a predisposition or susceptibility to cancer in certain persons, or the action of some factor favoring the development of malignancy.

Our patient still has gallstones. Gallstones have been credited as a factor favoring the development of malignancy. The question naturally arises in view of her demonstrated ability to survive major operations as to whether or not we should advise removal of the gallbladder or let the gallstones prove their ability to produce carcinoma in the patient with a special previous disposition or susceptibility to carcinoma.

Discussion

Dr. T. H. Sweetser: I think that you may be interested in the case of a fairly young man, just turned forty, who has survived six major operations for three entirely different malignant tumors. In 1920 our fellow member, Dr. J. F. Corbett, performed the second and third operations for glioma of the brain and there has been no recurrence of that trouble in the intervening eighteen years. In May of this year he referred the patient to me because of gross hematuria. Cystoscopy disclosed a papillary carcinoma of the bladder, and biopsy demonstrated it to be of Grade IV malignancy. I resected the bladder wall by open suprapubic cystotomy; he has had no signs or symptoms of recurrence thus far. Later he noticed blood in his stools, and proctoscopic examination by Dr. Corbett demonstrated an annular carcinoma at the lower end of the sigmoid colon. He has survived a two-stage removal of sigmoid and rectum, the growth microscopically having been of Grade IV malignancy. Of course, it is too early to say anything as to the final outcome. Such cases raise the question of the presence in certain people of some factor of susceptibility to malignancy in general. Incidentally, I understand that this man has also survived a serious automobile accident and an attack of acute pancreatitis.

Dr. Martin Nordland: I would like to know how long this patient had any symptoms of appendicitis. I noticed in examining the specimen that the appendix was not sectioned and I wondered if she might not also have a carcinoma of this organ.

Dr. R. C. Webb: I wish to thank the members for the discussion, and I believe that if you were to check your records, more cases of multiple carcinoma could be reported from this society. We have seen four other cases of multiple carcinoma.

One patient, a woman of fifty-three years, was first seen in July, 1926 and a radical operation of the left breast was performed on July 3, 1926. She returned in January, 1928, one and one-half years later, with a small carcinoma in the lower outer quadrant of the right breast. This breast was likewise removed with a radical amputation. This patient is still living, ten and one-half years after the second operation. The fact that she is still living lends some weight to the argument that the second growth was a primary one rather than a metastatic growth.

An unmarried woman, aged forty-eight, was seen in March, 1933, with a large carcinoma of the right breast. A radical operation was done. No carcinoma was found in the axillary glands. This patient was examined at intervals of three months and in March, 1934, one year later, a small lump was felt in the upper outer quadrant of the left breast which was not adherent to the chest wall or to the skin. Radical breast amputation was done and in the left axilla several large hard glands which lay high up behind the vein and artery were removed. The patient died within six months. She was treated with x-ray following both the first and second operation.

Another patient, a woman sixty-six years of age, was seen in 1923. A skin tumor of the left forearm and a skin tumor of the right side of the neck were excised with a margin of normal skin. Specimens were examined by Dr. E. T. Bell whose reports show that each was a basal cell carcinoma. This patient died ten years later of pneumonia. A postmortem examination showed no evidence of carcinoma of the internal organs.

Wynne reported a case* of primary carcinomata of the bladder and stomach before the Minneapolis Clinical Club in 1933. This case was discussed by Dr. J. C. McCartney, Jr., who had made the pathological examination of the tissue removed at the operation and performed the autopsy five years later.

As to the appendicitis, this patient was admitted to the hospital March 29, 1938, but the appendix was not removed until March 31, 1938, about forty-eight hours after admission. She had had symptoms from her gallstones off and on, but on March 28 she had had pain in the lower right abdomen without nausea. The presence of the gallstones and the two previous operations

*Wynne, H. M. N.: A case of carcinoma of the bladder removed by operation with death from carcinoma of the stomach five years after operation. Journal-Lancet, 53:168, (March 15) 1933.

for carcinoma, together with out knowledge that her appendix was normal in appearance three years previously at the age of sixty-nine, rendered the diagnosis more difficult and confusing and accounted for the delay.

INCREASED BILE FLOW AND PRESSURE AS AN AID IN THE SURGICAL AND NON-SURGICAL MANAGEMENT OF BILIARY TRACT DISEASE

R. Russell Best, M.D. (by invitation)
Omaha, Nebraska

Summary of Presentation

Frequent opening of the common duct and cholangiography have proved that common-duct stones are more common than was formerly supposed, and that stones, mucous plugs, collections of inspissated bile and blood clots which remain post-operatively not infrequently produce symptoms simulating gallbladder disease. Cholangiograms have not only done much to prove this but have aided considerably in reaching a better understanding of the physiology and mechanism of the extrahepatic biliary tract. Spasticity of the sphincter of Oddi, or spastic biliary dyssynergia, may exist to the degree of completely blocking the lower end of the common duct, and increase in common duct pressure associated with this spasm may well be the cause of symptoms in the post-cholecystectomy syndrome. Various antispasmodic drugs have been used to relax the sphincter area, nitroglycerin and atropine being most commonly employed. Then by stimulating bile flow along the bile highways, namely the intrahepatic, hepatic and common ducts, a biliary flush has been obtained. This increased bile flow is accomplished by administering dehydrocholic acid (decholin and procholon). Studies have been made and curves plotted to show the increase of bile flow and bile pressure (Figs. 1 and 2). After three or four days administration of dehydrocholic acid, the pressure tends to return to normal, but after withdrawing it for a few days, the pressure may again be increased by its administration. Cases were presented in which delayed cholangiograms revealed single stones, multiple stones, or other debris in the common duct and which demonstrated the flushing out of these foreign bodies by increasing the bile flow and relaxing the sphincter area. In several instances where the stones were too large to pass through the relaxed sphincter area, the method was not successful.

Immediate cholangiograms are not taken as often since the introduction of this biliary flush, for the smaller foreign bodies which in the past probably remained in the common duct without being properly appreciated or suspected, may now be removed quite easily by this method without proving their existence.

In every case with a common duct T-tube or catheter, a cholangiogram should be made before the tube or catheter is withdrawn. A 48 per cent hippuran solution has proved to be the most advantageous contrast medium, 15 to 40 c.c. usually being necessary. An immediate radiograph is taken, after which the contrast medium is permitted to escape from the tube for five minutes, and then the cholangiogram is repeated.

The following three-day regime is instituted some ten days after every cholecystectomy; it is also used in all patients who have previously had their gallbladders removed and that have residual symptoms, and in the routine medical management of gallbladder disease. It may be necessary to repeat the treatment a number of times or at intervals in some cases because latent infection of the ductal system may result in secondary formation of common duct stones and debris. This method may also prove to be the means of dislodging stones from the liver into the common duct.

1. Dehydrocmolic acid tablets, 3¼ grain, are given t.i.d. after meals and at bedtime for three days.
2. One-half ounce of magnesium sulphate is given each morning.
3. One ounce of pure cream or olive oil is given before the noon and evening meals and at bedtime.
4. On the first day, 1/100 grain nitroglycerin is dissolved under the tongue t.i.d. before meals.
5. On the second day, 1/100 grain atropine is given in a little water before meals.
6. On the third day, the nitroglycerin is repeated.
7. If a T-tube or catheter is present in the common duct, or if a fistula exists, inject warm saline solution each day and follow with warm olive oil. Warm lipoiodine is beneficial at times.

Jaundice with complete obstruction of the common duct contraindicates this method of treatment.

Discussion

Dr. A. A. Zierold.—This evening I have heard a great deal that is interesting and stimulating. I cannot help but have a feeling of admiration for someone who can so boldly enter a field that is hedged about with so much controversy as is the biliary system.

Until about 1900 most surgeons felt that the treatment of fractures was reasonably good. They were quite satisfied with the results on the whole until the x-ray appeared. Immediately they became dissatisfied with their results. Widespread use of the cholangiogram may bring about a similar state of affairs. Either my experience has been too small or I have not been sufficiently accurate in my observations, but for the most part, I have been satisfied that people who had stones in their gallbladders and had them removed, had a reasonably good convalescence and subsequent course. After seeing Dr. Best's studies and hearing him talk, I am not at all so sure that this is the case. It may be that patients whom I assumed were symptom-free were going to someone else and detailing their symptoms to them.

Undoubtedly there must be a much greater number of cases with residual symptoms due to the original condition for which they were operated upon or treated than we appreciate. It seems also not unreasonable to suppose that of this number a great many must obtain relief spontaneously without any particular treatment. Undoubtedly a number of them must pass stones from time to time without any special treatment.

I am impressed with what Dr. Best said with regard to dysfunction of the sphincter of Oddi, which most satisfactorily explains for me the symptoms of the patient who presents for surgery with an apparently normal gallbladder without stones. It is much easier to reconcile their symptoms upon this assumption and I believe that in the absence of satisfactory x-ray findings and persistence of symptoms simulating colic a most exhaustive study should be conducted to determine whether or not this may not be a case of dysfunction of the sphincter.

With regard to the digestive symptoms of gallblad-

der disease, I cannot help but feel that these symptoms are of dysfunction of the common duct rather than symptoms of gallbladder disease itself. It is hard for me to believe or to consider the gallbladder disease

One thing I was interested in observing in Dr. Best's cholangiograms was the appearance of the pancreatic duct and I rather expected him to say something with regard to pancreatic reflux. It seems quite reasonable

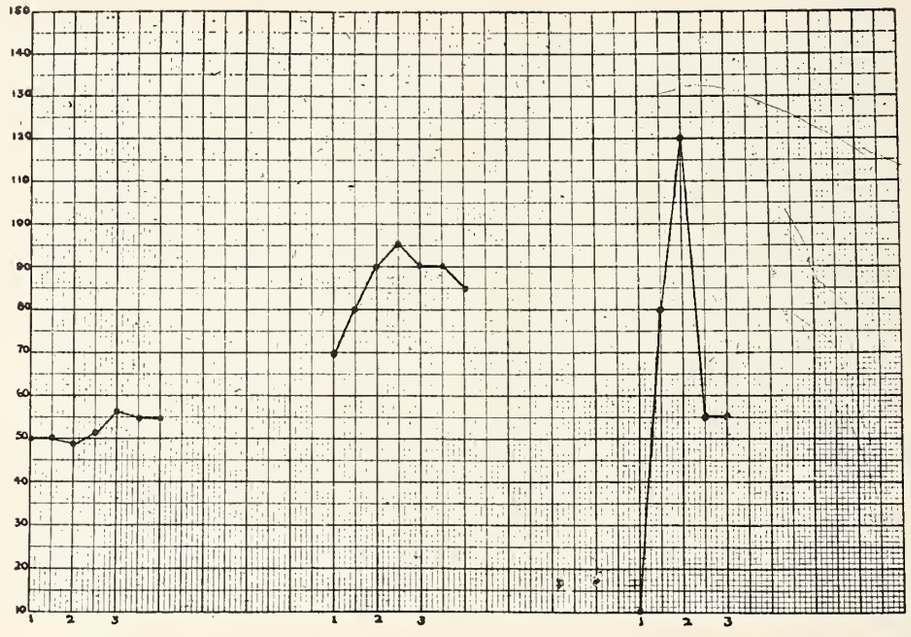

Fig. 1. Following administration of dehydrocholic acid, the general level of the intraductal pressure is increased as compared with the control level. The intravenous injection of sodium dehydrocholate results in a sudden but not prolonged rise.

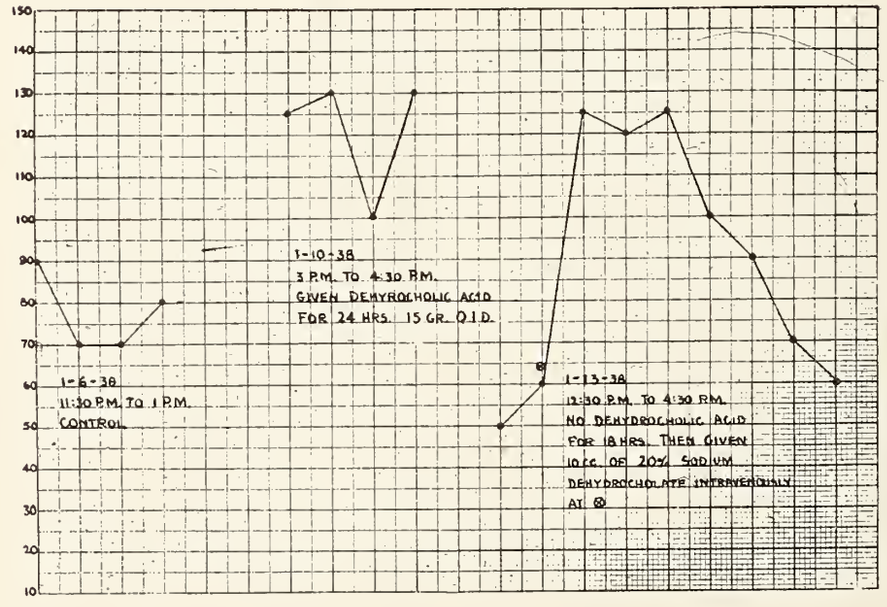

Fig. 2. Plotted curve of another patient, giving similar result. During the period of increased pressure and aided by a relaxed sphincter area a flushing out effect is provided.

which we characterize by stone formation, and fibrosis of the gallbladder wall, as an inflammatory or bacterial phenomenon. To my mind it is more the evidence of foreign body or chemical reaction. The treatment of it as an infectious process is rather difficult for me to accept. I am impressed more and more, particularly from what Dr. Best said, that many of the symptoms which we consider as chronic inflammatory disease of the gallbladder are disturbances of function or sphincter control of the emptying of the common duct.

to me that many changes in the duct as well as the gallbladder may be a result of a pancreatic reflux. The frequency with which pancreatic secretion may be obtained from the gallbladder bile is sufficient to make it a matter of importance and a matter worthy of further investigation.

I did not quite understand whether Dr. Best implied that the relaxation of the sphincter obtained by diet and nitroglycerin, atrophine, etc., was intended to overcome the spasticity of the sphincter only temporarily or permanently and whether it could be first

obtained by drug action and then later perpetuated by diet. In that regard, I would appreciate his ideas as to the reasonableness of the attempts at dilatation or even section of the sphincter of Oddi.

Dr. Best spoke of stones occurring in the liver. It is hard to believe that all of these stones in the biliary tract have been shoved up by palpation and manipulation by the surgeon. Certainly indications are that many of these may be formed outside the gallbladder. We know that following the removal of the gallbladder there is a distention or dilatation of the common duct. It is reasonable to suppose that we may be turning the common duct into a functioning gallbladder. It is not unreasonable to suppose that should this obtain for any length of time stones may be developed within the common duct and within the major biliary passages in the same manner that they were formed as metabolic disturbances within the gallbladder itself. If this should hold true with the gallbladder removed, certainly it would be equally tenable in the case of the old fibrotic gallbladder which no longer concentrates and which in many instances is obstructed at the cystic duct.

This has been a most interesting and most stimulating talk, and I wish to thank Dr. Best for the opportunity of hearing him.

Dr. E. A. Boyden (by invitation).—There are only a few words I wish to say because Dr. Best and I had our discussion this afternoon. As he talked, there were a number of things of interest that occurred to me. The first was suggested by his picture of the muscle of the gallbladder. There has been some recent physiological work at the University of Graz which demonstrates that the contraction of the gallbladder begins at the fundus, even as we had predicted from our early study of cholecystograms; then appears in the infundibulum, which, in turn, expels the bile.

Another point of interest was his mention of possible occlusion of the common duct by blood clots or debris. This is understandable in the light of Dr. Baggenstoss' recent observation that as soon as the common bile duct reaches the window in the intestinal muscle it tapers off abruptly. The same is true of the pancreatic duct. It is quite reasonable therefore that clots, for a while at least, may cause stasis.

I cannot feel enthusiastic, however, about Dr. Best's interpretation of the use of atropine in relaxing the neck of the gallbladder. Aside from skepticism concerning the "collum-cysticus" sphincter, our work has tended to raise serious doubts as to whether the human gallbladder is under the control of motor nerves. Unquestionably the animal gallbladder is. If one feeds egg-yolk to a cat that has previously had an electrode sewed to its stomach, the gallbladder will begin to empty. Then if a tetanizing current is sent through, reflexes passing from stomach to biliary tract will inhibit the emptying of the gallbladder. The same result is readily obtained by stimulating other portions of the gut tract. But if similar experiments are tried on human beings who have swallowed an electrode, the gallbladder continues to empty normally, as evidenced by frequent cholecystograms, even though the colicky pain induced by the current is severe. This has led us to suspect that there is a striking species difference in this respect between man and the smaller animals and that the human gallbladder is controlled primarily by hormones. Accordingly, I would like to ask Dr. Best whether he merely had a "hunch" that atropine would relax the gallbladder or whether he had any evidence that would permit one to discriminate between the action of nitroglycerine and that of atropine.

You physicians, of course, are primarily interested in the amelioration and prevention of disease and those of us in the fundamental sciences are most interested in the explanation of biological phenomena, but neither of us will solve our problems without the help of the other. As an illustration of this point I would like to mention not only Dr. Best's contributions but also Dr. Leven's recent studies in the University Hospital. When some of us were working out the development of the sphincter of Oddi in the human fetus we came to the conclusion that the principal muscle in the duodenal portion of the bile passage lies around the common bile duct just before it joins the ampulla of Vater, and that this is the sphincter which causes the filling of the gallbladder. We also observed in these fetuses some muscle around the ampulla. But it was clear that the important muscle, physiologically, is the sphincter choledochus. Meanwhile Dr. Leven was finding that in 20 per cent of his cholangiograms there was indication of a reflux of contrast media into the pancreatic duct. This implied the existence of a strong sphincter ampullæ. With these new observations in mind Mr. Kreilkamp and I began examining macerated adult sphincters of Oddi, and found that one of every six autospy specimens exhibited a prominent sphincter ampullæ in addition to a well developed sphincter choledochus. It is quite possible, therefore, that the patients that show refluxes of this sort are those in whom there is an atypical development of muscle around the ampulla of Vater. What is physiologically important, therefore, is not always the most important clinically.

In conclusion, I would like to join Dr. Zierold in thanking Dr. Best for a most interesting and instructive evening.

Dr. N. Logan Leven (by invitation).—I was very much interested in this excellent paper. This matter of evacuating stones from the common bile duct brings to mind a case reported by Neuwirt in 1930. In a case of persistent biliary fistula he demonstrated three stones in the common bile duct by injecting iodized oil into the fistula. He planned to operate on this case the next day but on the following morning he found a pea-sized gallstone at the external opening of the fistula. A second somewhat larger stone was found in the stool the following day. The fistula promptly closed and the patient remained well. He ascribed the passage of stones to the cholangiography. The viscid oily solution remained on the surface of the stone and the mucous membrane lining of the bile duct. It is natural that a stone which has become slippery passes more easily through a slippery passage than a rough surface stone, especially if through the injection of a large amount of fluid the pressure in the bile passages becomes raised. In this case a small stone plugged the fistula, allowing an increased intraductal pressure to occur.

A similar procedure has long been used in the removal of ureteral stones where in cases of smaller stones spontaneous passage of the stone may occur following injection of oil into the ureter.

I would like to ask Dr. Best whether he has ever seen a case following cholangiography of the syndrome simulating the acute pancreatic edema described by Zoepfel.

Mallet-Guy, Beaupere and Armanet, Walzel, Sturm and others have reported such cases. I had one case in a series of 200 cholangiograms where following reflux into the pancreatic duct the patient on the following day developed abdominal pain, nausea, vomiting and a temperature of 103.8 degrees. By the second day the symptoms had subsided.

Dr. George S. Bergh.—The administration of a choleretic together with a drug intended to produce relaxation of the sphincter of Oddi, as Dr. Best has suggested as a means of favoring the passage of stones from the common bile duct into the duodenum, appears to be based upon physiologically sound principles. The objection that I would have concerns his selection of atropine as a drug to produce sphincter relaxation.

Although it appears to be fairly well established that atropine will produce relaxation of the sphincter in some laboratory animals, our experience, based upon direct observations in patients with choledochostomy tubes, indicates that this drug has no significant effect upon the sphincter in man. Amyl nitrite and nitroglycerin, on the other hand, will produce relaxation.

We have found that Dr. Boyden's fatty meal of egg yolks and cream sometimes will cause relaxation of a spastic sphincter when drugs such as amyl nitrite and nitroglycerin have failed. This suggests the possibility that such a meal might prove useful as a means of producing sphincter relaxation in cases similar to those presented by Dr. Best, but we have had no clinical experience with it along that line.

Dr. R. Russell Best (closing).—Dr. Zierold mentioned a very practical point which was also brought out by Dr. Boyden—that probably stones and debris are often passed from the common duct with very little pain. I believe this is true, and it has no doubt been the saving point about gallbladder surgery. The purpose of this form of treatment is to flush out the ductal system, whether a spastic or atonic sphincter exists. Nitroglycerin and atropine, with or without a biliary flush, are indicated in spastic dyssynergia. Those with an atonic spincter probably should have a biliary flush periodically in order to guard against an ascending infection.

In regard to the instrumentation advocated by several authors, I might say that we use the smaller Bake dilators but never the large dilators, for I think they tear the muscle. The cutting instrument shown by Dr. Doubilet of New York might also prove harmful.

We do not believe nitroglycerin relaxes the sphincter in all cases, and our investigation has shown the same to be true of atropine. Therefore, in our three-day regime we have combined the two.

We have had quite a number of cases where the pancreatic duct was visible, as shown in the cholangiogram, but we believe there is no danger attached to the reflux of the opaque material into the pancreatic duct.

* * *

The meeting adjourned.

Harvey Nelson, M.D., *Secretary.*

CLASSIFIED ADVERTISING

FOR SALE—Fisher diathermy, McIntosh diathermy, cold quartz ultra violet ray, infra red, incubator, centrifuge, surgical instruments. 580 Portland Avenue, Saint Paul. DAle 1792.

WANTED—Physician to assist surgeon in payment for office expenses. Good opportunity to build up practice in Minneapolis. Give references and school. Address A-59, care of Minnesota Medicine.

GOOD OPPORTUNITY for doctor to locate in town of 500 population in prosperous farming community in Southern Minnesota. Write A-55, care Minnesota Medicine.

LOCUM TENENS or ASSISTANTSHIP desired. Completing 18 months rotating interneship Minneapolis General Hospital, January 1. Licensed in in Minnesota. Write A-56, care Minnesota Medicine.

TECHNICIAN DESIRES POSITION in hospital or doctor's office in Twin Cities. Research or routine; good experience; no x-ray; references. Address Mary Driscoll Worman, 645 Goodrich Avenue, St. Paul. Dale 0245.

POSITION WANTED—X-ray and laboratory technician with year and half experience; also qualified in physiotherapy, electrocardiography, bookkeeping. Dorothy Traver, Thief River Falls, Minnesota.

FOR SALE—Thriving practice in Saint Paul. Physician taking institutional practice. Address A-58, care Minnesota Medicine.

WHY PAY HIGH OFFICE RENT when you can get more space and better accommodations for less money in the Elliot Building, 8th Street and 8th Avenue South, Minneapolis. Centrally located; convenient to hospitals and outside restricted parking zone. Equipped with x-ray and clinical laboratory. H. W. Quist, M.D., 732 Eighth Ave. So., Minneapolis, Minn.
